

High-Speed, Positive Edge-Triggered, ECL-Compatible Voltage Comparators

General Description

The MAX905/MAX906 high-speed, single and dual ECL-compatible voltage comparators eliminate oscillation by separating the comparator input and output stages with a positive edge-triggered master-slave D flip-flop. Comparator propagation delay is typically 2ns, and is insensitive to input overdrive. The MAX905 and MAX906 resolve input signals as small as 3mV and 4mV respectively.

These comparators feature separate analog and digital ground connections for maximum noise rejection, and operate from either dual supplies or from a single supply. Input common-mode voltage range extends to the negative supply rail for a wide 7.9V input voltage range with $\pm 5V$ supplies.

The MAX905 is a single ECL comparator, available in 14-pin DIP and SO packages. The MAX906 is a dual version available in 16-pin DIP and SO packages.

Applications

High-Speed A/D Converters
High-Speed Line Receivers
Peak Detectors
Threshold Detectors
High-Speed Triggers

Pin Configurations

Features

- ◆ Immune to Oscillation: Clocked Architecture
- ◆ 2ns Setup Time
- ◆ 2ns Propagation Delay
- ◆ Prop Delay Independent of Overdrive
- ◆ 3mV Input Resolution (MAX905)
- ◆ Input Range Includes Negative Supply Rail
- ◆ Single- or Dual-Supply Capability
- ◆ Separate Analog and Digital Supplies
- ◆ Low Power: 180mW/Comparator

Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE
MAX905CPD	0°C to +70°C	14 Plastic DIP
MAX905CSD	0°C to +70°C	14 Narrow SO
MAX905C/D	0°C to +70°C	Dice*
MAX905EPD	-40°C to +85°C	14 Plastic DIP
MAX905ESD	-40°C to +85°C	14 Narrow SO
MAX905MJD	-55°C to +125°C	14 Cerdip
MAX906CPE	0°C to +70°C	16 Plastic DIP
MAX906CSE	0°C to +70°C	16 Narrow SO

MAX905/MAX906

High-Speed, Positive Edge-Triggered, ECL-Compatible Voltage Comparators

ABSOLUTE MAXIMUM RATINGS

Analog Supply Voltage (VCC to VEE)	+12V
Digital Supply Voltage (VEE to GND)	-6V
Differential Input Voltage	(VEE - 0.2V) to (VCC + 0.2V)
Common-Mode Input Voltage	(VEE - 0.2V) to (VCC + 0.2V)
Clock Input Voltage (CLK or CLK̄)	(VEE - 0.2V) to DGND + 0.2V
Output Current (Q or Q̄)	30mA
Output Short-Circuit Duration (Q or Q̄ to GND)	Indefinite
Continuous Power Dissipation	
MAX905 DIP (derate 10.00mW/°C above +70°C)	800mW
SO (derate 8.00mW/°C above +70°C)	640mW
CERDIP (derate 9.09mW/°C above +70°C)	727mW
MAX906 DIP (derate 10.53mW/°C above +70°C)	842mW
SO (derate 8.70mW/°C above +70°C)	696mW

Operating Temperature Ranges:

MAX90_C	0°C to +70°C
MAX90_E	-40°C to +85°C
MAX90_MJD	-55°C to +125°C
Storage Temperature Range	-65°C to +150°C
Junction Temperature	-65°C to +170°C
Lead Temperature (soldering, 10 sec)	+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at those or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note 1: Guaranteed by design. Input Referred Noise Voltage uncertainty is specified over the full bandwidth of the device.

Note 2: The input common-mode voltage or either input signal voltage should not be allowed to go more than 0.2V below V_{EE} . The upper input common-mode range limit is typically $V_{CC} - 2V$, but either input can go to $V_{CC} + 0.2V$ without damage.

Note 3: Tested for $+4.75V < V_{CC} < +5.25V$ and $-5.50V < V_{EE} < -4.75V$.

Note 4: Tested with $R_{LOAD} = 50\Omega$ terminated in $-2V$.

