

**3.3 VOLT 256K X 16 FAST PAGE MODE
CMOS DYNAMIC RAM**

HIGH PERFORMANCE	40	45	50	60
Max. $\overline{\text{RAS}}$ Access Time, (t_{RAC})	40 ns	45 ns	50 ns	60 ns
Max. Column Address Access Time, (t_{CAA})	20 ns	22 ns	24 ns	30 ns
Min. Fast Page Mode Cycle Time, (t_{PC})	23 ns	25 ns	28 ns	35 ns
Min. Read/Write Cycle Time, (t_{RC})	75 ns	80 ns	90 ns	110 ns

Features

- 256K x 16-bit organization
- Fast Page Mode for a sustained data rate of 43 MHz
- $\overline{\text{RAS}}$ access time: 40, 45, 50, 60 ns
- Dual $\overline{\text{CAS}}$ Inputs
- Low power dissipation
- Read-Modify-Write, $\overline{\text{RAS}}$ -Only Refresh, $\overline{\text{CAS}}$ -Before- $\overline{\text{RAS}}$ Refresh
- Refresh Interval: 512 cycles/8 ms
- Available in 40-pin 400 mil SOJ and 40/44L-pin 400 mil TSOP-II packages
- Single +3.3V ± 0.3 V Power Supply
- TTL Interface

Description

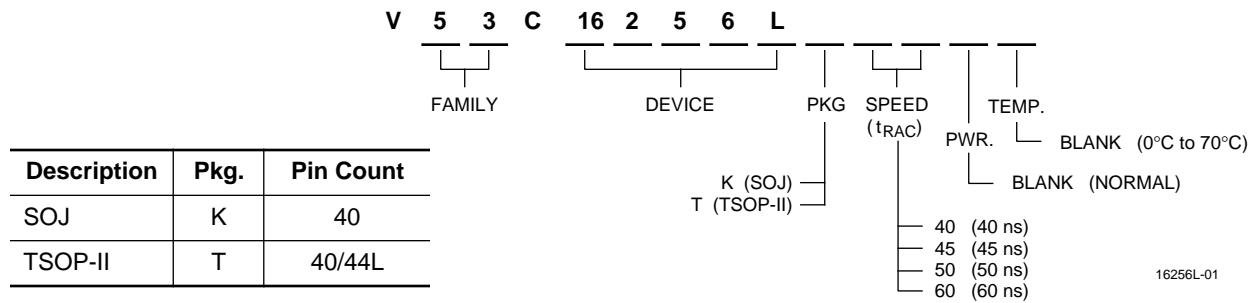

The V53C16256L is a 262,144 x 16 bit high-performance CMOS dynamic random access memory. The V53C16256L offers Fast Page mode with dual $\overline{\text{CAS}}$ inputs. An address, $\overline{\text{CAS}}$ and $\overline{\text{RAS}}$ input capacitances are reduced to one quarter when the x4 DRAM is used to construct the same memory density. The V53C16256L has symmetric address and accepts 512 cycle 8ms interval.

All inputs are TTL compatible. Fast Page Mode operation allows random access up to 512 x 16 bits, within a page, with cycle times as short as 23ns.

The V53C16256L is best suited for graphics, and DSP applications.

Notes:

