

## LH0045/LH0045C Two Wire Transmitter

### General Description

The LH0045/LH0045C Two Wire Transmitters are linear integrated circuits designed to convert the voltage from a sensor to a current, and send it through to a receiver, utilizing the same simple twisted pair as the supply voltage.

The LH0045 and LH0045C contain an internal reference designed to power the sensor bridge, a sensitive input amplifier, and an output current source. The output current scale can be adjusted to match the industry standards of 4.0 mA to 20 mA or 10 mA to 50 mA.

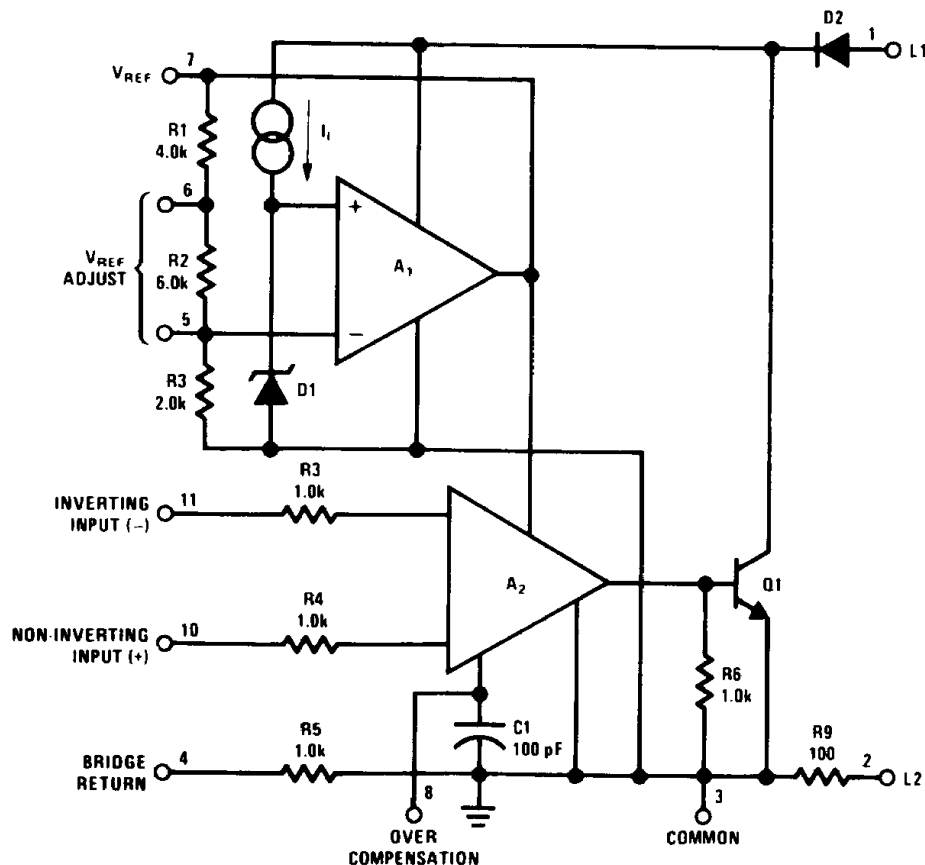

Designed for use with various sensors, the LH0045/LH0045C will interface with thermocouples, strain gauges, or thermistors. The use of the power supply leads as the signal output eliminates two or three extra wires in remote signal applications. Also, current output minimizes susceptibility to voltage noise spikes and eliminates line drop problems.

The LH0045/LH0045C is intended to fulfill a wide variety of process control, instrumentation, and data acquisition applications. The LH0045 is guaranteed over the temperature range of  $-55^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ ; whereas the LH0045C is guaranteed from  $-25^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ .

### Features

- High sensitivity  $> 10 \mu\text{A}/\mu\text{V}$
- Low input offset voltage 1.0 mV
- Low input bias current 2.0 nA
- Single supply operation 10V to 50V
- Programmable bridge reference (LH0045G) 5.0V to 30V
- Non-interactive span and null adjust
- Over compensation capability
- Supply reversal protection

### Equivalent Schematic

\*Note: Pins shown are for the 12 pin to 8 ("G") package.

