

Features

- 100MHz gain-bandwidth
- Gain-of-2 stable
- Low supply current (per amplifier) - 5.2mA at $V_S = \pm 15V$
- Wide supply range - 2.5V to 36V
- High slew rate - 275V/ μs
- Fast-settling - 80ns to 0.1% for a 10V step
- Low differential gain - 0.02% at $A_V = +2$, $R_L = 150\Omega$
- Low differential phase - 0.07° at $A_V = +2$, $R_L = 150\Omega$
- Wide output voltage swing - $\pm 13.6V$ with $V_S = \pm 15V$, $R_L = 1k\Omega$

Applications

- Video amplifiers
- Single-supply amplifiers
- Active filters/integrators
- High speed signal processing
- ADC/DAC buffers
- Pulse/RF amplifiers
- Pin diode receivers
- Log amplifiers

General Description

The EL2245C and EL2445C are dual and quad versions of the popular EL2045C. They are high speed, low power, low cost monolithic operational amplifiers built on Elantec's proprietary complementary bipolar process. The EL2245C and EL2445C are gain-of-2 stable and feature a 275V/ μs slew rate and 100MHz bandwidth at gain-of-2 while requiring only 5.2mA of supply current per amplifier.

The power supply operating range of the EL2245C and EL2445C is from $\pm 18V$ down to as little as $\pm 2V$. For single-supply operation, the EL2245C and EL2445C operate from 36V down to as little as 2.5V. The excellent power supply operating range of the EL2245C and EL2445C makes them an obvious choice for applications on a single +5V or +3V supply.

The EL2245C and EL2445C also feature an extremely wide output voltage swing of $\pm 13.6V$ with $V_S = \pm 15V$ and $R_L = 1k\Omega$. At $\pm 5V$, output voltage swing is a wide $\pm 3.8V$ with $R_L = 500\Omega$ and $\pm 3.2V$ with $R_L = 150\Omega$. Furthermore, for single-supply operation at +5V, output voltage swing is an excellent 0.3V to 3.8V with $R_L = 500\Omega$.

At a gain of +2, the EL2245C and EL2445C have a -3dB bandwidth of 100MHz with a phase margin of 50°. Because of their conventional voltage-feedback topology, the EL2245C and EL2445C allow the use of reactive or non-linear elements in their feedback network. This versatility combined with low cost and 75mA of output-current drive make the EL2245C and EL2445C an ideal choice for price-sensitive applications requiring low power and high speed.

Applications Information

Product Description

The EL2245C and EL2445C are dual and quad low-power wideband monolithic operational amplifiers built on Elantec's proprietary high-speed complementary bipolar process. The EL2245C and EL2445C use a classical voltage-feedback topology which allows them to be used in a variety of applications where current-feedback amplifiers are not appropriate because of restrictions placed upon the feedback element used with the amplifier. The conventional topology of the EL2245C and EL2445C allows, for example, a capacitor to be placed in the feedback path, making it an excellent choice for applications such as active filters, sample-and-holds, or integrators. Similarly, because of the ability to use diodes in the feedback network, the EL2245C and EL2445C are an excellent choice for applications such as fast log amplifiers.

Power Dissipation

With the wide power supply range and large output drive capability of the EL2245C and EL2445C, it is possible to exceed the 150°C maximum junction temperatures under certain load and power-supply conditions. It is therefore important to calculate the maximum junction temperature (T_{JMAX}) for all applications to determine if power supply voltages, load conditions, or package type need to be modified for the EL2245C and EL2445C to remain in the safe operating area. These parameters are related as follows:

$$T_{JMAX} = T_{MAX} + (\theta_{JA} \times PD_{MAXTOTAL})$$

where:

$PD_{MAXTOTAL}$ is the sum of the maximum power dissipation of each amplifier in the package (PD_{MAX}). PD_{MAX} for each amplifier can be calculated as follows:

$$PD_{MAX} = 2 \times V_S \times I_{SMAX} + (V_S - V_{OUTMAX}) \times \frac{V_{OUTMAX}}{R_L}$$

where:

T_{MAX} = Maximum ambient temperature

θ_{JA} = Thermal resistance of the package

PD_{MAX} = Maximum power dissipation of each amplifier

V_S = Supply voltage

I_{SMAX} = Maximum supply current of each amplifier

V_{OUTMAX} = Maximum output voltage swing of the application

R_L = Load resistance

To serve as a guide for the user, we can calculate maximum allowable supply voltages for the example of the video cable-driver below since we know that $T_{JMAX} = 150^\circ\text{C}$, $T_{MAX} = 85^\circ\text{C}$, $I_{SMAX} = 7.6\text{mA}$ per amplifier, and the package θ_{JA} s are shown in Table 1. If we assume (for this example) that we are driving a back-terminated video cable, then the maximum average value (over duty-cycle) of V_{OUTMAX} is 1.4V, and $R_L = 150\Omega$, giving the results seen in Table 1.

