

# MAXIM

## Microprocessor Supervisory Circuits

MAX696/697

### General Description

The MAX696/697 supervisory circuits reduce the complexity and number of components required for power supply monitoring and battery control functions in microprocessor systems. These include  $\mu P$  reset and backup-battery switchover, watchdog timer, CMOS RAM write protection, and power-failure warning. The MAX696/697 significantly improves system reliability and accuracy compared to that obtained with separate ICs or discrete components.

The MAX696 and MAX697 are supplied in 16 pin packages and perform six functions:

1. A Reset output during power-up, power-down and brownout conditions. The threshold for this "low line" reset is adjustable by an external voltage divider.
2. A Reset pulse if the optional watchdog timer has not been toggled within a specified time.
3. Individual outputs for low line and watchdog fault conditions.
4. The Reset time may be left at its default value of 50 ms. or may be varied with an external capacitor or clock pulses.
5. A separate 1.3 volt threshold detector for power fail warning, low battery detection, or to monitor a power supply other than  $V_{CC}$ .

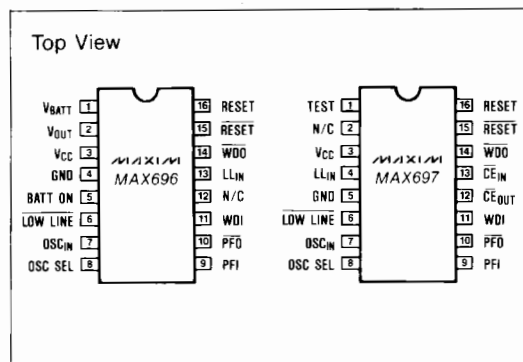

The MAX696 also has battery backup switching for CMOS RAM, CMOS microprocessor, or other low power logic.

The MAX697 lacks battery backup switching, but has write protection pins ( $CE_{IN}$  and  $CE_{OUT}$ ) for CMOS RAM or EPROM. In addition, it consumes less than 250 microamperes.

### Applications

Computers  
Controllers  
Intelligent Instruments  
Automotive Systems  
Critical  $\mu P$  Power Monitoring

### Pin Configurations

### Features

- ◆ Adjustable Low Line monitor and Power Down Reset
- ◆ Power OK/Reset Time Delay
- ◆ Watchdog Timer—100ms, 1.6 sec, or adjustable
- ◆ Minimum Component Count
- ◆ 1 $\mu A$  Standby Current
- ◆ Battery Backup Power Switching (MAX696)
- ◆ Onboard Gating of Chip Enable Signals (MAX697)
- ◆ Separate Monitor for Power Fail or Low Battery Warning

### Ordering Information

PART	TEMP RANGE	PACKAGE
MAX696C/D	0°C to +70°C	Dice
MAX696CPE	0°C to +70°C	16 Lead Plastic DIP
MAX696CWE	0°C to +70°C	16 Lead Wide SO
MAX696EPE	-40°C to +85°C	16 Lead Plastic DIP
MAX696EJE	-40°C to +85°C	16 Lead CERDIP
MAX696EWE	-40°C to +85°C	16 Lead Wide SO
MAX696MJE	-55°C to +125°C	16 Lead CERDIP
MAX697C/D	0°C to +70°C	Dice
MAX697CPE	0°C to +70°C	16 Lead Plastic DIP
MAX697CWE	0°C to +70°C	16 Lead Wide SO
MAX697EPE	-40°C to +85°C	16 Lead Plastic DIP

**Note 1:** The input voltage limits on PFI and WDI may be exceeded providing the input current is limited to less than 10mA.

**Note 2:** WDI is guaranteed to be in the mid-level (inactive) state if WDI is floating and V<sub>CC</sub> is in the operating voltage range. WDI is internally biased to 38% of V<sub>CC</sub> with an impedance of approximately 125 kilohms.

