# **256KB and 512KB BurstRAM™ Secondary Cache Modules for PowerPC™ PReP/CHRP Platforms**

**MPC2104  
MPC2105  
MPC2106  
MPC2107**

The MPC2104/5/6/7 are designed to provide burstable, high performance L2 cache for the PowerPC 60x microprocessor family in conformance with the PowerPC Reference Platform (PReP) and the PowerPC Common Hardware Reference Platform (CHRP) specifications. These products utilize synchronous or asynchronous data RAMs.

The MPC2104, MPC2105, and MPC2106 utilize synchronous BurstRAMs. The modules are configured as 32K x 72, 64K x 72, and 128K x 72 bits in a 182 (91 x 2) pin DIMM format. The MPC2104 uses four of Motorola's 5 V 32K x 18; the MPC2105 uses four of the 5 V 64K x 18; the MPC2106 uses eight of the 5 V 64K x 18. For tag bits, a 5 V cache tag RAM configured as 16K x 12 for tag field plus 16K x 2 for valid and dirty status bits is used.

Bursts can be initiated with the ADS signal. Subsequent burst addresses are generated internal to the BurstRAM by the CNTEN signal.

Write cycles are internally self timed and are initiated by the rising edge of the clock (CLKx) inputs. Eight write enables are provided for byte write control.

The MPC2107 utilizes asynchronous data RAMs. The module is configured as 32K x 64 in the same 182 pin DIMM format. Again, 5 V cache tag RAMs configured as 16K x 12 for tag field plus 16K x 2 for valid and dirty status bits are used. Burst capability is provided in that two burst addresses bypass the address latch.

Presence detect pins are available for auto configuration of the cache control. A serial EEPROM is optional to provide more in-depth description of the cache module. This EEPROM will be available on future revisions of the module family.

The module family pinout will support 5 V and 3.3 V components for a clear path to lower voltage and power savings. Both power supplies must be connected.

All of these cache modules are plug and pin compatible with each other.

NOTE: Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to RECOMMENDED OPERATING CONDITIONS. Exposure to higher than recommended voltages for extended periods of time could affect device reliability.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit.

This BiCMOS memory circuit has been designed to meet the dc and ac specifications shown in the tables, after thermal equilibrium has been established.

This device contains circuitry that will ensure the output devices are in High–Z at power up.

#### NOTES:

1. In setup and hold times, W (write) refers to either one or both byte write enables LW and UW.
2. All read and write cycle timings are referenced from CLK or COE.
3. COE is a don't care when UW or LW is sampled low.
4. Maximum access times are guaranteed for all possible PowerPC external bus cycles.
5. This is a synchronous device. All addresses must meet the specified setup and hold times for **ALL** rising edges of CLK whenever TSP or TSC is low, and the chip is selected. All other synchronous inputs must meet the specified setup and hold times for **ALL** rising edges of CLK when the chip is enabled. Chip enable must be valid at each rising edge of clock for the device (when TSP or TSC is low) to remain enabled.
6. 5 ns of set–up delay is incurred in address buffers.
7. Applies to MPC2104, MPC2105, and MPC2106.

5. Transition is measured  $\pm 500\text{ mV}$  from steady-state voltage with load of Figure 1B.
6. This parameter is sampled and not 100% tested.
7. Device is continuously selected ( $E = V_{IL}$ ,  $COE0 = V_{IL}$ ).
8. Applies to MPC2107.

### ASYNCHRONOUS READ CYCLE 1 (See Note 7)

**NOTES:**

1. A write occurs during the overlap of  $\overline{E}_{low}$  and  $\overline{W}_{low}$ .
2. If  $\overline{E}$  goes low coincident with or after  $\overline{W}$  goes low, the output will remain in a high impedance state.
3. All timings are referenced from the last valid address to the first transitioning address.
4. If  $\overline{E} \geq V_{IH}$ , the output will remain in a high impedance state.
5. At any given voltage and temperature,  $t_{WLQZ}$  (max) is less than  $t_{WHQX}$  (min), both for a given device and from device to device.

