

Negative Voltage Hot Swap Controllers in SOT-23

FEATURES

- Allows Safe Board Insertion and Removal from a Live –48V Backplane
- Floating Topology Permits Very High Voltage Operation
- Low Profile (1mm) ThinSOT™ Package
- Programmable Analog Current Limit with Circuit Breaker Timer
- Fast Response Time Limits Peak Fault Current
- Programmable Timer
- Programmable Undervoltage/Overvoltage Protection

APPLICATIONS

- Hot Board Insertion
- Electronic Circuit Breaker
- –48V Distributed Power Systems
- Negative Power Supply Control
- Central Office Switching
- Programmable Current Limiting Circuit
- High Availability Servers
- Disk Arrays

DESCRIPTION

The LTC®4251/LTC4251-1/LTC4251-2 negative voltage Hot Swap™ controllers allow a board to be safely inserted and removed from a live backplane. Output current is controlled by three stages of current limiting: a timed circuit breaker, active current limiting and a fast feedforward path that limits peak current under worst-case catastrophic fault conditions.

Programmable undervoltage and overvoltage detectors disconnect the load whenever the input supply exceeds the desired operating range. The supply input is shunt regulated, allowing safe operation with very high supply voltages. A multifunction timer delays initial start-up and controls the circuit breaker's response time.

The LTC4251 UV/OV thresholds are designed to match the standard telecom operating range of –43V to –75V. The LTC4251-1 UV/OV thresholds extend the operating range to encompass –36V to –72V. The LTC4251-2 implements a UV threshold of –43V only.

All parts are available in the 6-Pin SOT-23 package.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.
ThinSOT and Hot Swap are trademarks of Linear Technology Corporation.

PIN FUNCTIONS

UV/OV refers to the UV pin for the LTC4251-2. The OV comparator in the LTC4251-2 is disabled. All references in the text to overvoltage, OV, V_{OVHI} and V_{OVLO} do not apply to the LTC4251-2.

SENSE (Pin 1): Circuit Breaker/Current Limit SENSE Pin. Load current is monitored by sense resistor R_S connected between SENSE and V_{EE} , and controlled in three steps. If SENSE exceeds V_{CB} (50mV), the circuit breaker comparator activates a 230 μ A TIMER pin pull-up current. The LTC4251/LTC4251-1/LTC4251-2 latch off when C_T charges to 4V. If SENSE exceeds V_{ACL} (100mV), the analog current limit amplifier pulls GATE down and regulates the MOSFET current at V_{ACL}/R_S . In the event of a catastrophic short-circuit, SENSE may overshoot 100mV. If SENSE reaches V_{FCL} (200mV), the fast current limit comparator pulls GATE low with a strong pull-down. To disable the circuit breaker and current limit functions, connect SENSE to V_{EE} .

Kelvin-sense connections between the sense resistor and the V_{EE} and SENSE pins are strongly recommended, see Figure 6.

V_{EE} (Pin 2): Negative Supply Voltage Input. Connect this pin to the negative side of the power supply.

V_{IN} (Pin 3): Positive Supply Input. Connect this pin to the positive side of the supply through a dropping resistor. A shunt regulator typically clamps V_{IN} at 13V. An internal undervoltage lockout (UVLO) circuit holds GATE low until the V_{IN} pin is greater than V_{LKO} (9.2V), overriding UV/OV. If UV is high, OV is low and V_{IN} comes out of UVLO, TIMER starts an initial timing cycle before initiating a GATE ramp up. If V_{IN} drops below approximately 8.2V, GATE pulls low immediately.

TIMER (Pin 4): Timer Input. TIMER is used to generate a delay at start up, and to delay shutdown in the event of an output overload. TIMER starts an initial timing cycle when the following conditions are met: UV is high, OV is low, V_{IN} clears UVLO, TIMER pin is low, GATE is lower than V_{GATEL} and $V_{SENSE} - V_{EE} < V_{CB}$. A pull-up current of 5.8 μ A then charges C_T , generating a time delay. If C_T charges to V_{TMRH} (4V) the timing cycle terminates, TIMER quickly pulls low and GATE is activated.