TL/K/5556-1

## Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications. (Note 2)

## Applications Information

### CIRCUIT DESCRIPTION AND OPERATION

A simplified schematic of the LH0045/LH0045C is shown in Figure 1. Differential amplifier,  $A_2$  converts very low level signals to an output current via transistor  $Q_1$ . Reference voltage diode  $D_1$  is used to supply voltage for operation of  $A_2$  and to bias an external bridge. Current source  $I_1$  minimizes fluctuation in the bridge reference voltage due to changes in  $V_S$ .

In normal operation, the LH0045/LH0045C is used in conjunction with an external bridge comprised of  $R_{B1}$  through  $R_{B4}$ . The bridge resistors in conjunction with bridge return resistor,  $R_5$ , bias  $A_2$  in its linear region and sense the input signal; e.g.  $R_{B4}$  might be a strain sensitive resistor in a strain gauge bridge.  $R_T$  is adjusted to purposely unbalance the bridge for 4.0 mA output (null) for zero signal input. This is accomplished by forcing  $2.5 \mu A$  more through  $R_{B3}$  than  $R_{B4}$ .

The  $2.5 \mu A$  imbalance causes a voltage rise of  $(2.5 \mu A) \times (100\Omega)$  or  $250 \mu V$  at the top of  $R_{B3}$ . Terminal L2 may be viewed as the output of an op amp whose closed loop gain is approximately  $R_F/R_{B3} = 1600$ .

The  $250 \mu V$  rise at the top of  $R_{B3}$  causes a voltage drop of  $(1600) \times (250 \mu V)$  or  $-0.4V$  across  $R_9$ . An output current,  $I_S$ , equal to  $0.4V/R_9$  or  $4.0$  mA is thus established in  $Q_1$ . If  $R_{B4}$  is now decreased by  $1.0\Omega$  (due to application of a strain force), a  $-1.0$  mV change in input voltage will result. This causes L2 to drop to  $-2.0V$ . The output current would then be  $2.0V/100\Omega$  or  $20$  mA (Full Scale). If  $R_{B3}$  is a resistor of the same material as  $R_{B4}$  but not subjected to the strain, temperature drift effects will be equal in the two legs and will cancel.

In actual practice the loading effects of  $R_{B2}$  on the gain (span) and  $R_F$  on output current must be taken into account.

### THERMAL CONSIDERATIONS

The power output transistor of the LH0045 is thermally isolated from the signal amplifier,  $A_2$ . Nevertheless, a change in the power dissipation will cause a change in the temperature of the package and thus may cause amplifier drift. These temperature excursions may be minimized by careful heat sinking to hold the case temperature equal to the ambient. With the TO-8 (G) package this is best accomplished by a clip-on heat sink such as the Thermalloy #2240A or the Wakefield #215-CB. The case is electrically isolated from the circuit.

In addition, the power change can be minimized by operating the device from relatively high supply voltages in series with a relatively high load resistance. When the signal forces the supply current higher, the voltage across the device will be reduced and the internal power dissipation kept nearly equal to the low current, high voltage condition.

For example, take the case of a  $4.0$  mA to  $20$  mA transmitter with a  $24V$  supply and a  $100\Omega$  load resistance. The power at  $4.0$  mA is  $(23.6V) \times (4.0$  mA) =  $94.4$  mW while at full scale the power is  $(22V) \times (20$  mA) =  $440$  mW. The net change in power is  $345$  mW. This change in power will cause a change in temperature and thus a change in offset voltage of  $A_2$ .

If the optimum load resistance of  $800\Omega$  (from Figure 2) is used, the power at null is  $[24V - (4.0$  mA)  $\times (800\Omega)]$   $(4.0$  mA) =  $83$  mW. The power at full scale is  $[24V - (20$  mA)  $\times (800\Omega)]$   $(20$  mA) =  $160$  mW. The net change is  $77$  mW. This change is significantly less than without the resistor.