1. I_{CC} is dependent on output loading when the device output is selected. Specified I_{CC} (max.) is measured with the output open.
2. I_{CC} is dependent upon the number of address transitions. Specified I_{CC} (max.) is measured with a maximum of two transitions per address cycle in Fast Page Mode.
3. Specified V_{IL} (min.) is steady state operating. During transitions, V_{IL} (min.) may undershoot to -1.0 V for a period not to exceed 20 ns. All AC parameters are measured with V_{IL} (min.) $\geq V_{SS}$ and V_{IH} (max.) $\leq V_{CC}$.
4. t_{RCD} (max.) is specified for reference only. Operation within t_{RCD} (max.) limits insures that t_{RAC} (max.) and t_{CAA} (max.) can be met. If t_{RCD} is greater than the specified t_{RCD} (max.), the access time is controlled by t_{CAA} and t_{CAC} .
5. Either t_{RRH} or t_{RCH} must be satisfied for a Read Cycle to occur.
6. Measured with a load equivalent to one TTL input and 50 pF.
7. Access time is determined by the longest of t_{CAA} , t_{CAC} and t_{CAP} .
8. Assumes that $t_{RAD} \leq t_{RAD}$ (max.). If t_{RAD} is greater than t_{RAD} (max.), t_{RAC} will increase by the amount that t_{RAD} exceeds t_{RAD} (max.).
9. Assumes that $t_{RCD} \leq t_{RCD}$ (max.). If t_{RCD} is greater than t_{RCD} (max.), t_{RAC} will increase by the amount that t_{RCD} exceeds t_{RCD} (max.).
10. Assumes that $t_{RAD} \geq t_{RAD}$ (max.).
11. Operation within the t_{RAD} (max.) limit ensures that t_{RAC} (max.) can be met. t_{RAD} (max.) is specified as a reference point only. If t_{RAD} is greater than the specified t_{RAD} (max.) limit, the access time is controlled by t_{CAA} and t_{CAC} .
12. t_{WCS} , t_{RWD} , t_{AWD} and t_{CWD} are not restrictive operating parameters.
13. t_{WCS} (min.) must be satisfied in an Early Write Cycle.
14. t_{DS} and t_{DH} are referenced to the latter occurrence of \overline{CAS} or \overline{WE} .
15. t_T is measured between V_{IH} (min.) and V_{IL} (max.). AC-measurements assume $t_T = 3$ ns.
16. Assumes a three-state test load (5 pF and a 380 Ohm Thevenin equivalent).
17. An initial 200 μ s pause and 8 \overline{RAS} -containing cycles are required when exiting an extended period of bias without clocks. An extended period of time without clocks is defined as one that exceeds the specified Refresh Interval.

16256L-11

The diagram illustrates the timing relationships for the RAS, UCAS, LCAS, and ADDRESS signals. The signals are shown as digital waveforms. The RAS signal is active-low, indicated by a bar over the label. The UCAS and LCAS signals are also active-low. The ADDRESS signal is shown with a hatched pattern during the valid period. The timing parameters are defined as follows:

