

Features

- 130 MHz 3 dB bandwidth ($A_V = +2$)
- 180 MHz 3 dB bandwidth ($A_V = +1$)
- 0.01% differential gain, $R_L = 500\Omega$
- 0.01° differential phase, $R_L = 500\Omega$
- Low supply current, 7.5 mA per amplifier
- Wide supply range, $\pm 2V$ to $\pm 15V$
- 80 mA output current (peak)
- Low cost
- 1500 V/ μs slew rate
- Input common mode range to within 1.5V of supplies
- 35 ns settling time to 0.1%

Applications

- Video amplifiers
- Cable drivers
- RGB amplifiers
- Test equipment amplifiers
- Current to voltage converter

General Description

The EL2260C/EL2460C are dual/quad current feedback operational amplifiers with -3 dB bandwidth of 130 MHz at a gain of +2. Built using the Elantec proprietary monolithic complementary bipolar process, these amplifiers use current mode feedback to achieve more bandwidth at a given gain than a conventional voltage feedback operational amplifier.

The EL2260C/EL2460C are designed to drive a double terminated 75 Ω coax cable to video levels. Differential gain and phase are excellent when driving both loads of 500 Ω ($<0.01\%$ / $<0.01^\circ$) and double terminated 75 Ω cables (0.025%/0.1°).

The amplifiers can operate on any supply voltage from 4V ($\pm 2V$) to 33V ($\pm 16.5V$), yet consume only 7.5 mA per amplifier at any supply voltage. Using industry standard pinouts, the EL2260C is available in 8-pin P-DIP and 8-pin SO packages, while the EL2460C is available in 14-pin P-DIP and 14-pin SO packages.

Elantec's facilities comply with MIL-I-45208A and offer applicable quality specifications. For information on Elantec's processing, see the Elantec document, QRA-1: *Elantec's Processing—Monolithic Products*.

Important Note:

All parameters having Min/Max specifications are guaranteed. The Test Level column indicates the specific device testing actually performed during production and Quality inspection. Elantec performs most electrical tests using modern high-speed automatic test equipment, specifically the LTX77 Series system. Unless otherwise noted, all tests are pulsed tests, therefore $T_J = T_C = T_A$.

Test Level	Test Procedure
I	100% production tested and QA sample tested per QA test plan QCX0002.
II	100% production tested at $T_A = 25^\circ\text{C}$ and QA sample tested at $T_A = 25^\circ\text{C}$, T_{MAX} and T_{MIN} per QA test plan QCX0002.

dG	Differential Gain (Notes 7, 8)	$R_L = 150\Omega$		0.025		V	%
		$R_L = 500\Omega$		0.006		V	%
dP	Differential Phase (Notes 7, 8)	$R_L = 150\Omega$		0.1		V	deg (°)
		$R_L = 500\Omega$		0.005		V	deg (°)

Note 1: Measured from T_{MIN} to T_{MAX} .

Note 2: $V_{CM} = \pm 10V$ for $V_S = \pm 15V$ and $T_A = Full$

$V_{CM} = \pm 3V$ for $V_S = \pm 5V$ and $T_A = 25^\circ C$

$V_{CM} = \pm 2V$ for $V_S = \pm 5V$ and $T_A = T_{MIN}, T_{MAX}$

Note 3: The supplies are moved from $\pm 2.5V$ to $\pm 15V$.

Note 4: $V_{OUT} = \pm 7V$ for $V_S = \pm 15V$, and $V_{OUT} = \pm 2V$ for $V_S = \pm 5V$.

Note 5: A heat sink is required to keep junction temperature below absolute maximum when an output is shorted.

Note 6: Slew Rate is with V_{OUT} from $+10V$ to $-10V$ and measured at the 25% and 75% points.

