

Micropower Quad 10-Bit DAC

January 2000

FEATURES

- **Tiny: 4 DACs in the Board Space of an SO-8**
- **Micropower: 59 μ A per DAC Plus
1 μ A Sleep Mode for Extended Battery Life**
- **Wide 2.7V to 5.5V Supply Range**
- **Rail-to-Rail Voltage Outputs Drive 1000pF**
- **Reference Range Includes Supply for Ratiometric
0V-to- V_{CC} Output**
- **Reference Input Has Constant Impedance over All
Codes—Eliminates External Reference Buffer**
- **Individually Addressable DACs**
- **Differential Nonlinearity: $\leq \pm 0.75$ LSB Max**
- **Pin-Compatible Octal Version Available (LTC1660)**

APPLICATIONS

- Mobile Communications
- Remote Industrial Devices
- Automatic Calibration for Manufacturing
- Portable Battery-Powered Instruments
- Trim/Adjust Applications

DESCRIPTION

The LTC®1664 integrates four accurate, serially addressable 10-bit digital-to-analog converters (DACs) in a tiny 16-pin Narrow SSOP package. Each buffered DAC draws just 59µA total supply current, yet is capable of supplying DC output currents in excess of 5mA and reliably driving capacitive loads of up to 1000pF. Sleep mode further reduces total supply current to 1µA.

Linear Technology's proprietary, inherently monotonic voltage interpolation architecture provides excellent linearity while allowing for an exceptionally small external form factor.

Ultralow supply current, power-saving Sleep mode and extremely compact size make the LTC1664 ideal for battery-powered applications, while its ease of use, high performance and wide supply range make it an excellent choice as a general purpose converter.

 LTC and LT are registered trademarks of Linear Technology Corporation.

Note 1: Absolute maximum ratings are those values beyond which the life of a device may be impaired.

Note 2: Nonlinearity and monotonicity are defined from code 20 to code 1023. See Applications Information.

Note 3: Digital inputs at 0V or V_{CC} .

Note 4: Load is $10\text{k}\Omega$ in parallel with 100pF .

Note 5: $V_{\text{CC}} = V_{\text{REF}} = 5\text{V}$. DAC switched between $0.1V_{\text{FS}}$ and $0.9V_{\text{FS}}$, i.e., codes 102 and 922.

Note 6: Guaranteed by design and not subject to test.

Note 7: Measured at code 20.

PIN FUNCTIONS

GND (Pin 1): System Ground.

V_{OUTA} to V_{OUTD} (Pins 2–5): DAC Analog Voltage Outputs. The output range is

$$0 \text{ to } \left(\frac{1023}{1024} \right) V_{\text{REF}}$$

REF (Pin 6): Reference Voltage Input. $0V \leq V_{\text{REF}} \leq V_{\text{CC}}$.

$\overline{\text{CS/LD}}$ (Pin 7): Serial Interface Chip Select/Load Input. When $\overline{\text{CS/LD}}$ is low, SCK is enabled for shifting data on D_{IN} into the register. When $\overline{\text{CS/LD}}$ is pulled high, SCK is disabled and data is loaded from the shift register into the specified DAC register(s), updating the analog output(s). CMOS and TTL compatible.

SCK (Pin 8): Serial Interface Clock Input. CMOS and TTL compatible.

D_{IN} (Pin 9): Serial Interface Data Input. Data on the D_{IN} pin is shifted into the 16-bit register on the rising edge of SCK. CMOS and TTL compatible.

D_{OUT} (Pin 10): Serial Interface Data Output. Data appears on D_{OUT} 16 positive SCK edges after being applied to D_{IN}. May be tied to D_{IN} of another serial device for daisy-chain operation. CMOS and TTL compatible.

$\overline{\text{CLR}}$ (Pin 11): Asynchronous Clear Input. All internal shift and DAC registers are cleared to zero at the falling edge of the $\overline{\text{CLR}}$ signal, forcing the analog outputs to zero scale. CMOS and TTL compatible.

NC (Pins 12–15): Make no electrical connection to these pins.

V_{CC} (Pin 16): Supply Voltage Input. $2.7V \leq V_{\text{CC}} \leq 5.5V$.

