

FEATURES

- Differential or Single-Ended Gain Block (Adjustable)
- -3dB Bandwidth, $A_V = \pm 2$ 80MHz
- Slew Rate 500V/ μ s
- Low Cost
- Output Current ± 50 mA
- Settling Time 180ns to 0.1%
- CMRR @ 10MHz >40dB
- Differential Gain Error 0.2%
- Differential Phase Error 0.08°
- Single +5V Operation
- Drives Cables Directly
- Output Shutdown

APPLICATIONS

- Line Receivers
- Video Signal Processing
- Cable Drivers
- Oscillators
- Tape and Disc Drive Systems

DESCRIPTION

The LT1193 is a video difference amplifier optimized for operation on ± 5 V, and a single +5V supply. This versatile amplifier features uncommitted high input impedance (+) and (-) inputs, and can be used in differential or single-ended configurations. Additionally, a second set of inputs give gain adjustment and DC control to the differential amplifier.

The LT1193's high slew rate, 500V/ μ s, wide bandwidth, 80MHz, and ± 50 mA output current, make it ideal for driving cables directly. The shutdown feature reduces the power dissipation to a mere 15mW, and allows multiple amplifiers to drive the same cable.

The LT1193 is available in 8-pin miniDIPs and SO packages.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: A heat sink is required to keep the junction temperature below absolute maximum when the output is shorted.

Note 2: When $R_L = 1k$ is specified, the load resistor is $R_{FB1} + R_{FB2}$, but when $R_L = 100\Omega$ is specified, then an additional 100Ω is added to the output.

Note 3: V_{OS} measured at the output (pin 6) is the contribution from both input pair, and is input referred.

Note 4: V_{IN_LIM} is the maximum voltage between $-V_{IN}$ and $+V_{IN}$ (pin 2 and pin 3) for which the output can respond.

Note 5: Slew rate is measured between $\pm 2V$ on the output, with a $\pm 1V$ input step, $A_V = +3$.

Note 6: Full power bandwidth is calculated from the slew rate measurement: $FPBW = SR/2\pi V_p$.

Note 7: Settling time measurement techniques are shown in "Take the Guesswork Out of Settling Time Measurements," EDN, September 19, 1985.

Note 8: NTSC (3.58MHz).

Note 9: See Applications section for shutdown at elevated temperatures. Do not operate the shutdown above $T_J > 125^\circ C$.

Note 10: AC parameters are 100% tested on the ceramic and plastic DIP packaged parts (J and N suffix) and are sample tested on every lot of the SO packaged parts (S suffix).

LT1193 - TPC24

APPLICATIONS INFORMATION

The LT1193 is a video difference amplifier which has two uncommitted high input impedance (+) and (–) inputs. The amplifier has one set of inputs which can be used for reference and feedback. Additionally, this set of inputs give gain adjust, and DC control to the differential amplifier. The voltage gain of the LT1193 is set like a conventional operational amplifier. Feedback is applied to pin 8, and it is optimized for gains of 2 or greater. The amplifier can be operated single-ended by connecting either the (+) or (–) inputs to the +/Reference pin 1. The voltage gain is set by the resistors: $(R_{FB} + R_G)/R_G$.

The primary usefulness of the LT1193 is in converting high speed differential signals to a single-ended output. The amplifier has common mode rejection beyond 50MHz, and a full power bandwidth of 40MHz at 4Vp-p. Like the single-ended case, the differential voltage gain is set by the external resistors: $(R_{FB} + R_G)/R_G$. The maximum input differential signal for which the output will respond is approximately $\pm 1.3V$.

Power Supply Bypassing

The LT1193 is quite tolerant of power supply bypassing. In some applications a 0.1μF ceramic disc capacitor placed 1/2 inch from the amplifier is all that is required. A scope photo of the amplifier output with no supply bypassing is used to demonstrate this bypassing tolerance, $R_L = 1k\Omega$.