Table 1

Part	Package	θ_{JA}	Max PDiss @ T_{MAX}	Max V_S
Duals				
EL2245CN	PDIP8	100°C/W	0.650W @85°C	±16.6V
EL2245CS	SO8	160°C/W	0.406W @85°C	±10.5V
Quads				
EL2445CN	PDIP14	81°C/W	0.802W @85°C	±11.5V
EL2445CS	SO14	120°C/W	0.542W @85°C	±7.5V

Single-Supply Operation

The EL2245C and EL2445C have been designed to have a wide input and output voltage range. This design also makes the EL2245C and EL2445C an excellent choice for single-supply operation. Using a single positive supply, the lower input voltage range is within 100mV of ground ($R_L = 500\Omega$), and the lower output voltage range is within 300mV of ground. Upper input voltage range reaches 4.2V, and output voltage range reaches 3.8V with a 5V supply and $R_L = 500\Omega$. This results in a 3.5V output swing on a single 5V supply. This wide output voltage range also allows single-supply operation with a supply voltage as high as 36V or as low as 2.5V. On a single 2.5V supply, the EL2245C and EL2445C still have 1V of output swing.

EL2245C, EL2445C*Dual/Quad Low-Power 100MHz Gain-of-2 Stable Op Amp***Gain-Bandwidth Product and the -3dB Bandwidth**

The EL2245C and EL2445C have a bandwidth at gain-of-2 of 100MHz while using only 5.2mA of supply current per amplifier. For gains greater than 4, their closed-loop -3dB bandwidth is approximately equal to the gain-bandwidth product divided by the noise gain of the circuit. For gains less than 4, higher-order poles in the amplifiers' transfer function contribute to even higher closed loop bandwidths. For example, the EL2245C and EL2445C have a -3dB bandwidth of 100MHz at a gain of +2, dropping to 20MHz at a gain of +5. It is important to note that the EL2245C and EL2445C have been designed so that this "extra" bandwidth in low-gain applications does not come at the expense of stability. As seen in the typical performance curves, the EL2245C and EL2445C in a gain of +2 only exhibit 1.0dB of peaking with a 1k Ω load.

Video Performance

An industry-standard method of measuring the video distortion of components such as the EL2245C/EL2445C is to measure the amount of differential gain (dG) and differential phase (dP) that they introduce. To make these measurements, a 0.286V_{pp} (40 IRE) signal is applied to the device with 0V DC offset (0 IRE) at either 3.58MHz for NTSC or 4.43MHz for PAL. A second measurement is then made at 0.714V DC offset (100 IRE). Differential gain is a measure of the change in amplitude of the sine wave, and is measured in percent. Differential phase is a measure of the change in phase, and is measured in degrees.

For signal transmission and distribution, a back-terminated cable (75 Ω in series at the drive end, and 75 Ω to ground at the receiving end) is preferred since the impedance match at both ends will absorb any reflections. However, when double termination is used, the received signal is halved; therefore a gain of 2 configuration is typically used to compensate for the attenuation.

The EL2245C and EL2445C have been designed as an economical solution for applications requiring low video distortion. They have been thoroughly characterized for video performance in the topology described above, and the results have been included as typical dG and dP

specifications and as typical performance curves. In a gain of +2, driving 150 Ω , with standard video test levels at the input, the EL2245C and EL2445C exhibit dG and dP of only 0.02% and 0.07° at NTSC and PAL. Because dG and dP can vary with different DC offsets, the video performance of the EL2245C and EL2445C has been characterized over the entire DC offset range from -0.714V to +0.714V. For more information, refer to the curves of dG and dP vs DC Input Offset.

Output Drive Capability

The EL2245C and EL2445C have been designed to drive low impedance loads. They can easily drive 6V_{pp} into a 150 Ω load. This high output drive capability makes the EL2245C and EL2445C an ideal choice for RF, IF and video applications. Furthermore, the current drive of the EL2245C and EL2445C remains a minimum of 35mA at low temperatures.

Printed-Circuit Layout

The EL2245C and EL2445C are well behaved, and easy to apply in most applications. However, a few simple techniques will help assure rapid, high quality results. As with any high-frequency device, good PCB layout is necessary for optimum performance. Ground-plane construction is highly recommended, as is good power supply bypassing. A 0.1 μ F ceramic capacitor is recommended for bypassing both supplies. Lead lengths should be as short as possible, and bypass capacitors should be as close to the device pins as possible. For good AC performance, parasitic capacitances should be kept to a minimum at both inputs and at the output. Resistor values should be kept under 5k Ω because of the RC time constants associated with the parasitic capacitance. Metal-film and carbon resistors are both acceptable, use of wire-wound resistors is not recommended because of their parasitic inductance. Similarly, capacitors should be low-inductance for best performance.

The EL2245C and EL2445C Macromodel

This macromodel has been developed to assist the user in simulating the EL2245C and EL2445C with surrounding circuitry. It has been developed for the PSPICE simulator (copyrighted by the Microsim Corporation), and may need to be rearranged for other

EL2245C, EL2445C

Dual/Quad Low-Power 100MHz Gain-of-2 Stable Op Amp

simulators. It approximates DC, AC, and transient response for resistive loads, but does not accurately model capacitive loading. This model is slightly more complicated than the models used for low-frequency op-amps, but it is much more accurate for AC analysis.

The model does not simulate these characteristics accurately:

- Noise
- Settling time
- Non-linearities
- Temperature effects
- Manufacturing variations
- CMRR
- PSRR
