

UM3758 Series

Tri-State Programmable Encoder/Decoder

Features

- Single-Chip CMOS construction
- Single-Chip **encoder/decoder** selected by jump wire
- Wide operating voltage range : V_{Do} = 3 to 12 Volts
- Built-in RC oscillator (can use 5 % resistor)
- Easy interface with RF, **Infrared(IR)** and **Ultrasonic** transmission media
- Tri-state(0, 1, open) address codes, some of address

codes used as data **codes** or as internal addresses by mask **option**

- Internal address **code** is **18-bit**, ie $3^{18} = 387,428, 489$ different **codes** at most
- Decoder has **8-bit** latch data
- Series IC for various applications
- **UM3758-120A** pin outcompatible to UM3750

General Description

The UM3758 series are **single-chip** programmable **encoder/decoder** ICs fabricated in CMOS structure for low power consumption. They are enhanced for new stage encoder/decoder ICs to provide many more combinations for **higher security**.

Most combinations are achieved by **UM3758-180A**, providing $3^{18} = 387,420,489$ combinations. Some ICs of this series provide 4 to 8 data bits for controlling.

According to the following information, The **internal address bits**, **18 bits/24-pin** and **12 bits/18-pin package**, can be assigned by customer in **advance** for **much higher security** and confidentialii. Whenever the address **codes** of **transmitter** transmits, the **receiver** will check the address codes with his own and the successive two **matched** address codes will generate a low pulse. If there were any data bits, the **receiver** will latch these data bis at the corresponding pins for controlling.

Pin Configurations

Pin Configurations (Continued)

Absolute Maximum Ratings*

Power Supply Voltage -0.3V to 11V
 Operating Temperature -20°C to 70°C
 Storage Temperature (Tstg) -55°C to 150°C
 Apply Voltage on any Pin
 $V_{SS} - 0.3 < V_{IN} < V_{DD} + 0.3$

***Comments**

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only. Functional Operation of this device at these or any other conditions above those indicated in the operational sections of this specification is not implied and exposure to absolute

DC Electrical Characteristics

($T_A = 25^\circ\text{C}$, $V_{DD} = 9$ Volts, $V_{SS} = 0\text{V}$ unless otherwise specified)

Parameter	Symbol	Min.	Typ.	Max.	Unit	Conditions

Functional Description

General

The operating mode of the UM3756 series is controlled by the MODE pin. When the 'MODE' pin is connected to VDD the circuit will automatically switch to encoder mode, then "TX/RX OUT" pin acts as data out pin and 'RX INP' pin act as an idle pin. When 'MODE' pin is connected to VSS the circuit will switch to decoder mode, then "TX/RX OUT" pin will switch to LOW if comparison is OK, otherwise this pin will keep HIGH, and "RX/INP" receives waveform from detect circuit.

Encoder Mode

The encoder mode is selected by connecting "MODE" pin to VDD.

The transmit sequence is initiated by the power connection and continuously transmits till power down. Each transmitted address bit is encoded into address

pulses (see Fig. 1). A logic zero is encoded as two consecutive long pulses, a logic one as two consecutive short pulses and an open as a long pulse followed by a short pulse. Each transmitted data bit is encoded into logic zero or one and the data pulse is the same as the address pulse (see Fig. 1), ie., the state of data pin is either one or zero. The data is one when connected to VDD or open and zero when connected to VSS.

The UM3758-180A samples the 18 bit tri-state address and encodes this parallel address data for transmitting. These 16 address pins may be in either of three states (0, 1, open) allowing $3^{18} = 387,420,489$ possible combinations then the UM3758-120A provides 12-bit address and allows $3^{12} = 531,441$ possible combinations.

The UM3758-108A/B and UM3758-084A/B provide address bits and data bits, as described in Table 1.

Part Number	Address Bits	Address Combinations	Data Bits	Data Combinations
UM3758-108A/B/AM/BM	10	59,049	8	256
UM3758-084A/B/AM/BM	a	6,561	4	16

Table 1

Decoder Mode

The decoder mode is selected by connecting "MODE" pin to vss.

The decoder receives the serial data from the detect circuit and outputs the comparison result or data, if it is valid. The received data may include two types — without data and with data.

For decoder without data ICs, such as UM3758-180A and UM3758-120A the address word is examined bit by bit as received; if two successive address words match the address bis of decoder, the "TX/RX OUT" pin will switch to LOW and two successive unmatched address words will cause "TX/RX OUT" pin to return to HIGH (see Fig. 3-1).

For decoder with data IC, such as UM3758-108A/B and UM3758-084A/B, the address word with data word are examined bit by bi as received. The first 10 bits

(ex. UM3758-108A/B) are assumed to be address bi. If the address bits match the address bits from detect circuit, the next eight data bits are stored and matched to the last valid data stored. When the second word with data is received, the address bis must match again, and if it does, the data bits are checked against the previous stored data biis. If the two words (eight bits data each) of data match, the data is transferred to the output data pins (D1, D2 to D8). If the decoder is momentary type, the data pins will latch the data till the "TX/RX OUT" pin switches to HIGH; for latch decoder, the data pins will latch the data till the next valid data appears (see Fig. 3-2). Although the address bits are tri-state (0, 1, open), the data information must be either one or zero. An open state will be decoded as a logic one. The above table (Table 1) also describes these (decoder with data).