**Note 3:** T<sub>A</sub> = Full Operating Range.

## Microprocessor Supervisory Circuits

### Pin Description

NAME	PIN		FUNCTION
	MAX696	MAX697	
V <sub>CC</sub>	3	3	The +5V input.
V <sub>BATT</sub>	1	—	Backup battery input. Connect to Ground if a backup battery is not used.
V <sub>OUT</sub>	2	—	The higher of V <sub>CC</sub> or V <sub>BATT</sub> is internally switched to V <sub>OUT</sub> . Connect V <sub>OUT</sub> to V <sub>CC</sub> if V <sub>OUT</sub> and V <sub>BATT</sub> are not used.
GND	4	5	0V ground reference for all signals.
RESET	15	15	RESET goes low whenever LL <sub>IN</sub> falls below 1.3 volts or V <sub>CC</sub> falls below the V <sub>BATT</sub> input voltage. RESET remains low for 50ms after LL <sub>IN</sub> goes above 1.3 volts. RESET also goes low for 50ms if the Watchdog Timer is enabled but not serviced within its timeout period. The RESET pulse width can be adjusted as shown in Table 1.
WDI	11	11	The watchdog input, WDI, is a three level input. If WDI remains either high or low for longer than the watchdog timeout period, RESET pulses low and WDO goes low. The Watchdog Timer is disabled when WDI is left floating or is driven to mid-supply. The timer resets with each transition at the Watchdog Timer Input.
PFI	9	9	PFI is the non-inverting input to the Power Fail Comparator. When PFI is less than 1.3V, PFO goes low. Connect PFI to GND or V <sub>OUT</sub> when not used. See Figure 1.
PFO	10	10	PFO is the output of the Power Fail Comparator. It goes low when PFI is less than 1.3V. The comparator is turned off and PFO goes low when V <sub>CC</sub> is below V <sub>BATT</sub> .
CE IN	—	13	The input to the CE gating circuit. Connect to GND or V <sub>OUT</sub> if not used.
CE OUT	—	12	CE OUT goes low only when CE IN is low and LL <sub>IN</sub> is above 1.3V. See Figure 5.
BATT ON	5	—	BATT ON goes high when V <sub>OUT</sub> is internally switched to the V <sub>BATT</sub> input. It goes low when V <sub>OUT</sub> is internally switched to V <sub>CC</sub> . The output typically sinks 7mA and can directly drive the base of an external PNP transistor to increase the output current above the 50mA rating of V <sub>OUT</sub> .
LOW LINE	6	6	LOW LINE goes low when LL <sub>IN</sub> falls below 1.3 volts. It returns high as soon as LL <sub>IN</sub> rises above 1.3 volts. See Figure 5, Reset Timing.
RESET	16	16	RESET is an active high output. It is the inverse RESET.
OSC SEL	8	8	When OSC SEL is unconnected or driven high, the internal oscillator sets the reset time delay and watchdog timeout period. When OSC SEL is low, the external oscillator input, OSC IN, is enabled. OSC SEL has a 3μA internal pullup. See Table 1.
OSC IN	7	7	OSC IN sets the Reset delay timing and Watchdog timeout period when OSC SEL floats or is driven low. The timing can also be adjusted by connecting an external capacitor to this pin. See Figure 7. When OSC SEL is high, OSC IN selects between fast and slow Watchdog timeout periods.
WDO	14	14	The Watchdog Output, WDO, goes low if WDI remains either high or low for longer than the Watchdog timeout period. WDO is set high by the next transition at WDI. If WDI is unconnected or at mid-supply, WDO remains high. WDO also goes high when LOW LINE goes low.
NC	12	2	NO CONNECT. Leave this pin open.
LL <sub>IN</sub>	13	4	LOW LINE INPUT. LL <sub>IN</sub> is the CMOS input to a comparator whose other input is a precision 1.3 volt reference. The output is LOW LINE and is also connected to the reset pulse generator. See Figure 2.
TEST	—	1	Used during Maxim manufacture only. Always ground this pin.