If SENSE exceeds 50mV while GATE is high, a 230 μ A pull-up current charges C_T . If SENSE drops below 50mV before TIMER reaches 4V, a 5.8 μ A pull-down current slowly discharges C_T . In the event that C_T eventually integrates up to the 4V V_{TMRH} threshold, TIMER latches high with a 5.8 μ A pull-up source and GATE quickly pulls low. The LTC4251/LTC4251-1/LTC4251-2 fault latches may be cleared by either pulling TIMER low with an external device, or by pulling UV/OV below V_{UVLO} .

UV/OV (Pin 5): Undervoltage/Overvoltage Input. This dual function pin detects undervoltage as well as overvoltage. The high threshold at the UV comparator is set at V_{UVHI} with V_{UVHST} hysteresis. The high threshold at the OV comparator is set at V_{OVHI} with V_{OVHST} hysteresis. If $UV/OV < V_{UVLO}$ or $UV/OV > V_{OVHI}$, GATE pulls low. If $UV/OV > V_{UVHI}$ and $UV/OV < V_{OVLO}$, the LTC4251/LTC4251-1/LTC4251-2 attempt to start-up. The internal UVLO at V_{IN} always overrides UV/OV. A low at UV resets an internal fault latch. A high at OV pulls GATE low but does not reset the fault latch. A 1nF to 10nF capacitor at UV/OV eliminates transients and switching noise from affecting the UV/OV thresholds and prevents glitches at the GATE pin.

GATE (Pin 6): N-Channel MOSFET Gate Drive Output. This pin is pulled high by a 58 μ A current source. GATE is pulled low by invalid conditions at V_{IN} (UVLO), UV/OV, or the fault latch. GATE is actively servoed to control fault current as measured at SENSE. A compensation capacitor at GATE stabilizes this loop. A comparator monitors GATE to ensure that it is low before allowing an initial timing cycle, GATE ramp up after an overvoltage event, or restart after a current limit fault.

OPERATION

Higher overloads are handled by an analog current limit loop. If the drop across R_S reaches 100mV, the current limiting loop servos the MOSFET gate and maintains a constant output current of $100\text{mV}/R_S$. Note that because $\text{SENSE} > 50\text{mV}$, TIMER charges C_T during this time and the LTC4251/LTC4251-1/LTC4251-2 will eventually shut down.

Low impedance failures on the load side of the LTC4251/LTC4251-1/LTC4251-2 coupled with 48V or more driving potential can produce current slew rates well in excess of $50\text{A}/\mu\text{s}$. Under these conditions, overshoot is inevitable. A fast SENSE comparator with a threshold of 200mV detects overshoot and pulls GATE low much harder and hence much faster than can the weaker current limit loop. The $100\text{mV}/R_S$ current limit loop then takes over, and servos the current as previously described. As before, TIMER runs and latches the LTC4251/LTC4251-1/LTC4251-2 off when C_T reaches 4V.

The LTC4251/LTC4251-1/LTC4251-2 circuit breaker latch is reset by either pulling UV/OV momentarily low, or dropping the input voltage V_{IN} below the internal UVLO threshold of 8.2V.

Although short-circuits are the most obvious fault type, several operating conditions may invoke overcurrent protection. Noise spikes from the backplane or load, input steps caused by the connection of a second, higher voltage supply, transient currents caused by faults on adjacent circuit boards sharing the same power bus, or the insertion of non-hot swappable products could cause higher than anticipated input current and temporary detection of an overcurrent condition. The action of TIMER and C_T rejects these events allowing the LTC4251/LTC4251-1/LTC4251-2 to “ride out” temporary overloads and disturbances that would trip a simple current comparator and in some cases, blow a fuse.

APPLICATIONS INFORMATION (Refer to Block Diagram)

SHUNT REGULATOR

A fast responding regulator shunts the LTC4251/LTC4251-1/LTC4251-2 V_{IN} pin. Power is derived from -48RTN by an external current limiting resistor. The shunt regulator clamps V_{IN} to 13V (V_Z). A $1\mu\text{F}$ decoupling capacitor at V_{IN} filters supply transients and contributes a short delay at start-up. A $10\text{k } 1/2\text{W}$ (R_{IN}) resistor can be two $5\text{k } 1/4\text{W}$ resistors in series.