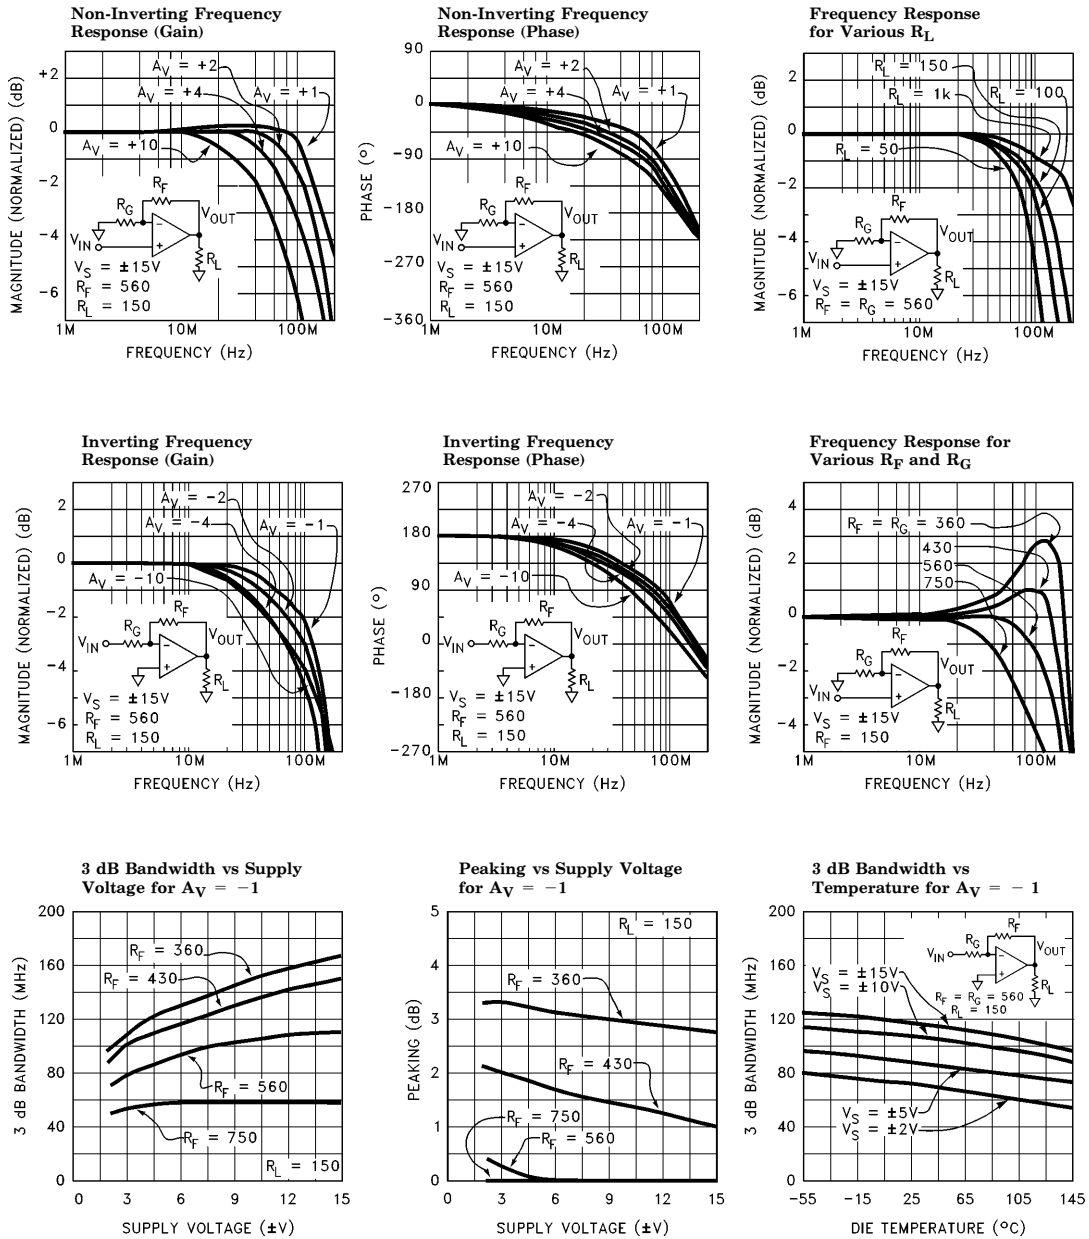

Note 7: DC offset from $-0.714V$ through $+0.714V$, AC amplitude 286 mV_{p-p}, $f = 3.58 MHz$.

Note 8: All AC tests are performed on a “warmed up” part, except for Slew Rate, which is pulse tested.

EL2260C/EL2460C

Dual/Quad 130 MHz Current Feedback Amplifiers

Applications Information

Product Description

The EL2260C/EL2460C are dual and quad current mode feedback amplifiers that offer wide bandwidths and good video specifications at moderately low supply currents. They are built using Elantec's proprietary complimentary bipolar process and are offered in industry standard pin-outs. Due to the current feedback architecture, the EL2260C/EL2460C closed-loop 3 dB bandwidth is dependent on the value of the feedback resistor. First the desired bandwidth is selected by choosing the feedback resistor, R_F , and then the gain is set by picking the gain resistor, R_G . The curves at the beginning of the Typical Performance Curves section show the effect of varying both R_F and R_G . The 3 dB bandwidth is somewhat dependent on the power supply voltage. As the supply voltage is decreased, internal junction capacitances increase, causing a reduction in closed loop bandwidth. To compensate for this, smaller values of feedback resistor can be used at lower supply voltages.

Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended. Lead lengths should be as short as possible, below $\frac{1}{4}$ ". The power supply pins must be well bypassed to reduce the risk of oscillation. A 1.0 μ F tantalum capacitor in parallel with a 0.01 μ F ceramic capacitor is adequate for each supply pin.

For good AC performance, parasitic capacitances should be kept to a minimum, especially at the inverting input (see Capacitance at the Inverting Input section). This implies keeping the ground plane away from this pin. Carbon resistors are acceptable, while use of wire-wound resistors should not be used because of their parasitic inductance. Similarly, capacitors should be low inductance for best performance. Use of sockets, particularly for the SO packages, should be avoided. Sockets add parasitic inductance and capacitance which will result in peaking and overshoot.

Capacitance at the Inverting Input

Due to the topology of the current feedback amplifier, stray capacitance at the inverting input will affect the AC and transient performance of the EL2260C/EL2460C when operating in the non-inverting configuration. The characteristic curve of gain vs. frequency with variations of C_{IN-} emphasizes this effect. The curve illustrates how the bandwidth can be extended to beyond 200 MHz with some additional peaking with an additional 2 pF of capacitance at the V_{IN-} pin for the case of $A_V = +2$. Higher values of capacitance will be required to obtain similar effects at higher gains.

In the inverting gain mode, added capacitance at the inverting input has little effect since this point is at a virtual ground and stray capacitance is therefore not "seen" by the amplifier.

Feedback Resistor Values

The EL2260C and EL2460C have been designed and specified with $R_F = 560\Omega$ for $A_V = +2$. This value of feedback resistor yields extremely flat frequency response with little to no peaking out to 130 MHz. As is the case with all current feedback amplifiers, wider bandwidth, at the expense of slight peaking, can be obtained by reducing the value of the feedback resistor. Inversely, larger values of feedback resistor will cause rolloff to occur at a lower frequency. By reducing R_F to 430 Ω , bandwidth can be extended to 170 MHz with under 1 dB of peaking. Further reduction of R_F to 360 Ω increases the bandwidth to 195 MHz with about 2.5 dB of peaking. See the curves in the Typical Performance Curves section which show 3 dB bandwidth and peaking vs. frequency for various feedback resistors and various supply voltages.

Bandwidth vs Temperature

Whereas many amplifier's supply current and consequently 3 dB bandwidth drop off at high temperature, the EL2260C/EL2460C were designed to have little supply current variations with temperature. An immediate benefit from this is that the 3 dB bandwidth does not drop off drastically with temperature. With $V_S = \pm 15V$ and $A_V = +2$, the bandwidth only varies from 150 MHz to 110 MHz over the entire die junction temperature range of $0^\circ C < T < 150^\circ C$.

EL2260C/EL2460C

Dual/Quad 130 MHz Current Feedback Amplifiers

Applications Information — Contd.

Supply Voltage Range

The EL2260C/EL2460C has been designed to operate with supply voltages from $\pm 2\text{V}$ to $\pm 15\text{V}$. Optimum bandwidth, slew rate, and video characteristics are obtained at higher supply voltages. However, at $\pm 2\text{V}$ supplies, the 3 dB bandwidth at $A_V = +2$ is a respectable 70 MHz. The following figure is an oscilloscope plot of the EL2260C at $\pm 2\text{V}$ supplies, $A_V = +2$, $R_F = R_G = 560\Omega$, driving a load of 150Ω , showing a clean $\pm 600\text{ mV}$ signal at the output.

2260-13

If a single supply is desired, values from $+4\text{V}$ to $+30\text{V}$ can be used as long as the input common mode range is not exceeded. When using a single supply, be sure to either 1) DC bias the inputs at an appropriate common mode voltage and AC couple the signal, or 2) ensure the driving signal is within the common mode range of the EL2260C/EL2460C.

Settling Characteristics

The EL2260C/EL2460C offer superb settling characteristics to 0.1%, typically in the 35 ns to 40 ns range. There are no aberrations created from the input stage which often cause longer settling times in other current feedback amplifiers. The EL2260C/EL2460C are not slew rate limited, therefore any size step up to $\pm 10\text{V}$ gives approximately the same settling time.

