## General Description

The **ICS9248-98** is a single chip clock solution for Desktop designs. It provides all necessary clock signals for such a system.

Spread spectrum may be enabled through I<sup>2</sup>C programming. Spread spectrum typically reduces system EMI by 8dB to 10dB. This simplifies EMI qualification without resorting to board design iterations or costly shielding. The ICS9248-98 employs a proprietary closed loop design, which tightly controls the percentage of spreading over process and temperature variations.

Serial programming I<sup>2</sup>C interface allows changing functions, stop clock programming and frequency selection.

## Power Groups

VDD1 = REF, X1, X2

### Notes:

1. The ICS clock generator is a slave/receiver, I<sup>2</sup>C component. It can read back the data stored in the latches for verification. **Read-Back will support Intel PIIX4 "Block-Read" protocol.**
2. The data transfer rate supported by this clock generator is 100K bits/sec or less (standard mode)
3. The input is operating at 3.3V logic levels.
4. The data byte format is 8 bit bytes.
5. To simplify the clock generator I<sup>2</sup>C interface, the protocol is set to use only **"Block-Writes"** from the controller. The bytes must be accessed in sequential order from lowest to highest byte with the ability to stop after any complete byte has been transferred. The Command code and Byte count shown above must be sent, but the data is ignored for those two bytes. The data is loaded until a Stop sequence is issued.
6. At power-on, all registers are set to a default condition, as shown.

## CLK\_STOP# Timing Diagram

CLK\_STOP# is an asynchronous input to the clock synthesizer. It is used to turn off the CPU clocks for low power operation. CLK\_STOP# is synchronized by the **ICS9248-98**. The minimum that the CPU clock is enabled (CLK\_STOP# high pulse) is 100 CPU clocks. All other clocks will continue to run while the CPU clocks are disabled. The CPU clocks will always be stopped in a low state and start in such a manner that guarantees the high pulse width is a full pulse. CPU clock on latency is less than 4 CPU clocks and CPU clock off latency is less than 4 CPU clocks.

### Notes:

1. All timing is referenced to the internal CPU clock.
2. CLK\_STOP# is an asynchronous input and metastable conditions may exist. This signal is synchronized to the CPU clocks inside the **ICS9248-98**.
3. IOAPIC output is Stopped Glitch Free by CLK\_STOP# going low.
4. SDRAM-F output is controlled by Buffer in signal, not affected by the **ICS9248-98** CLK\_STOP# signal. SDRAM's are controlled as shown.
5. All other clocks continue to run undisturbed.

## PCI\_STOP# Timing Diagram

PCI\_STOP# is an asynchronous input to the **ICS9248-98**. It is used to turn off the PCICLK clocks for low power operation. PCI\_STOP# is synchronized by the **ICS9248-98** internally. The minimum that the PCICLK clocks are enabled (PCI\_STOP# high pulse) is at least 10 PCICLK clocks. PCICLK clocks are stopped in a low state and started with a full high pulse width guaranteed. PCICLK clock on latency cycles are only one rising PCICLK clock off latency is one PCICLK clock.

### Notes:

1. All timing is referenced to the Internal CPUCLK (defined as inside the ICS9248-98 device.)
2. PCI\_STOP# is an asynchronous input, and metastable conditions may exist. This signal is required to be synchronized inside the ICS9248-98.
3. All other clocks continue to run undisturbed.
4. CPU\_STOP# is shown in a high (true) state.

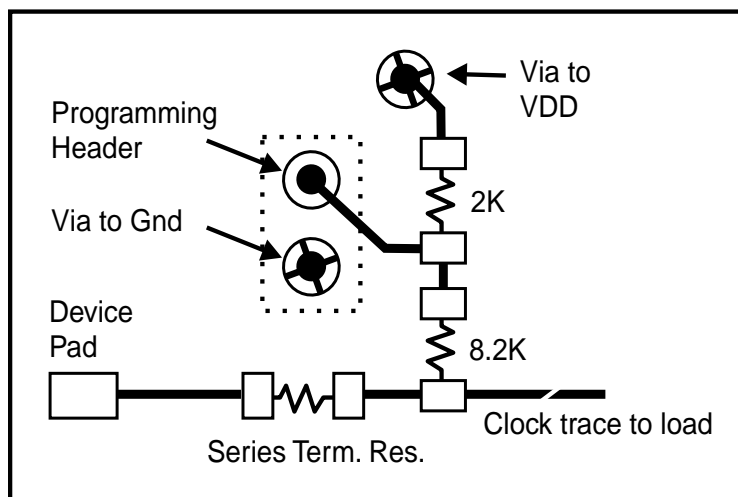

## Shared Pin Operation - Input/Output Pins

The I/O pins designated by (input/output) on the ICS9248-98 serve as dual signal functions to the device. During initial power-up, they act as input pins. The logic level (voltage) that is present on these pins at this time is read and stored into a 5-bit internal data latch. At the end of Power-On reset, (see AC characteristics for timing values), the device changes the mode of operations for these pins to an output function. In this mode the pins produce the specified buffered clocks to external loads.