INTERNAL UNDERVOLTAGE LOCKOUT (UVLO)

Internal circuitry monitors V_{IN} for undervoltage. The exact thresholds are defined by V_{LKO} and its hysteresis, V_{LKH} . When V_{IN} rises above 9.2V (V_{LKO}) the chip is enabled; below 8.2V ($V_{\text{LKO}} - V_{\text{LKH}}$) it is disabled and GATE is pulled low. The UVLO function at V_{IN} should not be confused with the UV/OV pin. These are completely separate functions.

UV/OV COMPARATORS

Two hysteretic comparators for detecting under- and overvoltage conditions, with the following thresholds, monitor the dual function UV/OV pin:

UV turning on at V_{UVHI}

UV turning off at V_{UVLO}

OV turning off at V_{OVHI}

OV turning on at V_{OVLO}

The UV and OV trip point ratio for LTC4251 is designed to match the standard telecom operating range of 43V to 75V. The LTC4251-2 implements a UV threshold of 43V only.

A divider (R_1 , R_2) is used to scale the supply voltage. Using $R_1 = 402\text{k}$ and $R_2 = 32.4\text{k}$ gives a typical operating range of 43.2V to 74.4V. The under- and overvoltage shutdown thresholds are then 39.2V and 82.5V. 1% divider resistors are recommended to preserve threshold accuracy. The same resistor values can be used for the LTC4251-2.

APPLICATIONS INFORMATION

The R1-R2 divider values shown in the Typical Application set a standing current of slightly more than 100 μ A, and define an impedance at UV/OV of 30k. In most applications, 30k impedance coupled with 300mV UV hysteresis makes the LTC4251/LTC4251-1/LTC4251-2 insensitive to noise. If more noise immunity is desired, add a 1nF to 10nF filter capacitor from UV/OV to V_{EE}.

The UV and OV trip point thresholds for the LTC4251-1 are designed to encompass the standard telecom operating range of –36V to –72V.

A divider (R1, R2) is used to scale the supply voltage. Using R1 = 442k and R2 = 34.8k gives a typical operating range of 33.2V to 81V. The typical under- and overvoltage shutdown thresholds are then 29.6V and 84.5V. 1% divider resistors are recommended to preserve threshold accuracy.

The R1-R2 divider values shown in the Typical Application set a standing current of slightly more than 100 μ A, and define an impedance at UV/OV of 32k. In most applications, 32k impedance coupled with 260mV UV hysteresis makes the LTC4251-1 insensitive to noise. If more noise immunity is desired, add a 1nF to 10nF filter capacitor from UV/OV to V_{EE}.

UV/OV OPERATION

A low input to the UV comparator will reset the chip and pull the GATE and TIMER pins low. A low-to-high UV transition will initiate an initial timing sequence if the three remaining interlock conditions are met.

Overvoltage conditions detected by the OV comparator will also pull GATE low, thereby shutting down the load, but it will not reset the circuit breaker latch. Returning the supply voltage to an acceptable range restarts the GATE pin provided all interlock conditions except TIMER are met.

TIMER

The operation of the TIMER pin is somewhat complex as it handles several key functions. A capacitor, C_T, is used at TIMER to provide timing for the LTC4251/LTC4251-1/LTC4251-2. Four different charging and discharging modes are available at TIMER:

1. 5.8 μ A slow charge; initial timing delay
2. 230 μ A fast charge; circuit breaker delay
3. 5.8 μ A slow discharge; circuit breaker “cool-off”
4. Low impedance switch; resets capacitor after initial timing delay, in undervoltage lockout, and in overvoltage

For initial startup, the 5.8 μ A pull-up is used. The low impedance switch is turned off and the 5.8 μ A current source is enabled when the four interlock conditions are met. C_T charges to 4V in a time period given by:

$$t = \frac{4V \cdot C_T}{5.8\mu A} \quad (1)$$

When C_T reaches 4V (V_{TMRH}), the low impedance switch turns on and discharges C_T. The GATE output is enabled and the load turns on.