No Supply Bypass Capacitors

$A_V = +10$, IN DEMO BOARD, $R_L = 1k\Omega$

LT1193 - TA04

In many applications and those requiring good settling time it is important to use multiple bypass capacitors. A 0.1μF ceramic disc in parallel with a 4.7μF tantalum is recommended. Two oscilloscope photos with different bypass conditions are used to illustrate the settling time characteristics of the amplifier. Note that although the output waveform looks acceptable at 1V/div, when

Settling Time Poor Bypass

SETTLING TIME TO 10mV, $A_V = 2$

LT1193 - TA05

APPLICATIONS INFORMATION

Settling Time Good Bypass

SETTLING TIME TO 10mV, $A_V = 2$
SUPPLY BYPASS CAPACITORS = $0.1\mu\text{F} + 4.7\mu\text{F}$ TANTALUM

LT1193 - TA06

amplified to 10mV/div the settling time to 10mV is 347ns for the $0.1\mu\text{F}$ bypass; the time drops to 96ns with multiple bypass capacitors.

Operating With Low Closed Loop Gains

The LT1193 has been optimized for closed loop gains of 2 or greater; the frequency response illustrates the obtainable closed loop bandwidths. For a closed loop gain of 2 the response peaks about +2dB. Peaking can be minimized by keeping the feedback elements below $1\text{k}\Omega$, and can be eliminated by placing a capacitor across the feedback resistor, (feedback zero). This peaking shows up as time domain overshoot of about 40%. With the feedback capacitor it is eliminated.

RISE TIME = 3.75ns, $R_{FB} = 1\text{k}$, $R_G = 1\text{k}$

LT1193 - TA10

APPLICATIONS INFORMATION

Cable Terminations

The LT1193 video difference amplifier has been optimized as a low cost cable driver. The $\pm 50\text{mA}$ guaranteed output current enables the LT1193 to easily deliver 7.5Vp-p into 100Ω , while operating on $\pm 5\text{V}$ supplies, and gains >3 . On a single 5V supply the LT1193 can swing 2.6Vp-p for gains ≥ 2 .

When driving a cable it is important to terminate the cable to avoid unwanted reflections. This can be done in one of two ways: single termination or double termination. With single termination, the cable must be terminated at the receiving end (75Ω to ground) to absorb unwanted energy. The best performance can be obtained by double termination (75Ω in series with the output of the amplifier, and 75Ω to ground at the other end of the cable). This termination is preferred because reflected energy is absorbed at each end of the cable. When using the double termination technique it is important to note that the signal is attenuated by a factor of 2, or 6dB. The cable driver has a -3dB bandwidth of 80MHz while driving a 150Ω load.

Double Terminated Cable Driver

Closed Loop Voltage Gain vs Frequency

Using the Shutdown Feature

The LT1193 has a unique feature that allows the amplifier to be shutdown for conserving power, or for multiplexing several amplifiers onto a common cable. The amplifier will shutdown by taking pin 5 to V^- . In shutdown, the amplifier dissipates 15mW while maintaining a true high impedance output state of $15\text{k}\Omega$ in parallel with the feedback resistors. The amplifiers may be connected inverting, non-inverting or differential for MUX applications. When the output is loaded with as little as $1\text{k}\Omega$ from the amplifier's feedback resistors, the amplifier shuts off in 200ns . This shutoff can be under the control of HC CMOS operating between 0V and -5V .

Output Shutdown

1MHz SINE WAVE GATED OFF WITH SHUTDOWN PIN.
 $A_V = +3$, $R_{FB} = 1\text{k}\Omega$, $R_G = 500\Omega$

LT1193 - TA12

The ability to maintain shutoff is shown on the curve Shutdown Supply Current vs Temperature in the Typical Performance Characteristics section. At very high elevated temperatures it is important to hold the shutdown pin close to the negative supply to keep the supply current from increasing.

APPLICATIONS INFORMATION

Murphy Circuits

There are several precautions the user should take when using the LT1193 in order to realize its full capability. Although the LT1193 can drive a 30pF in gains as low as 2, isolating the capacitance with 10 Ω can be helpful. Precautions primarily have to do with driving large capacitive loads.

Other precautions include:

1. Use a ground plane (see Design Note 50, High Frequency Amplifier Evaluation Board).

2. Do not use high source impedances. The input capacitance of 2pF, and $R_S = 10k\Omega$ for instance, will give an 8MHz -3dB bandwidth.

3. PC board socket may reduce stability.

4. A feedback resistor of 1k Ω or lower reduces the effects of stray capacitance at the inverting input. (For instance, closed loop gain of ± 2 can use $R_{FB} = 300\Omega$ and $R_G = 300\Omega$.)

Driving Capacitive Load