MAX696/697

## Typical Applications

### MAX696

A typical connection for the MAX696 is shown in Figure 1. CMOS RAM is powered from  $V_{OUT}$ .  $V_{OUT}$  is internally connected to  $V_{CC}$  when power is present, or to  $V_{BATT}$  when  $V_{CC}$  is less than the battery voltage.  $V_{OUT}$  can supply 50mA from  $V_{CC}$ , but if more current is required, an external PNP transistor can be added. When  $V_{CC}$  is higher than  $V_{BATT}$ , the BATT ON output goes low, providing 7mA of base drive for the external transistor. When  $V_{CC}$  is lower than  $V_{BATT}$ , an internal 200Q MOSFET connects the backup battery to  $V_{OUT}$ . The quiescent current in the battery backup mode is 1µA maximum when  $V_{CC}$  is between 0V and  $V_{BATT}$  -700mV.

### Reset Output

A voltage detector monitors  $V_{CC}$  and generates a RESET output to hold the microprocessor's RESET line low when  $LL_{IN}$  is below 1.3V. An internal monostable holds RESET low for 50ms after  $LL_{IN}$  rises above 1.3V. This prevents repeated toggling of RESET even if the  $V_{CC}$  power drops out and recovers with each power line cycle.

The crystal oscillator normally used to generate the clock for microprocessors takes several milliseconds to start. Since most microprocessors need several clock cycles to reset, RESET must be held low until the microprocessor clock oscillator has started. The power-up RESET pulse lasts 50ms to allow for this oscillator start-up time. An inverted, active high, RESET output is also supplied.

### Power Fail Detector

The MAX696 issues a non-maskable interrupt (NMI) to the microprocessor when a power failure occurs. The power line is monitored via two external resistors connected to the Power Fail Input (PFI). When the voltage at PFI falls below 1.3V, the Power Fail Output (PFO) drives the processor's NMI input low. An earlier power fail warning can be generated if the unregulated DC input of the regulator is available for monitoring.

### Watchdog Timer

The microprocessor drives the WATCHDOG INPUT (WDI) with an I/O line. When OSC IN and OSC SEL are unconnected, the microprocessor must toggle the WDI pin once every 1.6 seconds to verify proper software execution. If a hardware or software failure occurs such that WDI is not toggled, the MAX696 will issue a 50ms RESET pulse after 1.6 seconds. This typically restarts the microprocessor's power-up routine. A new RESET pulse is issued every 1.6 seconds until WDI is again strobed.

The WATCHDOG OUTPUT (WDO) goes low if the watchdog timer is not serviced within its timeout period. Once WDO goes low it remains low until a transition occurs at WDI while RESET is high. The watchdog timer feature can be disabled by leaving WDI unconnected. OSC IN and OSC SEL also allow other watchdog timing options, as shown in Table 1 and Figure 7.

### MAX697

The MAX697 is nearly identical to the MAX696. The MAX697 lacks the battery backup feature, so it does not have the  $V_{BATT}$ ,  $V_{OUT}$ , or BATT ON pins. This allows the MAX697 to consume less than 250 microamperes, and it allows the inclusion of RAM write protection pins. See Figure 2.

MAX696/697

## Detailed Description

### Battery-Switchover and $V_{OUT}$ (MAX696)

The battery switchover circuit compares  $V_{CC}$  to the  $V_{BATT}$  input, and connects  $V_{OUT}$  to whichever is higher. Switchover occurs when  $V_{CC}$  is 50mV greater than  $V_{BATT}$  as  $V_{CC}$  falls, and when  $V_{CC}$  is 70mV more than  $V_{BATT}$  as  $V_{CC}$  rises (See Figure 3). The switchover comparator has 20mV of hysteresis to prevent repeated, rapid switching if  $V_{CC}$  falls very slowly or remains nearly equal to the battery voltage.

When  $V_{CC}$  is higher than  $V_{BATT}$ ,  $V_{CC}$  is internally switched to  $V_{OUT}$  via a low saturation PNP transistor.  $V_{OUT}$  has 50mA output current capability. Use an external PNP pass transistor in parallel with the internal transistor if the output current requirement at  $V_{OUT}$  exceeds 50mA or if a lower  $V_{CC}$ - $V_{OUT}$  voltage differential is desired. The BATT ON output can directly drive the base of the external transistor.