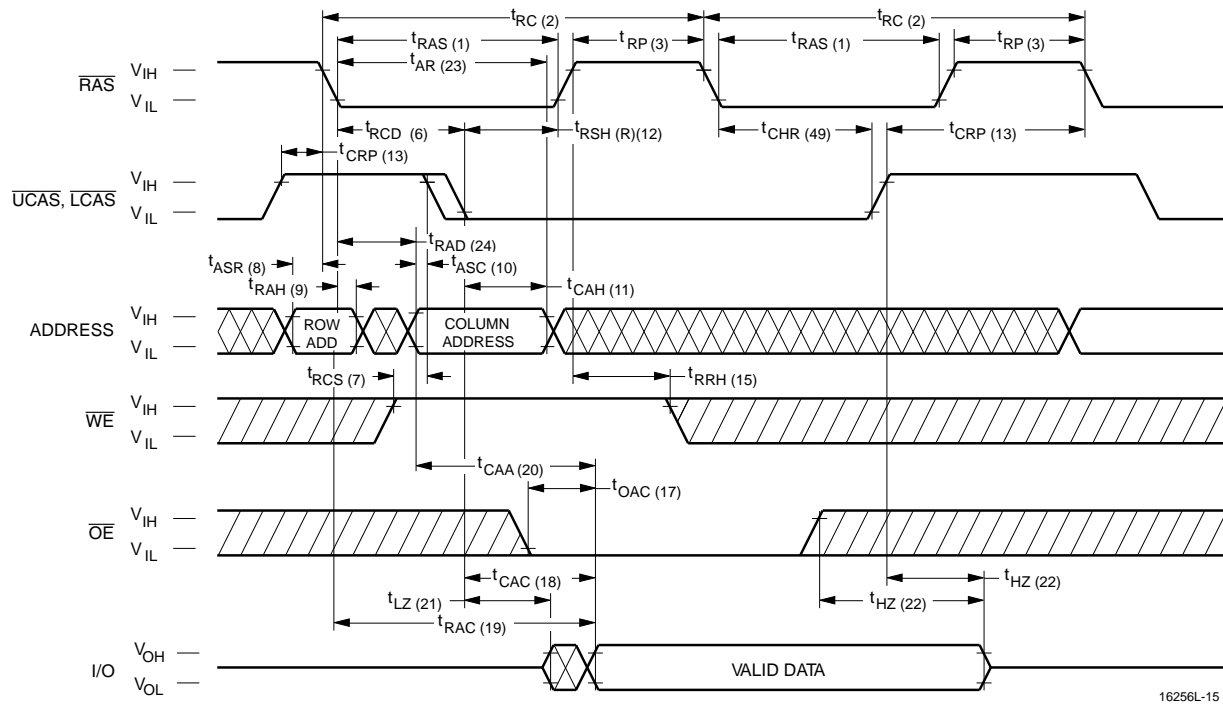

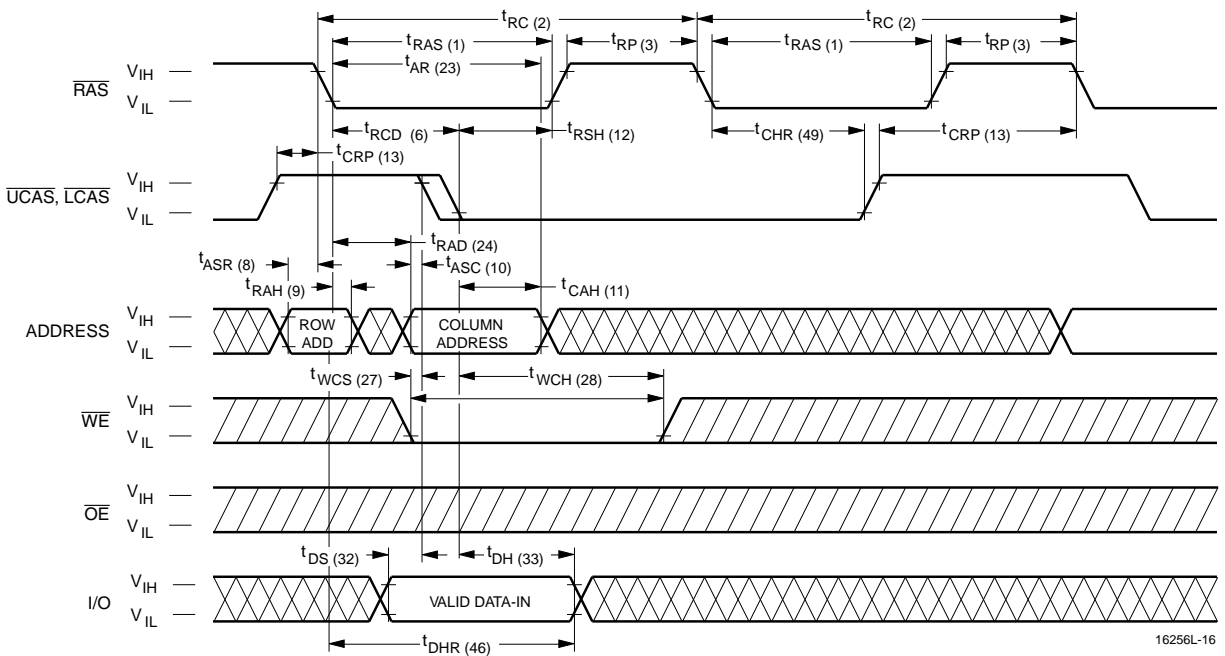

- $t_{RAS} (1)$: RAS access time, from the falling edge of RAS to the data becoming valid.
- $t_{RC} (2)$: RAS to column address strobe time, from the falling edge of RAS to the falling edge of UCAS/LCAS.
- $t_{RP} (3)$: RAS precharge time, from the rising edge of RAS to the data becoming invalid.
- $t_{CRP} (13)$: RAS to column address strobe precharge time, from the falling edge of RAS to the falling edge of UCAS/LCAS.
- $t_{AS} (8)$: Address setup time, from the falling edge of RAS to the data becoming valid.
- $t_{RA} (9)$: Address retention time, from the falling edge of RAS to the data becoming invalid.