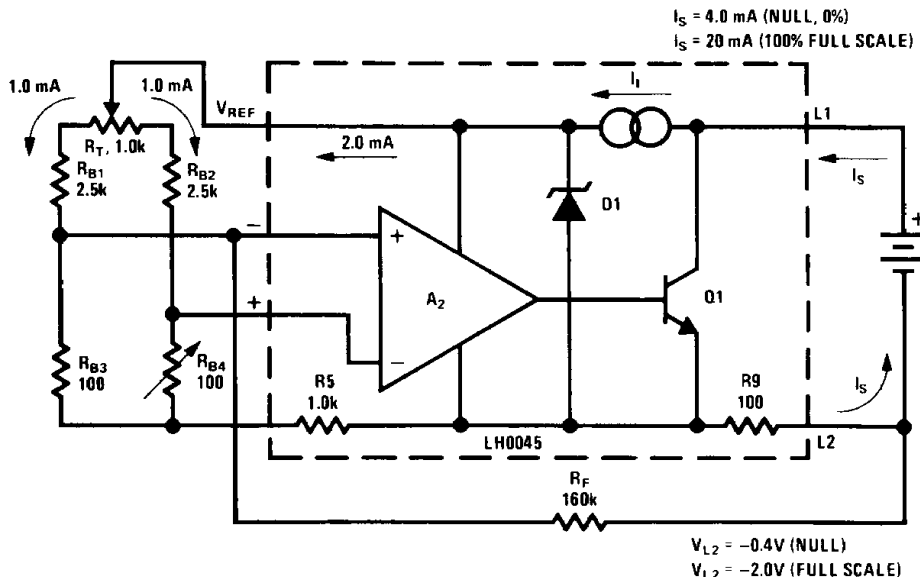

FIGURE 1. LH0045 Simplified Schematic

TL/K/5556-9

## Applications Information (Continued)

If the supply voltage is increased to 48V and the load resistance chosen to be the optimum value from *Figure 2* (1.95k), then the power at null is  $[48V - (4.0 \text{ mA}) \times (1.95k)] (4.0 \text{ mA}) = 160.8 \text{ mW}$  and the power at full scale is  $[48 - (20) \times (1.95k)] (20 \text{ mA}) = 180 \text{ mW}$  for a net change of 19.2 mW.

TL/K/5556-10

**FIGURE 2. Optimum Load Resistance vs Supply Voltage**

Note that the optimized load resistance is actually the sum of the line resistance, receiver resistances and added external load resistance. However, in many applications the line resistance and receiver resistances are negligible compared to the added external load resistance and thus may be omitted in calculations.

### AUXILIARY PINS

The LH0045 has several auxiliary pins designed to provide the user with enhanced flexibility and performance. The following is a discussion of possible uses for these pins.

#### Programmable $V_{REF}$ —Pins 5 and 6

The LH0045G provides pins 5 and 6 to allow the user to program the value of the reference voltage. The factory trimmed 10V value is obtained by leaving 5 and 6 open. A short between 5 and 6 will program the reference to a nominal 5.1V.

A resistor or pot may be placed between pin 5 and common (pin 3) to obtain reference voltages between 10V and 30V or between pin 5 and pin 7 for reference voltages below 10V. Increased reference voltage might be useful to extend the positive common mode range or to accommodate transducers requiring higher supply voltage. A plot of resistance between pin 5 and pin 3 versus  $V_{REF}$  is given in the typical electrical characteristics section.  $V_{REF}$  may be adjusted about its nominal value by arranging a pot from  $V_{REF}$  to common and feeding a resistor from the wiper into pin 5 so that it may either inject or extract current. Lastly, pin 5 may be used as a nominal 1.7V reference point, if care is taken not to unduly load it with either DC current or capacitance. Obviously, higher supply voltages must be used to obtain the higher reference values. The minimum supply voltage to reference voltage differential is about 4.0V.