CIRCUIT BREAKER TIMER OPERATION

If the SENSE pin detects more than 50mV across R_S, the TIMER pin charges C_T with 230 μ A. If C_T charges to 4V, the GATE pin pulls low and the LTC4251/LTC4251-1/LTC4251-2 latch off. The part remains latched off until either the UV/OV pin is momentarily pulsed low, or V_{IN} dips into UVLO and is then restored. The circuit breaker timeout period is given by

$$t = \frac{4V \cdot C_T}{230\mu A} \quad (2)$$

Intermittent overloads may exceed the 50mV threshold at SENSE, but if their duration is sufficiently short TIMER will not reach 4V and the LTC4251/LTC4251-1/LTC4251-2 will not latch off. To handle this situation, the TIMER discharges C_T slowly with a 5.8 μ A pull-down whenever the SENSE voltage is less than 50mV. Therefore any intermittent overload with an aggregate duty cycle of 2.5% or more will eventually trip the circuit breaker and latch off the LTC4251/LTC4251-1/LTC4251-2. Figure 3 shows the circuit breaker response time in seconds normalized to 1 μ F. The asymmetric charging and discharging of C_T is a fair gauge of MOSFET heating.

APPLICATIONS INFORMATION

Figure 3. Circuit Breaker Response Time

GATE

GATE is pulled low to V_{EE} under any of the following conditions: in UVLO, during the initial timing cycle, in an overvoltage condition, or when the LTC4251/LTC4251-1/LTC4251-2 are latched off after a short-circuit. When GATE turns on, a 58μA current source charges the MOSFET gate and any associated external capacitance. V_{IN} limits gate drive to no more than 14.5V.

Gate-drain capacitance (C_{GD}) feed through at the first abrupt application of power can cause a gate-source voltage sufficient to turn on the MOSFET. A unique circuit pulls GATE low with practically no usable voltage at V_{IN} , and eliminates current spikes at insertion. A large external gate-source capacitor is thus unnecessary for the purpose of compensating C_{GD} . Instead, a smaller value ($\geq 10nF$) capacitor C_C is adequate. C_C also provides compensation for the analog current limit loop.

SENSE

The SENSE pin is monitored by the circuit breaker (CB) comparator, the analog current limit (ACL) amplifier, and the fast current limit (FCL) comparator. Each of these three measures the potential of SENSE relative to V_{EE} . If SENSE exceeds 50mV, the CB comparator activates the 230μA TIMER pull-up. At 100mV, the ACL amplifier servos the MOSFET current, and at 200mV the FCL comparator abruptly pulls GATE low in an attempt to bring the MOSFET current under control. If any of these conditions persists long enough for TIMER to charge C_T to 4V (see Equation (2)), the LTC4251/LTC4251-1/LTC4251-2 latch off and pull GATE low.

If the SENSE pin encounters a voltage greater than 100mV, the ACL amplifier will servo GATE downwards in an attempt to control the MOSFET current. Since GATE overdrives the MOSFET in normal operation, the ACL amplifier needs time to discharge GATE to the threshold of the MOSFET. For a mild overload, the ACL amplifier can control the MOSFET current, but in the event of a severe overload the current may overshoot. At SENSE = 200mV, the FCL comparator takes over, quickly discharging the GATE pin to near V_{EE} potential. FCL then releases, and the ACL amplifier takes over. All the while TIMER is running. The effect of FCL is to add a nonlinear response to the control loop in favor of reducing MOSFET current.

Owing to inductive effects in the system, FCL typically overcorrects the current limit loop, and GATE undershoots. A zero in the loop (resistor R_C in series with the gate capacitor) helps the ACL amplifier recover.

SHORT-CIRCUIT OPERATION

Circuit behavior arising from a load-side low impedance short is shown in Figure 4. Initially, the current overshoots the analog current limit level of $V_{SENSE} = 100mV$ (Trace 2) as the GATE pin works to bring V_{GS} under control (Trace 3). The overshoot glitches the backplane in the negative direction, and when the current is reduced to $100mV/R_S$ the backplane responds by glitching in the positive direction.

TIMER commences charging C_T (Trace 4) while the analog current limit loop maintains the fault current at $100mV/R_S$, which in this case is 5A (Trace 2). Note that the backplane voltage (Trace 1) sags under load. When C_T reaches 4V, GATE turns off, the load current drops to zero and the backplane rings up to over 100V. The positive peak is usually limited by avalanche breakdown in the MOSFET, and can be further limited by adding a zener diode across the input from $-48V$ to $-48RTN$, such as Diodes Inc. SMAT70A.