Functional Description

The V53C16256L is a CMOS dynamic RAM optimized for high data bandwidth, low power applications. It is functionally similar to a traditional dynamic RAM. The V53C16256L reads and writes data by multiplexing an 18-bit address into a 9-bit row and a 9-bit column address. The row address is latched by the Row Address Strobe ($\overline{\text{RAS}}$). The column address "flows through" an internal address buffer and is latched by the Column Address Strobe ($\overline{\text{CAS}}$). Because access time is primarily dependent on a valid column address rather than the precise time that the $\overline{\text{CAS}}$ edge occurs, the delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ has little effect on the access time.

Memory Cycle

A memory cycle is initiated by bringing $\overline{\text{RAS}}$ low. Any memory cycle, once initiated, must not be ended or aborted before the minimum t_{RAS} time has expired. This ensures proper device operation and data integrity. A new cycle must not be initiated until the minimum precharge time $t_{\text{RP}}/t_{\text{CP}}$ has elapsed.

Read Cycle

A Read cycle is performed by holding the Write Enable ($\overline{\text{WE}}$) signal High during a $\overline{\text{RAS}}/\overline{\text{CAS}}$ operation. The column address must be held for a minimum specified by t_{AR} . Data Out becomes valid only when t_{OAC} , t_{RAC} , t_{CAA} and t_{CAC} are all satisfied. As a result, the access time is dependent on the timing relationships between these parameters. For example, the access time is limited by t_{CAA} when t_{RAC} , t_{CAC} and t_{OAC} are all satisfied.

Write Cycle

A Write Cycle is performed by taking $\overline{\text{WE}}$ and $\overline{\text{CAS}}$ low during a $\overline{\text{RAS}}$ operation. The column address is latched by $\overline{\text{CAS}}$. The Write Cycle can be $\overline{\text{WE}}$ controlled or $\overline{\text{CAS}}$ controlled depending on whether $\overline{\text{WE}}$ or $\overline{\text{CAS}}$ falls later. Consequently, the input data must be valid at or before the falling edge of $\overline{\text{WE}}$ or $\overline{\text{CAS}}$, whichever occurs last. In the $\overline{\text{CAS}}$ -controlled Write Cycle, when the leading edge of $\overline{\text{WE}}$ occurs prior to the $\overline{\text{CAS}}$ low transition, the I/O data pins will be in the High-Z state at the beginning of the Write function. Ending the Write with $\overline{\text{RAS}}$ or $\overline{\text{CAS}}$ will maintain the output in the High-Z state.

In the $\overline{\text{WE}}$ controlled Write Cycle, $\overline{\text{OE}}$ must be in the high state and t_{OED} must be satisfied.

Fast Page Mode Operation

Fast Page Mode operation permits all 512 columns within a selected row of the device to be randomly accessed at a high data rate. Maintaining $\overline{\text{RAS}}$ low while performing successive $\overline{\text{CAS}}$ cycles retains the row address internally and eliminates the need to reapply it for each cycle. The column address buffer acts as a transparent or flow-through latch while $\overline{\text{CAS}}$ is high. Thus, access begins from the occurrence of a valid column address rather than from the falling edge of $\overline{\text{CAS}}$, eliminating t_{ASC} and t_{T} from the critical timing path. $\overline{\text{CAS}}$ latches the address into the column address buffer and acts as an output enable. During Fast Page Mode operation, Read, Write, Read-Modify-Write or Read-Write-Read cycles are possible at random addresses within a row. Following the initial entry cycle into Fast Page Mode, access is t_{CAA} or t_{CAP} controlled. If the column address is valid prior to the rising edge of $\overline{\text{CAS}}$, the access time is referenced to the $\overline{\text{CAS}}$ rising edge and is specified by t_{CAP} . If the column address is valid after the rising $\overline{\text{CAS}}$ edge, access is timed from the occurrence of a valid address and is specified by t_{CAA} . In both cases, the falling edge of $\overline{\text{CAS}}$ latches the address and enables the output.

