

## FEATURES

- Pin Compatible with LH0070 and AD581\*
- Ultra Low Drift—5ppm/°C Max Slope
- Trimmed Output Voltage
- Operates in Series or Shunt Mode
- Output Sinks and Sources in Series Mode
- Very Low Noise < 1ppm p-p 0.1Hz to 10Hz
- > 100dB Ripple Rejection
- Minimum Input Voltage of 11V

## APPLICATIONS

- A to D and D to A Converters
- Precision Regulators
- Digital Voltmeters
- Inertial Navigation Systems
- Precision Scales
- Portable Reference Standard

\*See LH0070 Electrical Characteristics table and AD581 cross reference guide.

## DESCRIPTION

The LT1031 is a precision 10V reference with ultra low drift and noise, extremely good long term stability, and almost total immunity to input voltage variations. The reference output will both source and sink up to 10mA and can be used as a shunt regulator (two terminal zener) with the same precision characteristics as the three terminal connection. Special care has been taken to minimize thermal regulation effects and temperature induced hysteresis.

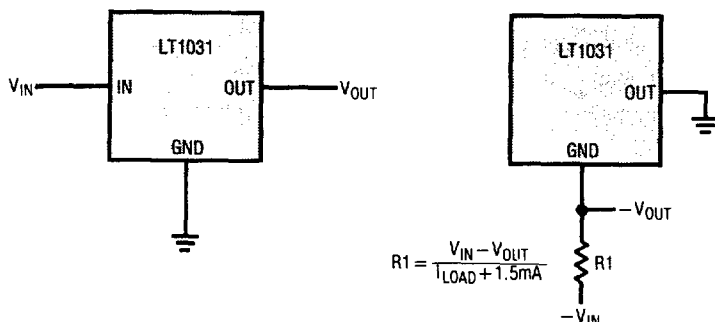

The LT1031 reference is based on a buried zener diode structure which eliminates noise and stability problems associated with surface breakdown devices. Further, a subsurface zener exhibits better temperature drift and time stability than even the best band-gap references.

Unique circuit design makes the LT1031 the first three terminal IC reference to offer ultra low drift without the use of high power on-chip heaters. Output voltage is pre-trimmed to 0.05% accuracy.

The LT1031 can be used as a plug-in replacement for the AD581 and LH0070\*, with improved electrical and thermal performance.

The ● denotes the specifications which apply over the full operating temperature range.

**Note 1:** Output voltage is measured immediately after turn-on. Changes due to chip warm-up are typically less than 0.005%.

**Note 2:** Temperature coefficient is measured by dividing the change in output voltage over the temperature range by the change in temperature. Separate tests are done for hot and cold;  $T_{MIN}$  to  $25^\circ C$ , and  $25^\circ C$  to  $T_{MAX}$ . **Incremental slope is also measured at  $25^\circ C$ .** For LT1031BMH, the 5ppm/ $^\circ C$  drift specification is for  $-25^\circ C$  to  $85^\circ C$ . Drift over the full  $-55^\circ C$  to  $+125^\circ C$  range is guaranteed to 7ppm/ $^\circ C$ .

**Note 3:** Line and load regulation are measured on a pulse basis. Output changes due to die temperature change must be taken into account separately. Package thermal resistance is  $150^\circ C/W$ .

**Note 4:** Shunt mode regulation is measured with the input open. With the input connected, shunt mode current can be reduced to 0mA. Load regulation will remain the same.

**Note 5:** Temperature drift is guaranteed from  $-25^\circ C$  to  $+85^\circ C$  on LH0070.

**Note 6:** See curve for guaranteed minimum  $V_{IN}$  versus  $I_{OUT}$ .

**Note 7:** Guaranteed by design.

## CROSS REFERENCE

The following cross reference guide may be used to select LT1031 grades which meet or exceed output voltage, temperature drift, load and line regulation, and output current specifications of the AD581 reference. Parameters such as noise, hysteresis, and long term stability will be significantly better for all LT1031 grades compared to the AD581.