It should be noted that the MAX696 need only supply the average current drawn by the CMOS RAM if there is adequate filtering. Many RAM data sheets specify a 75mA maximum supply current, but this peak current spike lasts only 100ns. A 0.1 $\mu$ F bypass capacitor at  $V_{OUT}$  supplies the high instantaneous current, while  $V_{OUT}$  need only supply the average load current, which is much less. A capacitance of 0.1 $\mu$ F or greater must be connected to the  $V_{OUT}$  terminal to ensure stability.

A 200 $\Omega$  MOSFET connects the  $V_{BATT}$  input to  $V_{OUT}$  during battery backup. This MOSFET has very low input-to-output differential (dropout voltage) at the

low current levels required for battery backup of CMOS RAM or other low power CMOS circuitry. When  $V_{CC}$  equals  $V_{BATT}$  the supply current is typically 12 $\mu$ A. When  $V_{CC}$  is between 0V and ( $V_{BATT}$  - 700mV) the typical supply current is only 600nA typical, 1 $\mu$ A maximum.

The MAX696 operates with battery voltages from 2.0V to 4.25V. The battery voltage should not be within 0.5V of  $V_{CC}$  or switchover may occur. High value capacitors, either standard electrolytic or the farad-size double layer capacitors, can also be used for short-term memory backup. The capacitor charging voltage should include a diode to limit the fully charged voltage to approximately 0.5V less than  $V_{CC}$ . The charging resistor for rechargeable batteries should be connected to  $V_{OUT}$  since this eliminates the discharge path that exists if the resistor is connected to  $V_{CC}$ .

A small leakage current of typically 10nA (20nA max) flows out of the  $V_{BATT}$  terminal. This current varies with the amount of current that is drawn from  $V_{OUT}$  but its polarity is such that the backup battery is always slightly charged, and is never discharged while  $V_{CC}$  is in its operating voltage range. This extends the shelf-life of the backup battery by compensating for its self-discharge current. Also note that this current poses no problem when lithium batteries are used for backup since the maximum current (20nA) is safe for even the smallest lithium cells.

If the battery-switchover section is not used, connect  $V_{BATT}$  to GND and connect  $V_{OUT}$  to  $V_{CC}$ . Table 2 shows the state of the inputs and output in the low power battery backup mode.