A low-impedance short on one card may influence the behavior of others sharing the same backplane. The initial glitch and backplane sag as seen in Figure 4, Trace 1, can rob charge from output capacitors on adjacent cards. When the faulty card shuts down, current flows in to refresh the

APPLICATIONS INFORMATION

capacitors. If LTC4251, LTC4251-1 or LTC4251-2s are used throughout, they respond by limiting the inrush current to a value of $100\text{mV}/R_S$. If C_T is sized correctly, the capacitors will recharge long before C_T times out.

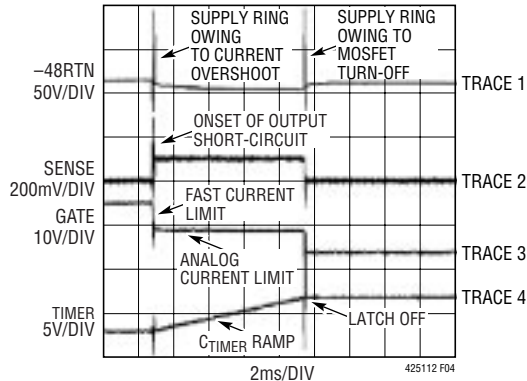

Figure 4. Output Short-Circuit Behavior
(All Waveforms are Referenced to V_{EE})

MOSFET SELECTION

The external MOSFET switch must have adequate safe operating area (SOA) to charge the load capacitance on start-up and handle short-circuit conditions until TIMER latchoff. These considerations take precedence over DC current ratings. A MOSFET with adequate SOA for a given application can always handle the required current, but the opposite cannot be said. Consult the manufacturer's MOSFET data sheet for safe operating area and effective transient thermal impedance curves.

MOSFET selection is a three-step process. First, R_S is calculated, and then the time required to charge the load capacitance is determined. This timing, along with the maximum short-circuit current and maximum input voltage defines an operating point that is checked against the MOSFET's SOA curve.

To begin a design, first specify the required load current and load capacitance, I_L and C_L . The circuit breaker current trip point ($50\text{mV}/R_S$) should be set to accommodate the maximum load current. Note that maximum input current to a DC/DC converter is expected at $V_{SUPPLY(MIN)}$. R_S is given by:

$$R_S = \frac{40\text{mV}}{I_L(\text{MAX})} \quad (3)$$

where 40mV represents the guaranteed minimum circuit breaker threshold.

During the initial charging process, the LTC4251/LTC4251-1/LTC4251-2 may operate the MOSFET in current limit, forcing 80mV to 120mV across R_S . The minimum inrush current is given by:

$$I_{\text{INRUSH(MIN)}} = \frac{80\text{mV}}{R_S} \quad (4)$$

Maximum short-circuit current limit is calculated using maximum V_{SENSE} , or:

$$I_{\text{SHORT-CIRCUIT(MAX)}} = \frac{120\text{mV}}{R_S} \quad (5)$$

The TIMER capacitor C_T must be selected based on the slowest expected charging rate; otherwise TIMER might time out before the load capacitor is fully charged. A value for C_T is calculated based on the maximum time it takes the load capacitor to charge. That time is given by:

$$t_{\text{CL CHARGE}} = \frac{C \cdot V}{I} = \frac{C_L \cdot V_{\text{SUPPLY(MAX)}}}{I_{\text{INRUSH(MIN)}}} \quad (6)$$

Substituting Equation (4) for $I_{\text{INRUSH(MIN)}}$ and equating (6) with (2) gives:

$$C_T = \frac{C_L \cdot V_{\text{SUPPLY(MAX)}} \cdot R_S \cdot 230\mu\text{A}}{(4\text{V} \cdot 80\text{mV})} \quad (7)$$

Returning to Equation (2), the TIMER period is calculated and used in conjunction with $V_{\text{SUPPLY(MAX)}}$ and $I_{\text{SHORT-CIRCUIT(MAX)}}$ to check the SOA curves of a prospective MOSFET.