### Bridge Return

An applications resistor is provided in the LH0045 with a nominal value of 1.0 kΩ. The primary application for the resistor is to maintain the minimum common mode input voltage (1.0V) required by the signal amplifier,  $A_2$ . A typical input application might utilize a strain gauge or thermistor bridge where the resistance of the sensor is 100Ω. Since only 1.0 mA may be drawn from  $V_{REF}$ , the 1.0 kΩ bridge return resistor is used to bias  $A_2$  in its linear region as shown in *Figure 3*.

TL/K/5556-11

**FIGURE 3. Use of Bridge Return**

#### Over Compensation—Pin 8

Over compensation of the signal amplifier,  $A_2$ , may be desirable in DC applications where the noise-bandwidth must be minimized. A capacitor should be placed between pin 8 and pin 3, common.

Typically,

$$f_{3 \text{ db}} = \frac{1}{2 \pi R (C_1 + C_{EXT})}$$

where:

$R = 400 \text{ M}\Omega$

$C_1 = \text{Internal Compensation Capacitor} = 100 \text{ pF}$

$C_{EXT} = \text{External (overcompensation) Capacitor}$

#### Input Guard—Pins 9 and 12

Pins 9 and 12 have no internal connection whatever and thus need not be used. In some critical low current applications there may be an advantage to running a guard conductor between the inputs and the adjacent pins to intercept stray leakage currents. Pins 9 and 12 may be connected to this guard to simplify the PC board layout and allow the guard to continue under the device. (See AN-63 for further discussion of guarding techniques.)

#### NULL AND SPAN ADJUSTMENTS

Most applications of the LH0045 will require potentiometers to trim the initial tolerances of the sensor, the external resistors and the LH0045 itself. The preferred adjustment proce-

## Applications Information (Continued)

ture is to stimulate the sensor, alternating between two known values, such as zero and full scale. The span and null are adjusted by monitoring the output current on a chart recorder, meter, or oscilloscope. A full scale stimulus is applied to the sensor and the span potentiometer adjusted for the desired full scale. Then, to adjust the null, apply a zero percent signal to the sensor and adjust the null potentiometer for the desired zero percent current indication.

If it is impractical to cycle the sensor during the calibration procedure, the signal may be simulated electrically with two cautions: 1) the calibration signal must be floating and 2) the calibration thus achieved does not account for sensor inaccuracies and/or errors in the signal generator.

### SENSOR SELECTION

Generally it is easiest to use an insulated sensor. If it is necessary to use a grounded sensor, the power supply must be isolated from chassis ground to avoid extraneous circulating currents.

### DESIGN EXAMPLE

There are numerous circuit configurations that may be utilized with the LH0045. The following is intended as a general design example which may be extended to specific cases.

#### Circuit Requirements

##### Output Characteristics

- a. 0% = 4.0 mA (NULL)
- b. 100% = 20 mA (SPAN = 16 mA)
- c. Supply Voltage = 24V

##### Input (Sensor) Characteristics

- a.  $V_{IN} = 100$  mV (Full Scale)
- b.  $V_{IN} = 0$  mV (Zero Scale)
- c. Source Impedance  $\leq 1.0\Omega$

##### General Characteristics

- a.  $0^\circ\text{C} \leq T_A \leq +75^\circ\text{C}$
- b. Overall Accuracy  $\leq 0.5\%$