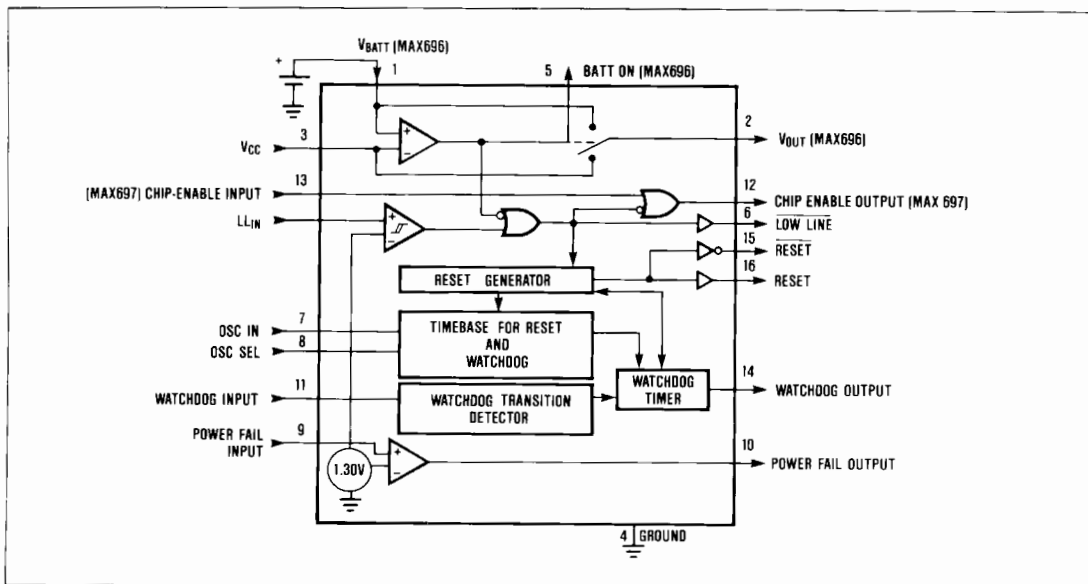

Figure 2. MAX696/697 Block Diagram

## Microprocessor Supervisory Circuits

### Reset Output

RESET is an active low output which goes low whenever  $LL_{IN}$  falls below 1.3 volts. It will remain low until  $LL_{IN}$  rises above 1.312 volts for 50 milliseconds. (See Figures 4 and 5.)

The guaranteed minimum and maximum low line thresholds of the MAX696/697 are 1.2 and 1.4 volts. The  $LL_{IN}$  comparator has approximately 12mV of hysteresis.

The response time of the reset voltage comparator is about 100 microseconds.  $LL_{IN}$  should be bypassed to ensure that glitches do not activate RESET output.

RESET also goes low if the Watchdog Timer is enabled and WDI remains either high or low longer than the watchdog timeout period. RESET has an internal  $3\mu A$  pullup, and can either connect to an open collector Reset bus or directly drive a CMOS gate without an external pullup resistor.

### CE Gating and RAM Write Protection

The MAX697 uses two pins to control the Chip Enable or Write inputs of CMOS RAMs. When  $LL_{IN}$  is  $> 1.3V$ , CE OUT is a buffered replica of CE IN, with a 50ns propagation delay. If  $LL_{IN}$  input falls below 1.3V (1.2 min., 1.4 max.) an internal gate forces CE OUT high, independent of CE IN. The CE output is also forced high when  $V_{CC}$  is less than  $V_{BATT}$ . (See Figure 4.)

CE OUT typically drives the CE, CS or Write input of battery backed up CMOS RAM. This ensures the

integrity of the data in memory by preventing write operations when  $V_{CC}$  is at an invalid level. Similar protection of EEPROMs can be achieved by using the CE OUT to drive the Store or Write inputs of an EEPROM, EAROM, or NOVRAM.

If the 50ns typical propagation delay of CE OUT is too long, connect CE IN to GND and use the resulting CE OUT to control a high speed external logic gate. A second alternative is to AND the LOW LINE output with the CE or WR signal. An external logic gate and the RESET output of the MAX696/697 can also be used for CMOS RAM write protection.

### 1.25V Comparator and Power Fail Warning

The Power Fail Input (PFI) is compared to an internal 1.3V reference. The Power Fail Output (PFO) goes low when the voltage at PFI is less than 1.3V. Typically PFI is driven by an external voltage divider which senses either the unregulated DC input to the system's  $V_{CC}$  regulator or the regulated output. The voltage divider ratio can be chosen such that the voltage at PFI falls below 1.3V several milliseconds before the  $LL_{IN}$  falls below 1.3V. PFO is normally used to interrupt the microprocessor so that data can be stored in RAM before  $LL_{IN}$  falls below 1.3V and the RESET output goes low.

The Power Fail Detector can also monitor the backup battery to warn of a low battery condition. To conserve battery power, the Power Fail Detector comparator is turned off and PFO is forced low when  $V_{CC}$  is lower than the  $V_{BATT}$  input voltage.