As a numerical design example, consider a 30W load, which requires 1A input current at 36V. If $V_{\text{SUPPLY(MAX)}} = 72\text{V}$ and $C_L = 100\mu\text{F}$, Equation (3) gives $R_{\text{SENSE}} = 40\text{m}\Omega$; Equation (7) gives $C_T = 207\text{nF}$. To account for errors in R_{SENSE} , C_T , TIMER current (230 μA) and TIMER threshold (4V), the calculated value should be multiplied by 1.5, giving a nearest standard value of $C_T = 330\text{nF}$.

If a short-circuit occurs, a current of up to $120\text{mV}/40\text{m}\Omega = 3\text{A}$ will flow in the MOSFET for 5.7ms as dictated by

APPLICATIONS INFORMATION

$C_T = 330\text{nF}$ in Equation (2). The MOSFET must be selected based on this criterion. The IRF530S can handle 100V and 3A for 10ms, and is safe to use in this application.

SUMMARY OF DESIGN FLOW

To summarize the design flow, consider the application shown in Figure 2, which was designed for 50W:

Calculate maximum load current: $50\text{W}/36\text{V} = 1.4\text{A}$; allowing 83% converter efficiency, $I_{IN(\text{MAX})} = 1.7\text{A}$.

Calculate R_S : from Equation (3) $R_S = 20\text{m}\Omega$.

Calculate C_T : from Equation (7) $C_T = 150\text{nF}$ (including 1.5X correction factor).

Calculate TIMER period: from Equation (2) the short-circuit time-out period is $t = 2.6\text{ms}$.

Calculate maximum short-circuit current: from Equation (5) maximum short-circuit current could be as high as $120\text{mV}/20\text{m}\Omega = 6\text{A}$.

Consult MOSFET SOA curves: the IRF530S can handle 6A at 72V for 5ms, so it is safe to use in this application.

FREQUENCY COMPENSATION

The LTC4251/LTC4251-1/LTC4251-2 typical frequency compensation network for the analog current limit loop is a series R_C (10Ω) and C_C connected to V_{EE} . Figure 5 depicts the relationship between the compensation capacitor C_C and the MOSFET's C_{ISS} . The line in Figure 5 is used to select a starting value for C_C based upon the MOSFET's C_{ISS} specification. Optimized values for C_C are shown for several popular MOSFETs. Differences in the optimized value of C_C versus the starting value are small. Nevertheless, compensation values should be verified by board level short-circuit testing.

As seen in Figure 4 previously, at the onset of a short-circuit event, the input supply voltage can ring dramatically owing to series inductance. If this voltage avalanches the MOSFET, current continues to flow through the MOSFET to the output. The analog current limit loop cannot control this current flow and therefore the loop undershoots. This effect cannot be eliminated by frequency compensation. A

zener diode is required to clamp the input supply voltage and prevent MOSFET avalanche.

Figure 5. Recommended Compensation Capacitor C_C vs MOSFET C_{ISS}

SENSE RESISTOR CONSIDERATIONS

For proper circuit breaker operation, Kelvin-sense PCB connections between the sense resistor and the V_{EE} and SENSE pins are strongly recommended. The drawing in Figure 6 illustrates the correct way of making connections between the LTC4251/LTC4251-1/LTC4251-2 and the sense resistor. PCB layout should be balanced and symmetrical to minimize wiring errors. In addition, the PCB layout for the sense resistor should include good thermal management techniques for optimal sense resistor power dissipation.

TIMING WAVEFORMS

System Power-Up

Figure 7 details the timing waveforms for a typical power-up sequence in the case where a board is already installed in the backplane and system power is applied abruptly. At time point 1, the supply ramps up, together with UV/OV