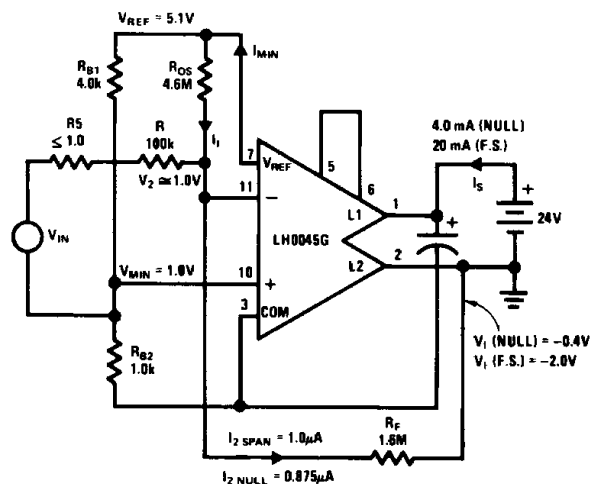

FIGURE 4. Design Example Circuit

### Selection of $R_F$

Input bias current to the LH0045C is guaranteed less than 10 nA. Furthermore, the change in  $I_B$  over the temperature range of interest is typically under 1.0 nA. If  $I_2$  SPAN is selected to be 1.0  $\mu\text{A}$  (1000  $\Delta I_B$ ) errors due to  $\Delta I_B/\Delta T$  will be less than 0.1%. For SPAN = 16 mA.

$$V_{SPAN} = \Delta V_1 = -(16 \text{ mA})(R_9) = -1.6 \text{ V}$$

where  $R_9$  = Internal Current Set Resistor =  $100\Omega$ .

For  $I_2$  SPAN = 1.0  $\mu\text{A}$ ,

$$R_F = \frac{V_{SPAN}}{I_2 \text{ SPAN}} = \frac{-1.6 \text{ V}}{1.0 \mu\text{A}} = 1.6 \text{ M}\Omega$$

$$R_F = 1.6 \text{ M}\Omega$$

**Note:** For applications with DC gain (ratio of feedback and input resistance) less than 8, it is recommended that a Schottky barrier diode be connected between pin 11 (cathode) and pin 3 (anode). This prevents the possibility of latch up resulting from the inverting input being forced beyond the amplifier supply voltage during power up.

### Selection of $R_{B1}$ and $R_{B2}$

The minimum input common mode voltage,  $V_{MIN}$  required at the pin 10 input of  $A_2$  is 1.0V. Furthermore, the maximum open loop supply current ( $I_{SOL}$ ) drawn by the LH0045 is 3.0 mA. That leaves  $I_{MIN} = 4.0 \text{ mA} - 3.0 \text{ mA} = 1.0 \text{ mA}$  left to bias the bridge at null. Hence:

$$R_{B2} \geq \frac{V_{MIN}}{I_{MIN}} = \frac{1.0 \text{ V}}{1.0 \text{ mA}} = 1.0 \text{ k}\Omega$$

And,

$$\frac{V_{REF} R_{B2}}{R_{B1} + R_{B2}} = 1.0 \text{ V}$$

$$R_{B1} = R_{B2} \frac{V_{REF} - 1.0 \text{ V}}{1.0 \text{ V}}$$

$$= 1.0 \text{ k}\Omega (5.1 - 1.0)$$

$$R_{B1} \cong 4.0 \text{ k}\Omega$$

Alternatively, an LM113, 1.22V reference diode, or an op amp such as the LM108 may be used to bias the signal amplifier,  $A_2$ , as shown in Figure 5. These techniques have the advantage of lowering the impedance seen at pin 10.

### Selection of $R_{O5}$

$R_{O5}$  is selected to provide the null current of 4.0 mA,  $V_1 \text{ NULL} = 4.0 \text{ mA} \times 100\Omega = 0.4 \text{ V}$ . From previous calculations we know that  $V_{MIN} = 1.0 \text{ V}$ . The voltage pin 11,  $V_2$  is:

$$V_2 = V_{MIN} + V_{OS} \cong V_{MIN}$$

for  $V_{IN} = 0 \text{ V}$

Hence, the current required to generate the null voltage,  $I_2 \text{ NULL}$  is:

$$I_2 \text{ NULL} = \frac{V_{MIN} - V_1 \text{ NULL}}{R_F}$$

$$= \frac{1.0 \text{ V} - (-0.4 \text{ V})}{1.6 \text{ M}\Omega} = 0.875 \mu\text{A}$$