## Microprocessor Supervisory Circuits

MAX696/697

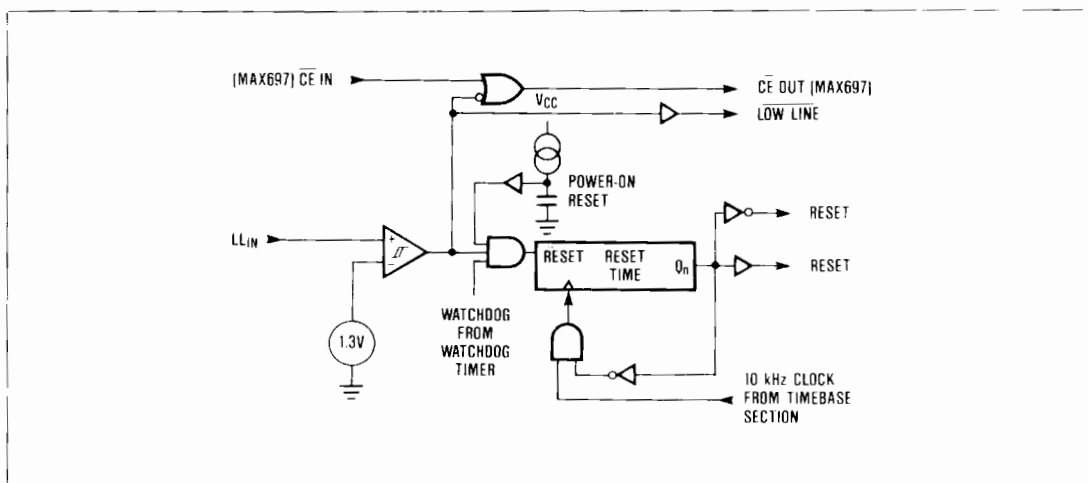

Figure 4. Reset Block Diagram

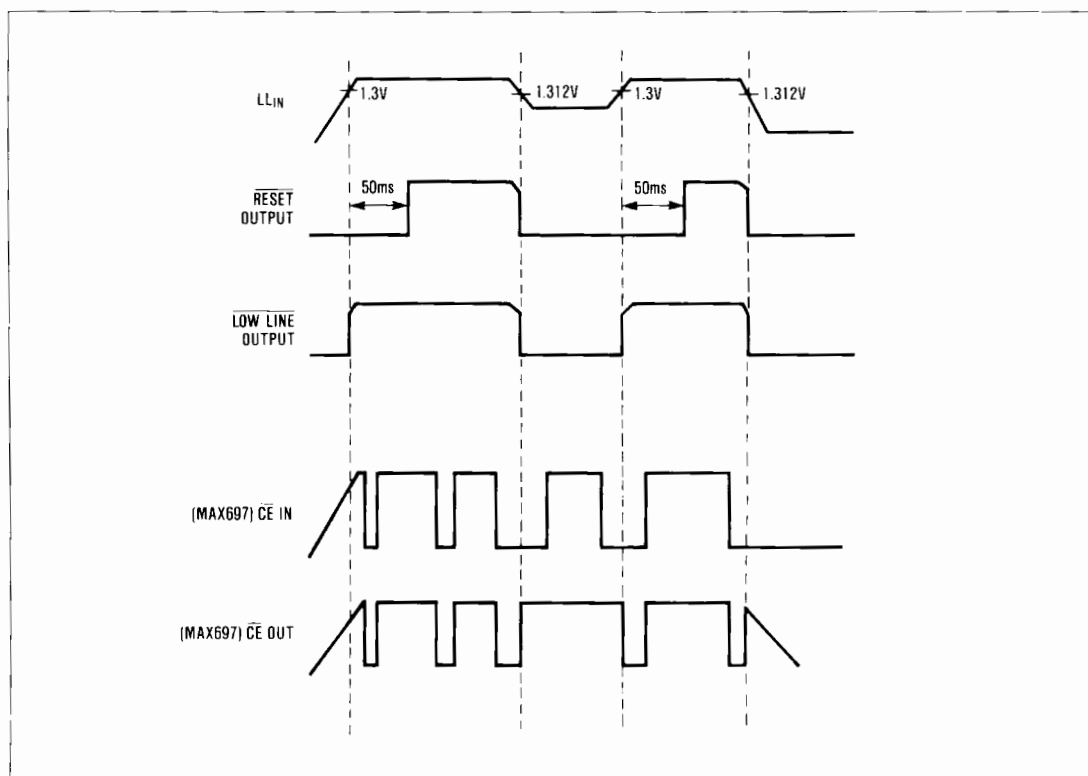

Figure 5. MAX697 Reset Timing

## Microprocessor Supervisory Circuits

### Watchdog Timer and Oscillator

The watchdog circuit monitors the activity of the microprocessor. If the microprocessor does not toggle the Watchdog Input (WDI) within the selected timeout period, a 50 milliseconds RESET pulse is generated. Since many systems cannot service the watchdog timer immediately after a reset, the MAX696/697 has a longer timeout period after a reset is issued. The normal timeout period becomes effective following the first transition of WDI after RESET has gone high. The watchdog timer is restarted at the end of Reset, whether the Reset was caused by lack of activity on WDI or by  $LL_{IN}$  falling below 1.3V. If WDI remains either high or low, reset pulses will be issued every 1.6 seconds. The watchdog monitor can be deactivated by floating the Watchdog Input (WDI).

The Watchdog Output WDO goes low if the watchdog timer "times out," and it remains low until set high by the next transition on the watchdog input. WDO is also set high when  $LL_{IN}$  goes below 1.3V.

The watchdog timeout period defaults to 1.6 seconds and the reset pulse width defaults to 50ms. The MAX696 and MAX697 allow these times to be adjusted per Table 1.

The internal oscillator is enabled when OSC SEL is high or floating. In this mode, OSC IN selects between the 1.6 second and 100ms watchdog timeout periods. In either case, immediately after a reset the timeout period is 1.6 seconds. This gives the microprocessor time to reinitialize the system. WD transmissions while RESET is low are ignored. If OSC IN is low, then the 100ms watchdog period becomes effective after the first transition of WDI. The software should be written