APPLICATIONS INFORMATION

and V_{OUT} . V_{IN} follows at a slower rate as set by the V_{IN} bypass capacitor. At time point 2, V_{IN} exceeds V_{LKO} and the internal logic checks for $V_{UVHI} < UV/OV < V_{OVLO}$, $TIMER < V_{TMRL}$, $GATE < V_{GATEL}$ and $SENSE < V_{CB}$. When all conditions are met, an initial timing cycle starts and the $TIMER$ capacitor is charged by a $5.8\mu A$ current source pull-up. At time point 3, $TIMER$ reaches the V_{TMRH} threshold and the initial timing cycle terminates. The $TIMER$ capacitor is then quickly discharged. At time point 4, the V_{TMRL} threshold is reached and the conditions of $GATE < V_{GATEL}$ and $SENSE < V_{CB}$ must be satisfied before a start-up cycle is allowed to begin. $GATE$ sources $58\mu A$ into the external MOSFET gate and compensation network. When the $GATE$ voltage reaches the MOSFET's threshold, current begins flowing into the load capacitor. At time point 5, the $SENSE$ voltage ($V_{SENSE} - V_{EE}$) reaches the V_{CB} threshold and activates the $TIMER$. The $TIMER$ capacitor is charged by a $230\mu A$ current-source pull-up. At time point 6, the analog current limit loop activates. Between time point 6 and time point 7, the $GATE$ voltage is held essentially constant and the sense voltage is regulated at V_{ACL} . As the load capacitor nears full charge, its current begins to decline. At point 7, the load current falls and the sense voltage drops below V_{ACL} . The analog current limit loop shuts off and the $GATE$ pin ramps further. At time point 8, the sense voltage drops below V_{CB} and $TIMER$ now discharges through a $5.8\mu A$ current source pull-down. At time point 9, $GATE$ reaches its maximum voltage as determined by V_{IN} .

Live Insertion with Short Pin Control of UV/OV

In this example as shown in Figure 8, power is delivered through long connector pins whereas the UV/OV divider makes contact through a short pin. This ensures the power connections are firmly established before the LTC4251/LTC4251-1/LTC4251-2 are activated. At time point 1, the power pins make contact and V_{IN} ramps through V_{LKO} . At time point 2, the UV/OV divider makes contact and its voltage exceeds V_{UVHI} . In addition, the internal logic checks for $V_{UVHI} < UV/OV < V_{OVHI}$, $TIMER < V_{TMRL}$, $GATE < V_{GATEL}$ and $SENSE < V_{CB}$. When all conditions are met, an initial timing cycle starts and the $TIMER$ capacitor is charged by a $5.8\mu A$ current source pull-up. At time point 3, $TIMER$ reaches the V_{TMRH} threshold and the initial

timing cycle terminates. The $TIMER$ capacitor is then quickly discharged. At time point 4, the V_{TMRL} threshold is reached and the conditions of $GATE < V_{GATEL}$ and $SENSE < V_{CB}$ must be satisfied before a start-up cycle is allowed to begin. $GATE$ sources $58\mu A$ into the external MOSFET gate and compensation network. When the $GATE$ voltage reaches the MOSFET's threshold, current begins flowing into the load capacitor. At time point 5, the $SENSE$ voltage ($V_{SENSE} - V_{EE}$) reaches the V_{CB} threshold and activates the $TIMER$. The $TIMER$ capacitor is charged by a $230\mu A$ current source pull-up. At time point 6, the analog current limit loop activates. Between time point 6 and time point 7, the $GATE$ voltage is held essentially constant and the sense voltage is regulated at V_{ACL} . As the load capacitor nears full charge, its current begins to decline. At time point 7, the load current falls and the sense voltage drops below V_{ACL} . The analog current limit loop shuts off and the $GATE$ pin ramps further. At time point 8, the sense voltage drops below V_{CB} and $TIMER$ now discharges through a $5.8\mu A$ current source pull-down. At time point 9, $GATE$ reaches its maximum voltage as determined by V_{IN} .

Undervoltage Lockout Timing

In Figure 9, when UV/OV drops below V_{UVLO} (time point 1), $TIMER$ and $GATE$ pull low. If current has been flowing, the $SENSE$ pin voltage decreases to zero as $GATE$ collapses. When UV/OV recovers and clears V_{UVHI} (time point 2), an initial time cycle begins followed by a start-up cycle.

Undervoltage Timing with Overvoltage Glitch

In Figure 10, when UV/OV clears V_{UVHI} (time point 1), an initial timing cycle starts. If the system bus voltage overshoots V_{OVHI} as shown at time point 2, $TIMER$ discharges. At time point 3, the supply voltage recovers and drops below the V_{OVLO} threshold. The initial timing cycle restarts followed by a start-up cycle.