**ASYNCHRONOUS WRITE CYCLE 1 ( $\overline{W}$  Controlled, See Notes 1 and 2)**

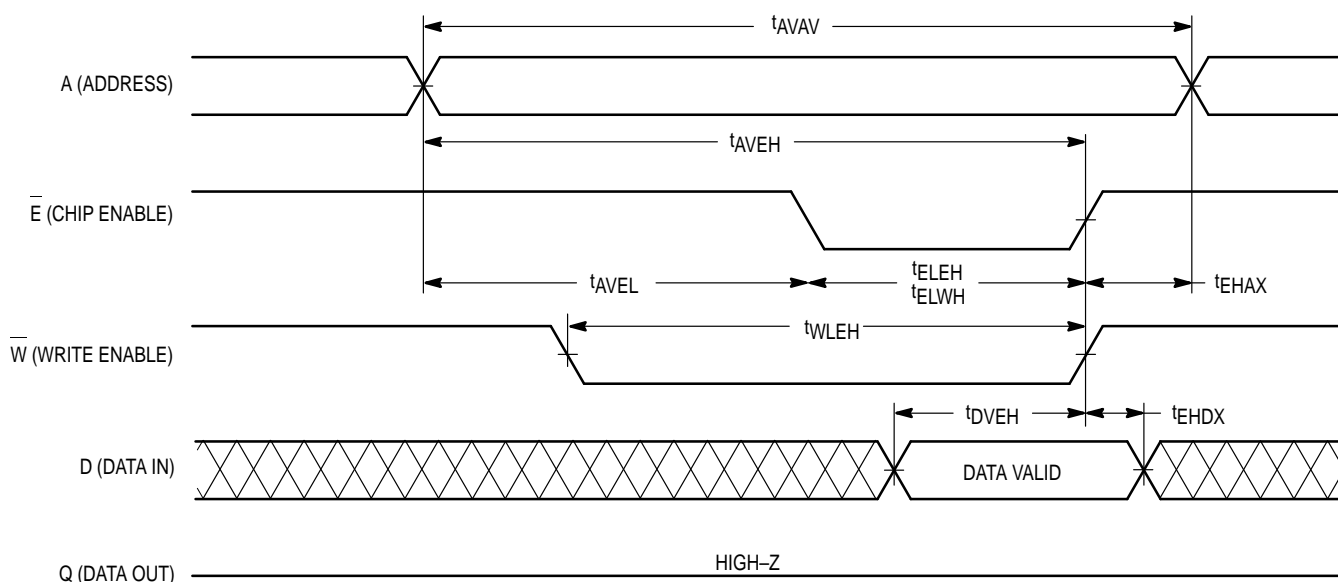

# **ASYNCHRONOUS DATA RAMs WRITE CYCLE 2** ( $\overline{E}$ Controlled, See Notes 1 and 2)

Parameter	Symbol	MPC2107-15		Unit	Notes
		Min	Max		
Write Cycle Time	$t_{AVAV}$	15	—	ns	0
Address Setup Time	$t_{AVEL}$	0	—	ns	
Address Valid to End of Write	$t_{AVEH}$	12	—	ns	
Enable to End of Write	$t_{ELEH}$ $t_{ELWH}$	10	—	ns	3, 4
Data Valid to End of Write	$t_{DVEH}$	7	—	ns	
Data Hold Time	$t_{EHDX}$	0	—	ns	
Write Recovery Time	$t_{EHAX}$	0	—	ns	

## NOTES:

1. A write occurs during the overlap of  $\overline{E}$  low and  $\overline{W}$  low.
2. All timings are referenced from the last valid address to the first transitioning address.
3. If  $\overline{E}$  goes low coincident with or after  $\overline{W}$  goes low, the output will remain in a high impedance state.
4. If  $\overline{E}$  goes high coincident with or before  $\overline{W}$  goes high, the output will remain in a high impedance state.

## TIMING LIMITS

The table of timing values shows either a minimum or a maximum limit for each parameter. Input requirements are specified from the external system point of view. Thus, address setup time is shown as a minimum since the system must supply at least that much time (even though most devices do not require it). On the other hand, responses from the memory are specified from the device point of view. Thus, the access time is shown as a maximum since the device never provides data later than that time.