such that the I/O port driving WDI is left in its power-up reset state until the initialization routines are completed and the microprocessor is able to toggle WDI at the minimum watchdog timeout period of 70ms.

### Application Hints

#### Adding Hysteresis to the Power Fail Comparator

Since the power fail comparator circuit is non-inverting, hysteresis can be added by connecting a resistor between the PFO output and the PFI input as shown in Figure 7. When PFO is low, resistor R3 sinks current from the summing junction at the PFI pin. When PFO is high, the series combination of R3 and R4 source current into the PFI summing junction.

#### Alternate Watchdog Input Drive Circuits

The Watchdog feature can be enabled and disabled under program control by driving WDI with a 3-state buffer (Figure 8). The drawback to this circuit is that a software fault may erroneously 3-state the buffer, thereby preventing the MAX690 from detecting that the microprocessor is no longer working. In most cases a better method is to extend the watchdog period rather than disabling the watchdog. See Figure 9. When the control input is high, the OSC SEL pin is low and the watchdog timeout is set by the external capacitor. A 0.01 $\mu$ F capacitor sets a watchdog timeout delay of 100 seconds. When the control input is low, the OSC SEL pin is driven high, selecting the internal oscillator. The 100ms or the 1.6 sec period is chosen, depending on which diode in Figure 9 is used.