This current must be provided by  $R_{O5}$  from  $V_{REF}$ ; hence:

$$R_{O5} = \frac{V_{REF} - V_{MIN}}{I_2 \text{ NULL}}$$

## Applications Information (Continued)

TL/K/5556-13

FIGURE 5. Alternate Biasing Techniques

The nominal value for  $V_{REF}$  is 5.1V, therefore the nominal value for  $R_{OS}$  is:

$$\frac{5.1V - 1.0V}{0.875 \mu A} \text{ or}$$

$$R_{OS} = 4.6 M\Omega$$

It should be noted however, that the variation of  $V_{REF}$  may be as high as 5.9V or as low as 4.3V. Furthermore, the tolerances of  $R_9$  (100 $\Omega$ ),  $R_{B1}$ ,  $R_{B2}$ , and the input  $V_{OS}$  of  $A_2$  would predict values for  $R_{OS}$  as low as 3.98M and as high as 5.43M. The implication is that in the specific case,  $R_{OS}$  should be implemented with a pot, of appropriate value, in order to accommodate the tolerances of  $V_{REF}$ ,  $R_9$ ,  $V_{OS}$ ,  $R_{B1}$ ,  $R_{B2}$ , etc.

**Selection of R**

SPAN is required to be 16 mA. From feedback theory and the gain equation we know:

$$I_{SPAN} = V_{IN} \frac{R_F}{R} \times \frac{1}{R_9}$$

where:

$R$  = Total impedance in signal path between pin 10 and pin 11

$R_9$  = Current setting resistor = 100 $\Omega$

$V_{IN}$  = Full scale input voltage = 100 mV

$$\therefore R = \frac{(V_{IN}) (R_F)}{(I_{SPAN}) (R_9)}$$

$$R = \frac{(100 \text{ mV}) (1.6 M\Omega)}{(16 \text{ mA}) (100\Omega)}$$

$$R = 100 \text{ k}\Omega$$

As before, uncertainties in device parameters might dictate that  $R_F$  be made a pot of appropriate value.

**Summary of the Steps to Determine External Resistor Values**

1. Select  $I_{FULL \text{ SCALE}} = I_{NULL} + I_{SPAN}$  for the desired application. ( $I_{NULL}$  is frequently 4.0 mA and  $I_{FULL \text{ SCALE}}$  is frequently 20 mA.)

TL/K/5556-14

2. Select  $I_2 \text{ SPAN}$  so that it is large compared to  $\Delta I_B$ . 1000  $\Delta I_B$  is a good value.
3. Determine  $V_{SPAN} = \Delta V_2 = (I_{SPAN}) (R_9)$ .
4. Determine  $R_F = (V_{SPAN}/I_2 \text{ SPAN})$
5. Select

$$R_{B2} \geq \frac{V_{MIN}}{I_{MIN}}$$

$$R_{B2} \geq \frac{1V}{I_{NULL} - I_{SOL}}$$

Where:

$V_{MIN}$  = minimum common mode input voltage

$I_{MIN}$  = minimum available bridge current

$I_{SOL}$  = maximum open loop supply current

6. Determine

$$R_{B1} = R_{B2} \frac{V_{REF} - V_{MIN}}{V_{MIN}}$$

7. Determine  $V_2 \text{ NULL} = I_{NULL} R_9$
8. Determine

$$I_2 \text{ NULL} = \frac{V_{MIN} - V_2 \text{ NULL}}{R_F}$$

9. Determine

$$R_{OS} = \frac{V_{REF} - V_{MIN}}{I_2 \text{ NULL}}$$

10. Determine

$$R = \frac{(V_{IN}) (R_F)}{(I_{SPAN}) (R_9)}$$

Where:

$V_{IN}$  = Sensor full scale output voltage

## Applications Information (Continued)

### ERROR BUDGET ANALYSIS

#### Errors Due to Change in $V_{REF}$ ( $\Delta V_{REF}$ )

There are several factors which could cause a change in  $V_{REF}$ . First, as the ambient temperature changes, a  $V_{REF}$  drift of  $\pm 0.2 \text{ mV}/^\circ\text{C}$  might be expected. Secondly, supply voltage variations could cause a  $0.5 \text{ mV/V}$  change in  $V_{REF}$ . Lastly, self-heating due to power dissipation variations can cause drift of the reference.