To program (load) the internal configuration register for these pins, a resistor is connected to either the VDD (logic 1) power supply or the GND (logic 0) voltage potential. A 10 Kilohm (10K) resistor is used to provide both the solid CMOS programming voltage needed during the power-up programming period and to provide an insignificant load on the output clock during the subsequent operating period.

Figure 1 shows a means of implementing this function when a switch or 2 pin header is used. With no jumper is installed the pin will be pulled high. With the jumper in place the pin will be pulled low. If programmability is not necessary, than only a single resistor is necessary. The programming resistors should be located close to the series termination resistor to minimize the current loop area. It is more important to locate the series termination resistor close to the driver than the programming resistor.

## General Layout Precautions:

- 1) Use a ground plane on the top layer of the PCB in all areas not used by traces.
- 2) Make all power traces and vias as wide as possible to lower inductance.

## Notes:

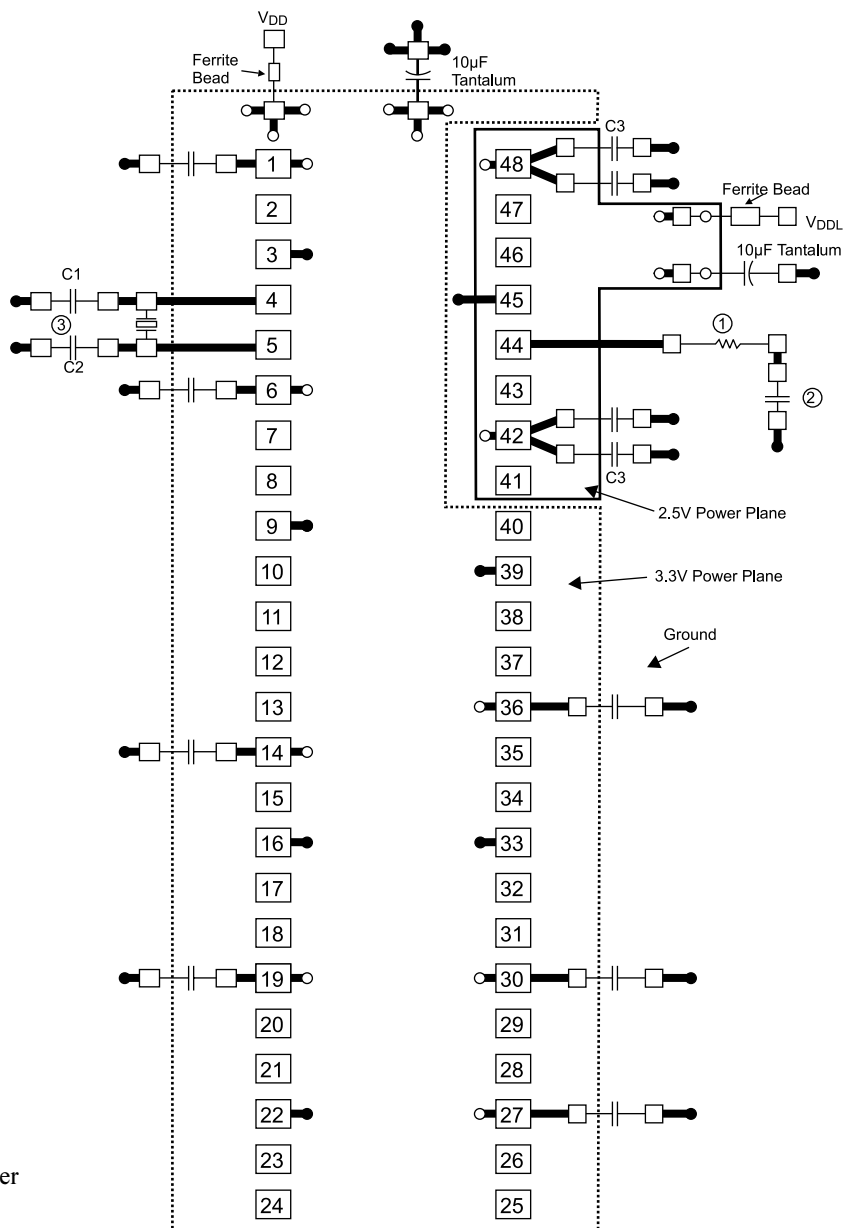

- 1 All clock outputs should have series terminating resistor. Not shown in all places to improve readability of diagram
- 2 Optional EMI capacitor should be used on all CPU, SDRAM, and PCI outputs.
- 3 Optional crystal load capacitors are recommended.

## Capacitor Values:

C1, C2 : Crystal load values determined by user

C3 : 100pF ceramic

All unmarked capacitors are 0.01μF ceramic