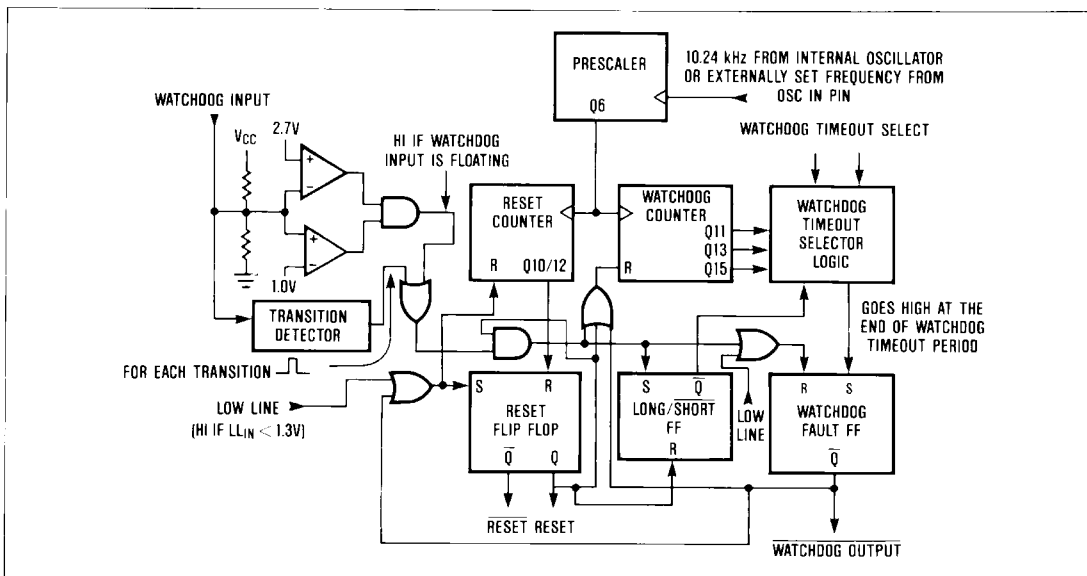

Figure 6. Watchdog Timer Block Diagram

# Microprocessor Supervisory Circuits

MAX696/697

Table 1. MAX696 and MAX697 Reset Pulse Width and Watchdog Timeout Selections

OSC SEL (Note 3)	OSC IN	WATCHDOG TIMEOUT PERIOD		RESET TIMEOUT PERIOD
		NORMAL	IMMEDIATELY AFTER RESET	
Low	External Clock Input	1024 clks	4096 clks	512 clks
Low	External Capacitor	$400\text{ms} \times C$ $47\text{pf}$	$1.6 \text{ sec} \times C$ $47\text{pf}$	$200\text{ms} \times C$ $47\text{pf}$
High/Floating	Low	100ms	1.6 sec	50ms
High/Floating	Floating	1.6 sec	1.6 sec	50ms

**Note 1:** When the MAX696/697 OSC SEL pin is low, OSC IN can be driven by an external clock signal, or an external capacitor can be connected between OSC IN and GND. The nominal internal oscillator frequency is 10.24kHz. The nominal oscillator frequency with external capacitor is  $F_{\text{osc}}(\text{Hz}) = \frac{184,000}{C_{\text{osc}}(\text{pF})}$

**Note 2:** See Electrical Characteristics Table for minimum and maximum timing values.

**Note 3:** "HIGH" for the OSC SEL pin should be connected to  $V_{\text{OUT}}$ , not  $V_{\text{CC}}$  (on MAX696).

## Microprocessor Supervisory Circuits

Table 2. Input and Output Status in Battery Backup Mode

$V_{BATT}$ , $V_{OUT}$	$V_{BATT}$ is connected to $V_{OUT}$ via internal MOSFET. (MAX696 only)
$\overline{RESET}$	Logic low
$RESET$	Logic high. The open circuit output voltage is equal to $V_{OUT}$ .
$\overline{LOW\ LINE}$	Logic low
$BATT\ ON$	Logic high (MAX696 only)
$WDI$	$WDI$ is internally disconnected from its internal pullup and does not source or sink current as long as its input voltage is between GND and $V_{OUT}$ . The input voltage does not affect supply current.
$\overline{WDO}$	Logic high
$PFI$	The Power Fail Comparator is turned off and the Power Fail Input voltage has no effect on the Power Fail Output.
$\overline{PFO}$	Logic low
$\overline{CE\ IN}$	$\overline{CE\ IN}$ is internally disconnected from its internal pullup and does not source or sink current as long as its input voltage is between GND and $V_{OUT}$ . The input voltage does not affect supply current. (MAX697 only)
$\overline{CE\ OUT}$	Logic high (MAX697 only)
$OSC\ IN$	$OSC\ IN$ is ignored.
$OSC\ SEL$	$OSC\ SEL$ is ignored.
$V_{CC}$	Approximately $12\mu A$ is drawn from the $V_{BATT}$ input when $V_{CC}$ is between $V_{BATT} + 100mV$ and $V_{BATT} - 700mV$ . The supply current is $1\mu A$ maximum when $V_{CC}$ is less than $V_{BATT} - 700mV$ .

### Chip Topography

Maxim cannot assume responsibility for use of any circuitry other than circuitry entirely embodied in a Maxim product. No circuit patent licenses are implied. Maxim reserves the right to change the circuitry and specifications without notice at any time.