BLOCK DIAGRAM

TIMING DIAGRAM

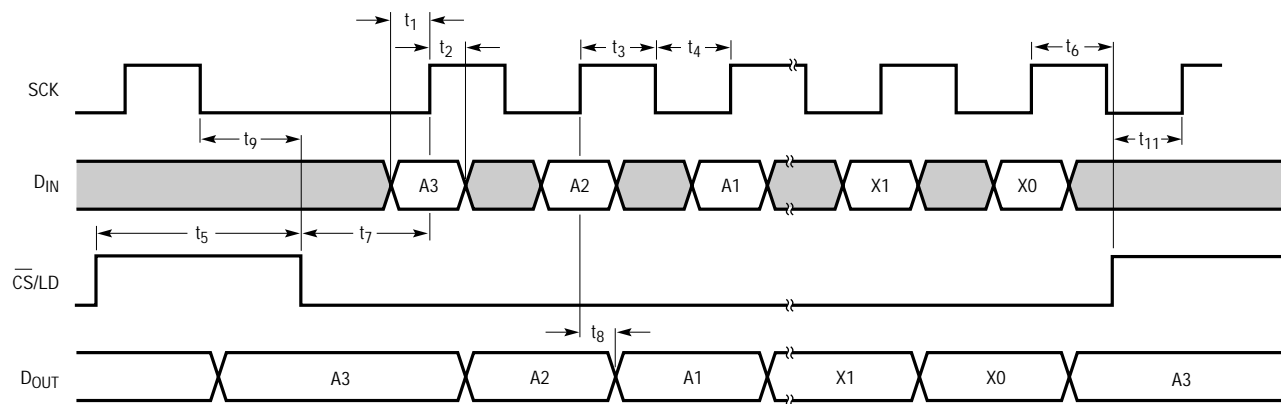

Figure 1

1664 F01

OPERATION

Transfer Function

The transfer function is

$$V_{\text{OUT(IDEAL)}} = \left(\frac{k}{1024} \right) V_{\text{REF}}$$

where k is the decimal equivalent of the binary DAC input code and V_{REF} is the voltage at REF (Pin 6).

Power-On Reset

The LTC1664 clears the outputs to zero scale when power is first applied, making system initialization consistent and repeatable.

Power Supply Sequencing

The voltage at REF (Pin 6) should be kept within the range $-0.2\text{V} \leq V_{\text{REF}} \leq V_{\text{CC}} + 0.2\text{V}$ (see Absolute Maximum Ratings). Particular care should be taken to observe these limits during power supply turn-on and turn-off sequences, when the voltage at V_{CC} (Pin 16) is in transition.

Serial Interface

Referring to Figure 2: With $\overline{\text{CS/LD}}$ held low, data on the D_{IN} input is shifted into the 16-bit shift register on the positive edge of SCK. The 4-bit DAC address, A3-A0, is loaded first (see Table 2), then the 10-bit input code, D9-D0, ordered MSB-to-LSB in each case. Two don't-care bits, X1-X0, are loaded last. When the full 16-bit input word has been shifted in, $\overline{\text{CS/LD}}$ is pulled high, loading the DAC register with the word and causing the addressed DAC output(s) to update. The clock is disabled internally when $\overline{\text{CS/LD}}$ is high. Note: SCK must be low before $\overline{\text{CS/LD}}$ is pulled low.

The buffered serial output of the shift register is available on the D_{OUT} pin, which swings from GND to V_{CC} . Data appears on D_{OUT} 16 positive SCK edges after being applied to D_{IN} .

Multiple LTC1664's can be controlled from a single 3-wire serial port (i.e., SCK, D_{IN} and $\overline{\text{CS/LD}}$) by using the included "daisy-chain" facility. A series of m chips is configured by connecting each D_{OUT} (except the last) to D_{IN} of the next chip, forming a single $16m$ -bit shift register. The SCK and $\overline{\text{CS/LD}}$ signals are common to all chips in the chain. In use, $\overline{\text{CS/LD}}$ is held low while m 16-bit words are clocked to D_{IN} of the first chip; $\overline{\text{CS/LD}}$ is then pulled high, updating all of them simultaneously.

Sleep Mode

DAC address 1110_{b} is reserved for the special Sleep instruction (see Table 2). In this mode, the digital interface stays active while the analog circuits are disabled; static power consumption is thus virtually eliminated. The reference input and analog outputs are set in a high impedance state and all DAC settings are retained in memory so that when Sleep mode is exited, the outputs of DACs not updated by the Wake command are restored to their last active state.

Sleep mode is initiated by performing a load sequence to address 1110_{b} (the DAC input word D9-D0 is ignored). Once in Sleep mode, a load sequence to any other address (including "No Change" addresses 0000_{b} and 1001 - 1101_{b}) causes the LTC1664 to Wake. It is possible to keep one or more chips of a daisy chain in continuous Sleep mode by giving the Sleep instruction to these chips each time the active chips in the chain are updated.

OPERATION

Voltage Outputs

Each of the four rail-to-rail output amplifiers contained in these parts can source or sink up to 5mA. The outputs swing to within a few millivolts of either supply rail when unloaded and have an equivalent output resistance of 85Ω when driving a load to the rails. The output amplifiers are stable driving capacitive loads up to 1000pF.