## APPLICATIONS INFORMATION

### Trimming Output Voltage

The LT1031 output can be trimmed by driving the ground pin. The suggested method is shown in the accompanying figure. A  $5\Omega$  resistor is inserted in series with the ground pin and the top of the resistor is supplied current from a trim potentiometer. This technique requires fairly high trim current—up to 1.5mA from the LT1031 or 3.5mA from the  $-15\text{V}$  supply, but it is necessary to maintain low drift in the reference. Ground pin current changes in the LT1031 (with temperature) could be as high as  $4\mu\text{A}/^\circ\text{C}$ . This, coupled with the  $5\Omega$  external resistor, creates up to  $2\text{ppm}/^\circ\text{C}$  drift in the reference ( $5\Omega \times 4\mu\text{A}/^\circ\text{C} = 20\mu\text{V}/^\circ\text{C} = 2\text{ppm}/^\circ\text{C}$ ). If induced drift higher than this can be tolerated, all resistor values in the trim circuit can be raised proportionately to reduce current drain.

### Effect of Reference Drift on System Accuracy

A large portion of the temperature drift error budget in many systems is the system reference voltage. This graph indicates the maximum temperature coefficient allowable if the reference is to contribute no more than  $\frac{1}{2}\text{LSB}$  error to the overall system performance. The example shown is a 12-bit system designed to operate over a temperature range from  $25^\circ\text{C}$  to  $65^\circ\text{C}$ . Assuming the system calibration is performed at  $25^\circ\text{C}$ , the temperature span is  $40^\circ\text{C}$ . It can be seen from the graph that the temperature coefficient of the reference must be no worse than  $3\text{ppm}/^\circ\text{C}$  if it is to contribute less than  $\frac{1}{2}\text{LSB}$  error. For this reason, the LT1031 has been optimized for low drift.

### Maximum Allowable Reference Drift

### Capacitive Loading and Transient Response

The LT1031 is stable with all capacitive loads, but for optimum settling with load transients, output capacitance should be under 1000pF. The output stage of the reference is class AB with a fairly low idling current. This makes transient response worst-case at light load currents. Because of internal current drain on the output, actual worst-case occurs at  $I_{\text{LOAD}} = 1.4\text{mA}$  (sinking). Significantly better load transient response is obtained by moving slightly away from these points. See Load Transient Response curves for details. In general, best transient response is obtained when the output is sourcing current. In critical applications, a  $10\mu\text{F}$  solid tantalum capacitor with several ohms in series provides optimum output bypass.

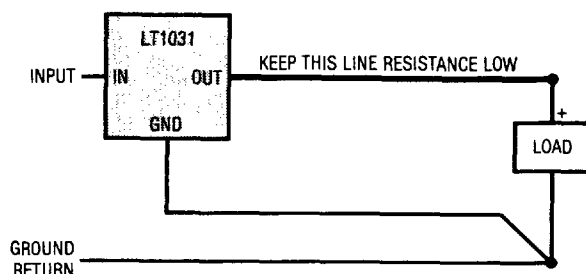

### Kelvin Connections

Although the LT1031 does not have true force/sense capability at its outputs, significant improvements in ground loop and line loss problems can be achieved with proper hook-up. In series mode operation, the ground pin of the LT1031 carries only  $\approx 1\text{mA}$  and can be used as a sense line, greatly reducing ground loop and loss problems on the low side of the reference. The high side supplies load current so line resistance must be kept low. Twelve feet of #22 gauge hook up wire or 1 foot of 0.025 inch printed circuit trace will create 2mV loss at 10mA output current. This is equivalent to 1LSB in a 10V, 12-bit system.

## APPLICATIONS INFORMATION

The circuits below show proper hook up to minimize errors due to ground loops and line losses. Losses in the output lead can be greatly reduced by adding a PNP boost transistor if load currents are 5mA or higher. R2 can be added to further reduce current in the output sense lead.