Overvoltage Timing

During normal operation, if UV/OV exceeds V_{OVHI} as shown at time point 1 of Figure 11, the $TIMER$ status is unaffected. Nevertheless, $GATE$ pulls down and disconnects the load. At time point 2, UV/OV recovers and drops below the V_{OVLO} threshold. A gate ramp up cycle ensues.

APPLICATIONS INFORMATION

If the overvoltage glitch is long enough to deplete the load capacitor, a full start-up cycle may occur as shown between time points 3 through 6.

Timer Behavior

In Figure 12a, the TIMER capacitor charges at $230\mu\text{A}$ if the SENSE pin exceeds V_{CB} . It is discharged with $5.8\mu\text{A}$ if the

Figure 7. System Power-Up Timing (All Waveforms are Referenced to V_{EE})

Figure 8. Power-Up Timing with a Short-Pin (All Waveforms are Referenced to V_{EE})

APPLICATIONS INFORMATION

SENSE pin is less than V_{CB} . In Figure 12b, when TIMER exceeds V_{TMRH} , TIMER is latched high by the $5.8\mu A$ pull-up and GATE pulls down immediately. In Figure 12c, multiple momentary faults cause the TIMER capacitor to integrate until it latches.

Analog Current Limit and Fast Current Limit

In Figure 13a, when SENSE exceeds V_{ACL} , GATE is regulated by the analog current limit amplifier loop. When SENSE drops below V_{ACL} , GATE is allowed to pull up. In Figure 13b, when a severe fault occurs, SENSE exceeds V_{FCL} and GATE immediately pulls down until the analog

current amplifier can establish control. If TIMER reaches V_{TMRH} , GATE pulls low and latches off.

Resetting a Fault Latch

As shown in Figure 14, a latched fault is reset by either pulling UV/OV below V_{UVLO} or pulling TIMER below V_{TMRL} . An initial timing cycle is initiated if UV/OV is used for reset. If TIMER is used for reset, the initial timing cycle is skipped.

Internal Soft-Start

An internal soft-start feature ramps the positive input of the analog current limit amplifier during initial start-up.

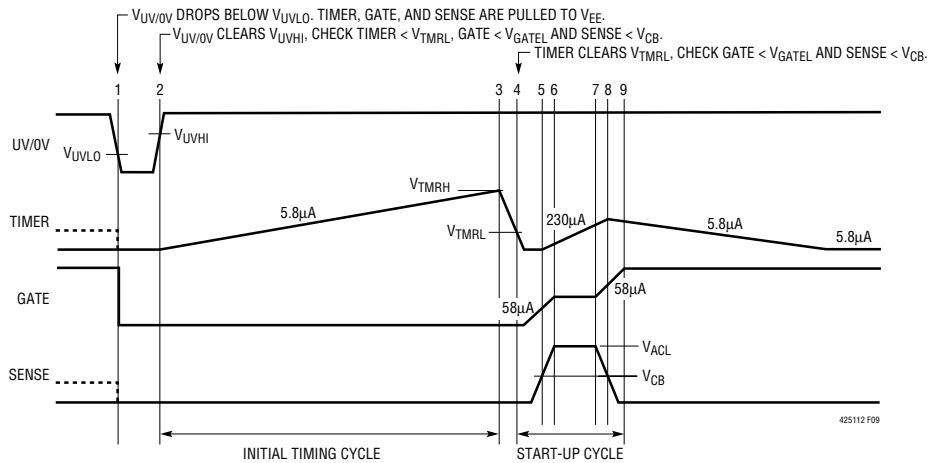

Figure 9. Undervoltage Lockout Timing (All Waveforms are Referenced to V_{EE})

Figure 10. Undervoltage Timing with an Overvoltage Glitch (All Waveforms are Referenced to V_{EE})

APPLICATIONS INFORMATION

The ramp duration is approximately 200 μ s. This feature reduces load current di/dt at start-up. As illustrated in Figure 15, soft-start is initiated by a TIMER transition from

V_{TMRH} to V_{TMRL} or when UV/OV falls below the V_{OVL0} threshold after an OV fault. After soft-start duration, load current is limited by V_{ACL}/R_S .
