## MaverickKey<sup>™</sup> Unique ID

MaverickKey unique hardware programmed IDs are a solution to the growing concern over secure web content and commerce. With Internet security playing an important role in the delivery of digital media such as books or music, traditional software methods are quickly becoming unreliable. The MaverickKey unique IDs provide OEMs with a method of utilizing specific hardware IDs such as those assigned for SDMI (Secure Digital Music Initiative) or any other authentication mechanism.

Both a specific 32-bit ID as well as a 128-bit random ID is programmed into the EP9301 through the use of laser probing technology. These IDs can then be used to match secure copyrighted content with the ID of the target device the EP9301 is powering, and then deliver the copyrighted information over a secure connection. In addition, secure transactions can benefit by also matching device IDs to server IDs. MaverickKey IDs provide a level of hardware security required for today's Internet appliances.

## General Purpose Memory Interface (SDRAM, SRAM, ROM, FLASH)

The EP9301 features a unified memory address model where all memory devices are accessed over a common address/data bus. Memory accesses are performed via the Processor bus. The SRAM memory controller supports 8- and 16-bit devices and accommodates an internal boot ROM concurrently with 16-bit SDRAM memory.

- 1 to 4 banks of 16-bit, 66 MHz SDRAM

## Universal Asynchronous Receiver/Transmitters (UARTs)

Two 16550-compatible UARTs are supplied. One provides asynchronous HDLC (High-level Data Link Control) protocol support for full duplex transmit and receive. The HDLC receiver handles framing, address matching, CRC checking, control-octet transparency, and optionally passes the CRC to the host at the end of the packet. The HDLC transmitter handles framing, CRC generation, and control-octet transparency. The host must assemble the frame in memory before transmission. The HDLC receiver and transmitter use the UART FIFOs to buffer the data streams. The second UART provides IrDA<sup>®</sup> compatibility.

- UART1 supports modem bit rates up to 115.2 kbps, supports HDLC and includes a 16 byte FIFO for receive and a 16 byte FIFO for transmit. Interrupts are generated on Rx, Tx and modem status change.
- UART2 contains an IrDA encoder operating at either the slow (up to 115 kbps), medium (0.576 or 1.152 Mbps), or fast (4 Mbps) IR data rates. It also has a 16 byte FIFO for receive and a 16 byte FIFO for transmit.

## Timers

The Watchdog Timer ensures proper operation by requiring periodic attention to prevent a reset-on-time-out.

Two 16-bit timers operate as free-running down counters or as periodic timers for fixed-interval interrupts and have a range of 0.03 ms to 4.27 seconds.

One 32-bit timer, plus a 6-bit prescale counter, has a range of 0.03  $\mu$ s to 73.3 hours.

One 40-bit debug timer, plus a 6-bit prescale counter, has a range of 1.0  $\mu$ s to 12.7 days.

## Interrupt Controller

The interrupt controller allows up to 54 interrupts to generate an Interrupt Request (IRQ) or Fast Interrupt Request (FIQ) signal to the processor core. Thirty-two hardware priority assignments are provided for assisting IRQ vectoring, and two levels are provided for FIQ vectoring. This allows time-critical interrupts to be processed in the shortest time possible. Internal interrupts may be programmed as active high or active low level sensitive inputs. GPIO pins programmed as interrupts may be programmed as active high level sensitive, active low level sensitive, rising edge triggered, falling edge triggered, or combined rising/falling edge triggered.

- Supports 54 interrupts from a variety of sources (such as UARTs, GPIO and ADC)
- Routes interrupt sources to either the ARM920T's IRQ or FIQ (Fast IRQ) inputs
- Three dedicated off-chip interrupt lines INT[2:0] operate as active-high level-sensitive interrupts
- Any of the 19 GPIO lines maybe configured to generate interrupts

- Software supported priority mask for all FIQs and IRQs

**Table K. External Interrupt Controller Pin Assignment**

## 12-channel DMA Controller

The DMA module contains 12 separate DMA channels. Ten of these may be used for peripheral-to-memory or memory-to-peripheral access. Two of these are dedicated to memory-to-memory transfers. Each DMA channel is connected to the 16-bit DMA request bus.

The request bus is a collection of requests, Serial Audio and UARTs. Each DMA channel can be used independently or dedicated to any request signal. For each DMA channel, source and destination addressing can be independently programmed to increment, decrement, or stay at the same value. All DMA addresses are physical, not virtual addresses.

## Internal Boot ROM

The Internal 16 kbyte ROM allows booting from FLASH memory, SPI or UART. Consult the EP93xx User's Manual for operational details.

## ADC

Parameter	Comment	Value	Units
Resolution	No missing codes Range of 0 to 3.3 V	50K counts (approximate)	
Integral non-linearity		0.01%	
Offset error		±15	mV
Full scale error		0.2%	
Maximum sample rate	ADIV = 0 ADIV = 1	3750 925	Samples per second Samples per second

Note: ADIV refers to bit 16 in the KeyTchClkDiv register.  
 ADIV = 0 means the input clock to the ADC module is equal to the external 14.7456 MHz clock divided by 4.  
 ADIV = 1 means the input clock to the ADC module is equal to the external 14.7456 MHz clock divided by 16.

### Using the ADC:

This ADC has a state-machine based conversion engine that automates the conversion process. The initiator for a conversion is the read access of the TSXYResult register by the CPU. The data returned from reading this register contains the result as well as the status bit indicating the state of the ADC. However, this peripheral requires a delay between each successful conversion and the issue of the next conversion command, or else the returned value of successive samples may not reflect the analog input. Since the state of the ADC state machine is returned through the same channel used to initiate the conversion process, there must be a delay inserted after every complete conversion. Note that reading TSXYResult during a conversion will not affect the result of the ongoing process.

The following is a recommended procedure for safely polling the ADC from software:

1. Read the TSXYResult register into a local variable to initiate a conversion.
2. If the value of bit 31 of the local variable is '0' then repeat step 1.
3. Delay long enough to meet the maximum sample rate as shown above.
4. Mask the local variable with 0xFFFF to remove extraneous data.
5. If signed mode is used, do a sign extend of the lower halfword.
6. Return the sampled value.