An overall expression for change in  $V_{REF}$  is:

$$\Delta V_{REF} = \underbrace{[(\theta)(\Delta P_{DISS}) + \Delta T_A] \frac{\Delta V_{REF}}{\Delta T}}_{\text{Thermal Effects}} + \underbrace{\frac{\Delta V_{REF}}{\Delta V_S} (\Delta V_S)}_{\text{Supply Voltage Effects}}$$

Where:

$\theta$  = Thermal resistance, either junction-to-ambient or junction-to-case

$\Delta P_{DISS}$  = Change in avg. power dissipation

$\Delta T_A$  = Change in ambient temperature

$\frac{\Delta V_{REF}}{\Delta T}$  = Reference voltage drift (in  $\text{mV}/^\circ\text{C}$ )

$\frac{\Delta V_{REF}}{\Delta V_S}$  = Line regulation of  $V_{REF}$

Several steps may be taken to minimize the bracketed terms in the equation above. For example, operating the LH0045G with a heat sink reduces the thermal resistance from  $\theta_{JA} = 83^\circ\text{C}/\text{W}$  to  $\theta_{JC} = 60^\circ\text{C}/\text{W}$ . The  $\Delta P_{DISS}$  term may be significantly reduced using the power minimization technique described under "Thermal Considerations". For the design example,  $\Delta P_{DISS}$  is reduced from 384 mW to 77 mW ( $R_L = 800\Omega$ ). Evaluating the LH0045G with a heat sink and  $R_L = 800\Omega$  yields.

$$\Delta V_{REF} = \left( \frac{60^\circ\text{C}}{\text{W}} (0.077\text{W}) + 75^\circ\text{C} \right) \left( \frac{0.2 \text{ mV}}{^\circ\text{C}} \right) + \frac{0.5 \text{ mV}}{\text{V}} (16\text{V})$$

$$\Delta V_{REF} = 24 \text{ mV}$$

An expression for error in the output current due to  $\Delta V_{REF}$  is:

$$\frac{\Delta I_S}{I_{SPAN}} (\%) = 100 \frac{(K)(R_{OS})(\Delta V_{REF}) - (1-K)(\Delta V_{REF})(R_F)}{(R_9)(R_{OS})(I_{SPAN})}$$

Where:

$\Delta V_{REF}$  = Total change in  $V_{REF}$

$$K = \frac{R_{B2}}{R_{B1} + R_{B2}}$$

$R_9$  = Current set resistor

$I_{SPAN}$  = Change in output current from 0% to 100%

For example,  $\Delta V_{REF} = 24 \text{ mV}$ ,  $K = 0.2$ ,  $R_9 = 100\Omega$ ,  $I_{SPAN} = 16 \text{ mA}$ . Hence, a 0.12% worst case error might be expected in output currents due to  $\Delta V_{REF}$  effects.

#### Error Due to $V_{OS}$ Drift

One of the primary causes of error in  $I_S$  is caused by  $V_{OS}$  drift. Drift may be induced either by self heating of the device or ambient temperature changes. The input offset voltage drift,  $\Delta V_{OS}/\Delta T$ , is nominally  $3.3 \mu\text{V}/^\circ\text{C}$  per millivolt of initial offset. An expression for the total temperature dependent drift is:

$$\Delta V_{OS} = [(\theta)(\Delta P_{DISS}) + \Delta T_A] \frac{\Delta V_{OS}}{\Delta T}$$

Where:

$\theta$  = Thermal resistance either junction-to-ambient or junction-to-case

$\Delta P_{DISS}$  = Change in average power dissipation

$\Delta T_A$  = Change in ambient temperature

The bracketed term may be minimized by heat sinking and using the power minimization technique described under "Thermal Considerations". For the LH0045G design example,  $\Delta V_{OS} = 0.352 \text{ mV}$  under ambient conditions and  $0.263 \text{ mV}$  using a heat sink and  $R_L = 800\Omega$ .