Note 5: I_{CC} , I_{EE} and PD tested for worst-case condition of $V_{CC} = +5.25V$ and $V_{EE} = -5.5V$.

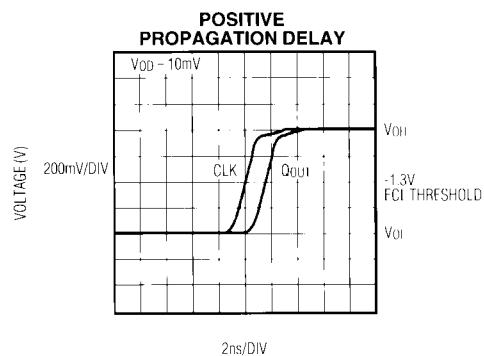

Note 6: Includes internal power dissipation due to external load resistors.

Note 7: Guaranteed by design. Measured in a high-speed fixture with $R_{LOAD} = 50\Omega$, and $C_{LOAD} = 15pF$, terminated into $-2V$.

Note 8: Clock input voltage rise and fall times should not exceed 50ns for correct triggering of comparator.

Device Overview

The MAX905 (single) and MAX906 (dual) are ultra high-speed ECL-compatible comparators with an internal positive edge-triggered master-slave D flip-flop. Unlike industry-standard ECL comparators, this architecture breaks the input-to-output signal path to accomplish the following:

- 1) Prevent oscillations caused by unwanted parasitic feedback when the comparator is in its linear region. No minimum input slew rate is required.
- 2) Propagation delay remains constant with varying input overdrive.

Detailed Description

The comparator can be divided into three stages, as shown in Figure 1:

- 1) Input Amplifier
- 2) Master-Slave D Flip-Flop
- 3) ECL Output Stage

Figure 1. MAX905/MAX906 Block Diagram

Input Amplifier

The comparator input amplifier is fully differential. Input offset voltage is trimmed to less than 1.0mV for the MAX905, and less than 1.5mV for the MAX906. Input common-mode range extends from 100mV below the negative supply rail (V_{EE}) to 2.2V below the positive supply rail (V_{CC}). Total input voltage range is 7.9V when operating from $\pm 5V$ supplies.

The master-slave architecture enables the MAX905 to compare input signals down to 3mV over its entire common-mode range. Similarly, the MAX906 compares input signals as low as 4mV (see Table 1). Any input signal less than 3mV (4mV for MAX906) may not be distinguished from the comparator's total worst-case DC error. The MAX905/MAX906 total worst-case DC error is calculated by summing input offset voltage (V_{OS}), input referred noise (e_n), common-mode rejection ratio (CMRR), and power-supply rejection ratio (PSRR). Table 1 shows the maximum total input referred error at +25°C and over temperature. For many applications, take the RMS summation of the individual errors for a more meaningful representation of the total input referred error (see Table 2).

Part	+25°C (mV)	Commercial Temp. (mV)	Ext. Ind/Military Temp. (mV)
MAX905	1.7	2.3	3.0
MAX906	2.3	3.0	3.9

Master-Slave D Flip-Flop

The master-slave D flip-flop is immune to metastability by design, and propagation delay is independent of input overdrive (V_{OD}). The MAX905/MAX906 master flip-flop has an input stage that samples the output of the input amplifier and a latch to hold the sampled data when the master input stage is disabled. The latched data is transferred to the MAX905/MAX906 slave flip-flop only on the clock's rising edge. The input amplifier continuously monitors the input signal.

Clock Cycle

Clock Low: When the clock is low, the master flip-flop's input stage samples the output of the input amplifier. The slave flip-flop maintains valid outputs from the previously sampled data. The comparator inputs are isolated from the comparator outputs because the slave flip-flop's input stage is disabled. See Figure 2.

Clock Rising Edge: On the rising edge of the clock, the master flip-flop input stage turns off and the latch holds the sampled data. Shortly after, the slave input stage turns on and samples the outputs of the master. The

ECL output stage simultaneously receives data from the slave.