Fast Page Mode provides a sustained data rate of 43 MHz for applications that require high data rates such as bit-mapped graphics or high-speed signal processing. The following equation can be used to calculate the maximum data rate:

$$\text{Data Rate} = \frac{512}{t_{\text{RC}} + 511 \times t_{\text{PC}}}$$

Data Output Operation

The V53C16256L Input/Output is controlled by $\overline{\text{OE}}$, $\overline{\text{CAS}}$, $\overline{\text{WE}}$ and $\overline{\text{RAS}}$. A $\overline{\text{RAS}}$ low transition enables the transfer of data to and from the selected row address in the Memory Array. A $\overline{\text{RAS}}$ high transition disables data transfer and latches the output data if the output is enabled. After a memory cycle is initiated with a $\overline{\text{RAS}}$ low transition, a $\overline{\text{CAS}}$ low transition or $\overline{\text{CAS}}$ low level enables the internal I/O path. A $\overline{\text{CAS}}$ high transition or a $\overline{\text{CAS}}$ high level disables the I/O path and the output driver if it is enabled. A $\overline{\text{CAS}}$ low transition while $\overline{\text{RAS}}$ is high has no effect on the I/O data path or on the output drivers. The output drivers, when otherwise enabled, can be disabled by holding $\overline{\text{OE}}$ high. The $\overline{\text{OE}}$ signal has no effect on any data stored in the output latches. A $\overline{\text{WE}}$ low level can also disable the output drivers when $\overline{\text{CAS}}$ is low. During a Write cycle, if $\overline{\text{WE}}$

goes low at a time in relationship to $\overline{\text{CAS}}$ that would normally cause the outputs to be active, it is necessary to use $\overline{\text{OE}}$ to disable the output drivers prior to the $\overline{\text{WE}}$ low transition to allow Data In Setup Time (t_{DS}) to be satisfied.

Power-On

After application of the V_{CC} supply, an initial pause of 200 μs is required followed by a minimum of 8 initialization cycles (any combination of cycles containing a RAS clock). Eight initialization cycles are required after extended periods of bias without clocks (greater than the Refresh Interval).

During Power-On, the V_{CC} current requirement of the V53C16256L is dependent on the input levels of RAS and $\overline{\text{CAS}}$. If RAS is low during Power-On, the device will go into an active cycle and I_{CC} will exhibit current transients. It is recommended that RAS and $\overline{\text{CAS}}$ track with V_{CC} or be held at a valid V_{IH} during Power-On to avoid current surges.

Table 1. V53C16256L Data Output
Operation for Various Cycle Types

Cycle Type	I/O State
Read Cycles	Data from Addressed Memory Cell
$\overline{\text{CAS}}$ -Controlled Write Cycle (Early Write)	High-Z
$\overline{\text{WE}}$ -Controlled Write Cycle (Late Write)	$\overline{\text{OE}}$ Controlled. High $\overline{\text{OE}}$ = High-Z I/Os
Read-Modify-Write Cycles	Data from Addressed Memory Cell
Fast Page Mode Read	Data from Addressed Memory Cell
Fast Page Mode Write Cycle (Early Write)	High-Z
Fast Page Mode Read-Modify-Write Cycle	Data from Addressed Memory Cell
RAS-only Refresh	High-Z
$\overline{\text{CAS}}$ -before-RAS Refresh Cycle	Data remains as in previous cycle
$\overline{\text{CAS}}$ -only Cycles	High-Z