\*OPTIONAL—REDUCES CURRENT IN OUTPUT SENSE LEAD

### Effects of Air Movement on Low Frequency Noise

The LT1031 has very low noise because of the buried zener used in its design. In the 0.1Hz to 10Hz band, peak-to-peak noise is about 0.5ppm of the DC output. To achieve this low noise, however, care must be taken to shield the reference from ambient air turbulence. Air

movement can create noise because of thermoelectric differences between IC package leads (especially kovar lead TO-5) and printed circuit board materials and/or sockets. Power dissipation in the reference, even though it rarely exceeds 20mW, is enough to cause small temperature gradients in the package leads. Variations in thermal resistance, caused by uneven air flow, create differential lead temperatures, thereby causing thermoelectric voltage noise at the output of the reference. The XY plotter trace shown below dramatically illustrates this effect. The first half of the plot was done with the LT1031 shielded from ambient air with a small foam cup. The cup was then removed for the second half of the trace. Ambient in both cases was a lab environment with no excessive air turbulence from air conditioners, opening/closing doors, etc. Removing the foam cup increases the output noise by almost an order of magnitude in the 0.01Hz to 1Hz band! The kovar leads of the TO-5 (H) package are the primary culprit. Alloy 42 and copper lead frames used on dual-in-line packages are not nearly as sensitive to thermally generated noise because they are intrinsically matched.

There is nothing magical about foam cups—any enclosure which blocks air flow from the reference will do. Smaller enclosures are better since they do not allow the build-up of internally generated air movement. Naturally, heat generating components external to the reference itself should not be included inside the enclosure.

Diagram illustrating the LT1031 in a voltage follower configuration. The input (IN) is connected to a +15V supply through a 30mA current source. The output (OUT) is connected to a load resistor  $R_L$  and a feedback resistor  $R1^*$  (169Ω) which is connected back to the input. The output voltage  $V_{OUT}$  is 10V. A typical load current of 30mA is indicated.

3

The circuit diagram illustrates a precision instrumentation amplifier configuration. It begins with a +15V supply connected to the IN pin of an LT1031 precision current source. A resistor R1 (357Ω, 1/2W) is connected between the +15V supply and the OUT pin of the LT1031. The OUT pin is connected to a 5V supply, with a current of 28mA flowing into it and 28.5mA flowing out. The 5V supply is connected to the top of a 350Ω strain gauge bridge. The bottom of the bridge is connected to a -5V supply, which is also connected to the GND pin of the LT1031. The strain gauge bridge is represented by four resistors in a Wheatstone bridge configuration. The output of the bridge is connected to the non-inverting input (pin 2) of an LM301A operational amplifier. The LM301A is configured with its non-inverting input (pin 2) connected to the bridge output, its inverting input (pin 1) connected to the -5V supply, and its output (pin 3) connected to the non-inverting input (pin 2). A 100pF capacitor is connected between pins 1 and 8 of the LM301A. The output of the LM301A is connected to the non-inverting input (pin 2) of an LT1012C operational amplifier. The LT1012C is configured with its non-inverting input (pin 2) connected to the LM301A output, its inverting input (pin 3) connected to the -5V supply, and its output (pin 6) connected to the non-inverting input (pin 2). A 2MΩ resistor (R3) is connected between the output (pin 6) and the inverting input (pin 3) of the LT1012C. A 20kΩ resistor (R2) is connected between the output (pin 6) and the non-inverting input (pin 2) of the LT1012C. A 20kΩ resistor (R4) is connected between the output (pin 6) and the inverting input (pin 3) of the LT1012C. A 2MΩ resistor (R5) is connected between the output (pin 6) and the non-inverting input (pin 2) of the LT1012C. A 2MΩ resistor (R6) is connected between the output (pin 6) and the inverting input (pin 3) of the LT1012C. The final output of the circuit is VOUT X100, which is connected to the output (pin 6) of the LT1012C. The circuit is powered by a +15V supply and a -15V supply, with a 357Ω, 1/2W resistor connected between the -15V supply and the -5V supply.