Clock High: The slave flip-flop continues to sample data from the master while the clock is high. The master flip-flop latch holds data from the previous rising clock edge.

Clock Falling Edge: On the falling edge of the clock, data from the previous rising clock edge is latched into the slave, and the input of the master flip-flop is turned on. New data is not transferred to the ECL output stage on the falling edge of the clock cycle.

ECL Output Stage

The ECL output stage receives data from the slave flip-flop. Proper ECL output voltage levels and temperature coefficients are maintained by the output amplifier over commercial, extended industrial, and military temperature ranges. The comparator's outputs (Q and \bar{Q}) are fully differential and MECL 10k compatible.

Applications Information

Maximum Clock Rate

The MAX905/MAX906 maximum clock frequency is a direct function of the comparator's minimum clock setup time. Typical clock setup time is 2ns, which translates to a theoretical 500MHz maximum clock frequency. As shown in Figure 3, the maximum output toggle rate is 1/2 the clock frequency, because the comparator triggers only on the rising edge of each clock cycle.

For proper clock triggering, the MAX905/MAX906 ECL clock rise and fall times must be less than 50ns. If clock rise/fall times are greater than 50ns, the comparator may incorrectly sample the input signal at the clock's falling edge.

High-Speed, Positive Edge-Triggered, ECL-Compatible Voltage Comparators

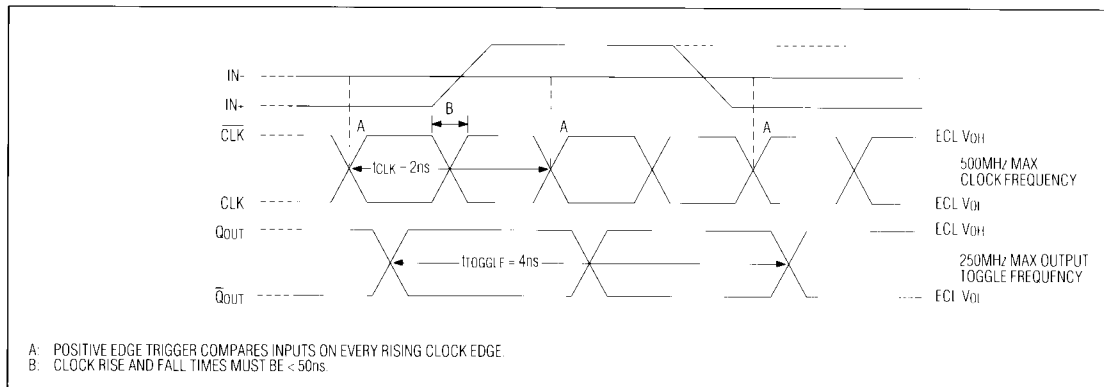

Figure 3. Maximum Clock Rate Timing Diagram

Power Supplies

The MAX905/MAX906 are tested while operating from $\pm 5V$ supplies. The comparators also operate from standard ECL +5V and -5.2V power supplies with the same guaranteed performance.

In high-speed, mixed-signal applications where a common ground is shared, a noisy digital environment can adversely affect the integrity of the analog input signal. The MAX905/MAX906 isolate the analog and digital signals by providing separate analog (AGND) and digital (DGND) grounds. For applications that cannot separate analog and digital grounds, AGND and DGND may be tied together if a good ground plane is available.

The MAX905/MAX906 offer the unique ability to operate from a single supply. The comparators' input common-mode voltage range includes the negative supply rail. Figure 4 shows the two supply voltage conditions:

- 1) Dual $\pm 5V$ Supplies (or +5V and -5.2V)
- 2) Single -5V Supply (or -5.2V)

Input Slew Rate

The MAX905/MAX906's master-slave architecture eliminates the minimum input slew-rate requirement common to standard comparator architectures. As long as the comparator is clocked after the minimum data-to-clock setup time requirement, and the input is greater

Figure 4a. $\pm 5V$ Supplies, Separate Ground*

* Separate ground is optional. DGND and AGND may be tied together.

Figure 4b. Single -5V Supply, Separate Ground*