A small resistor placed in series with the output can be used to achieve stability for any load capacitance. A $1\mu\text{F}$ load can be successfully driven by inserting a 20Ω resistor; a $2.2\mu\text{F}$ load needs only a 10Ω resistor. In either case, larger values of resistance, capacitance or both may be safely substituted for the values given.

Rail-to-Rail Output Considerations

In any rail-to-rail voltage output DAC, the output is limited to voltages within the supply range.

If the DAC offset is negative, the output for the lowest codes limits at 0V as shown in Figure 3b.

Similarly, limiting can occur near full scale when the REF pin is tied to V_{CC} . If $V_{REF} = V_{CC}$ and the DAC full-scale error (FSE) is positive, the output for the highest codes limits at V_{CC} as shown in Figure 3c. No full-scale limiting can occur if V_{REF} is less than $V_{CC} - \text{FSE}$.

Offset and linearity are defined and tested over the region of the DAC transfer function where no output limiting can occur.

OPERATION

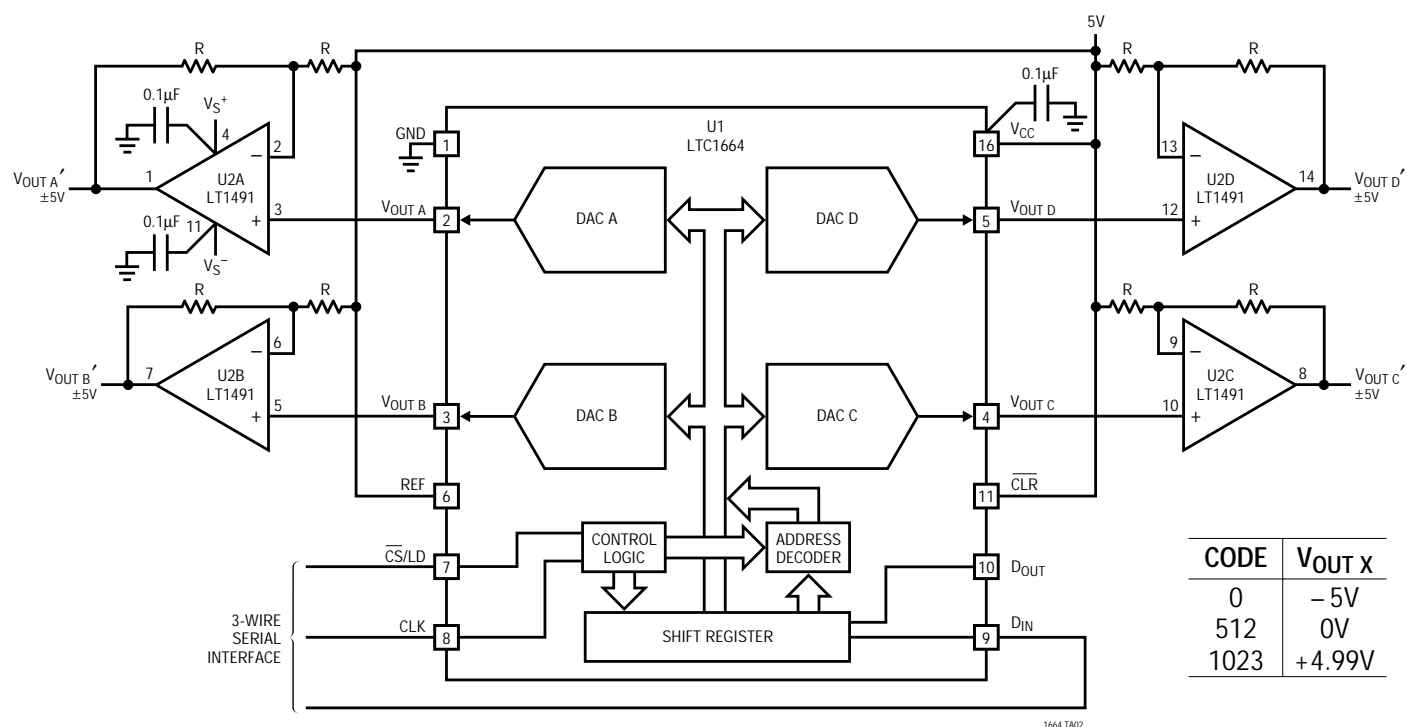

1665/60 F03

Figure 3. Effects of Rail-to-Rail Operation On a DAC Transfer Curve. (a) Overall Transfer Function (b) Effect of Negative Offset for Codes Near Zero Scale (c) Effect of Positive Full-Scale Error for Input Codes Near Full Scale When $V_{REF} = V_{CC}$

Example: For $R1 = 110\Omega$ and $R2 = 11k$,
 $V_{OUT1} = V_{OUTA} + 0.01 V_{OUTB}$