As can be seen from the Long Term Settling Error curve, for $A_V = +1$, there is approximately a 0.035% residual which tails away to 0.01% in about 40 μs . This is a thermal settling error

caused by a power dissipation differential (before and after the voltage step). For $A_V = -1$, due to the inverting mode configuration, this tail does not appear since the input stage does not experience the large voltage change as in the non-inverting mode. With $A_V = -1$, 0.01% settling time is slightly greater than 100 ns.

Power Dissipation

The EL2260C/EL2460C amplifiers combine both high speed and large output current drive capability at a moderate supply current in very small packages. It is possible to exceed the maximum junction temperature allowed under certain supply voltage, temperature, and loading conditions. To ensure that the EL2260C/EL2460C remain within their absolute maximum ratings, the following discussion will help to avoid exceeding the maximum junction temperature.

The maximum power dissipation allowed in a package is determined by its thermal resistance and the amount of temperature rise according to

$$P_{\text{DMAX}} = \frac{T_{\text{JMAX}} - T_{\text{AMAX}}}{\theta_{\text{JA}}}$$

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage plus the power in the IC due to the load, or

$$P_{\text{DMAX}} = N * \left(2 * V_S * I_S + (V_S - V_{\text{OUT}}) * \frac{V_{\text{OUT}}}{R_L} \right)$$

where N is the number of amplifiers per package, and I_S is the current per amplifier. (To be more accurate, the quiescent supply current flowing in the output driver transistor should be subtracted from the first term because, under loading and due to the class AB nature of the output stage, the output driver current is now included in the second term.)

In general, an amplifier's AC performance degrades at higher operating temperature and lower supply current. Unlike some amplifiers, such as the LT1229 and LT1230, the EL2260C/EL2460C

EL2260C/EL2460C

Dual/Quad 130 MHz Current Feedback Amplifiers

Applications Information — Contd.

maintain almost constant supply current over temperature so that AC performance is not degraded as much over the entire operating temperature range. Of course, this increase in performance doesn't come for free. Since the current has increased, supply voltages must be limited so that maximum power ratings are not exceeded.

Each amplifier in the EL2260C/EL2460C consume typically 7.5 mA and maximum 10.0 mA. The worst case power in an IC occurs when the output voltage is at half supply, if it can go that far, or its maximum value if it cannot reach half supply. If we assume that the EL2260C/EL2460C is used for double terminated video cable driving applications ($R_L = 150\Omega$), and the gain = +2, then the maximum output voltage is 2V, and the average output voltage is 1.4V. If we set the two P_{Dmax} equations equal to each other, and solve for V_S , we can get a family of curves for various packages and conditions according to:

$$V_S = \frac{R_L * (T_{JMAX} - T_{AMAX})}{N * \theta_{JA}} + (V_{OUT})^2 / (2 * I_S * R_L) + V_{OUT}$$

The following curve shows supply voltage ($\pm V_S$) vs. temperature for the various packages assuming $A_V = +2$, $R_L = 150$, and V_{OUT} peak = 2V. The curves include worst case conditions ($I_S = 10$ mA and all amplifiers operating at V_{OUT} peak = 2V).

Supply Voltage vs Ambient Temperature for All Packages of EL2260C/EL2460C

The curves do not include heat removal or forcing air, or the simple fact that the package will probably be attached to a circuit board, which can also provide some form of heat removal. Larger temperature and voltage ranges are possible with heat removal and forcing air past the part.

Current Limit

The EL2260C/EL2460C have internal current limits that protect the circuit in the event of the output being shorted to ground. This limit is set at 100 mA nominally and reduces with junction temperature. At a junction temperature of 150°C, the current limits at about 65 mA. If any one output is shorted to ground, the power dissipation could be well over 1W, and much greater if all outputs are shorted. Heat removal is required in order for the EL2260C/EL2460C to survive an indefinite short.

Channel to Channel Isolation

Due to careful biasing connections within the internal circuitry of the EL2260C/EL2460C, exceptionally good channel isolation is obtained. Isolation is over 70 dB at video frequencies of 4 MHz, and over 65 dB up to 10 MHz. The EL2460C isolation is improved an additional 10 dB, up to about 5 MHz, for amplifiers A to B and amplifiers C to D. Isolation is improved another 8 dB for amplifiers A to C and amplifiers B to D. See the curve in the Typical Performance Curves section for more detail.

Driving Cables and Capacitive Loads

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, the back termination series resistor will decouple the EL2260C and EL2460C from the capacitive cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without termination resistors. In these applications, an additional small value (5Ω–50Ω) resistor in series with the output will eliminate most peaking. The gain resistor, R_G , can be chosen to make up for the gain loss created by this additional series resistor at the output.