The error in output current due to  $\Delta V_{OS}$  is:

$$\begin{aligned} \frac{\Delta I_S}{I_{SPAN}} (\text{in } \%) &= 100 \times \frac{\Delta V_{OS}}{V_{IN} (\text{FULL SCALE})} \\ &= 100 \times \frac{R_F}{(R)(R_9)(I_{SPAN})} \end{aligned}$$

For the design example,  $\Delta V_{OS} = 0.263 \text{ mV}$ ,  $V_{IN} (\text{Full Scale}) = 100 \text{ mV}$ . Hence,  $0.26 \text{ mV} \div 100 \text{ mV}$  or 0.26% worst case error could be expected in output current effects.

#### Errors Due to Changes in $R_9$

The temperature coefficient of  $R_9$  (TCR) will produce errors in the output current. Changes in  $R_9$  may be caused by self-heating of the device or by ambient temperature changes.

$$\frac{\Delta I_S}{I_{SPAN}} (\text{in } \%) = 100 \frac{\Delta R_9}{\Delta T} (\theta P_{DISS} + \Delta T_A)$$

Where:

$\theta$  = Thermal resistance either from junction-to-ambient or junction-to-case

$\Delta P_{DISS}$  = Change in average power dissipation

## Applications Information (Continued)

$\Delta T_A$  = Change in ambient temperature

$$\frac{\Delta R_9}{\Delta T} = \text{TCR of } R_9$$

Using the LH0045G design example,  $\Delta R_9/\Delta T = 0.03\%/^{\circ}\text{C}$ , hence a 3.2% worst case error in output current might be expected for operation without a heat sink over the temperature range.

Heat sinking the device and using  $R_L = 800\Omega$ , reduces  $\Delta I_S/I_{SPAN}$  to 2.3%.

The error analysis indicates that the internal current set resistor,  $R_9$ , is inadequate to satisfy high accuracy design criterion. In these instances, an external  $100\Omega$  resistor should be substituted for  $R_9$ .

Obviously, the TCR of the resistor should be low. Metal film or wire-wound resistors are the best choice offering TCR's less than 10 ppm/ $^{\circ}\text{C}$  versus 50 ppm/ $^{\circ}\text{C}$  typical drift for  $R_9$ .

### External Causes of Error

The components external to the LH0045 are also critical in determining errors. Specifically, the composition of resistors  $R_{B1}$ ,  $R_{OS}$ ,  $R_F$ ,  $R$ , etc. in the design example will influence both drift and long term stability.

In particular, resistors and potentiometers of wire wound construction are recommended. Also, metal-film resistors with low TCR ( $\leq 10$  ppm/ $^{\circ}\text{C}$ ) may be used for fixed resistor applications.

### Error Analysis Summary

The overall errors attributable to the LH0045 may be minimized using heat sinking, and utilization of an external load resistor. Although  $R_L$  reduces the compliance of the circuit, its use is generally advisable in precision applications. External components should be selected for low TCR and long term stability.

The design example errors, using an external  $100\Omega$  wire wound resistor for  $R_9$  equal:

$$\frac{\Delta I_S}{I_{SPAN}} = \underbrace{0.12\%}_{\Delta V_{REF}} + \underbrace{0.26\%}_{\Delta V_{OS}} + \underbrace{0.08\%}_{\Delta R_9} = 0.46\%$$

### SOCKETS AND HEAT SINKS

Mounting sockets, test sockets and heat sinks are available for the G package.

The following or their equivalents are recommended:

#### Sockets:

G — 12-Lead TO-8: Barnes Corp. #MGX-12  
Textool #212-100-323

#### Heat Sinks:

G — 12-Lead TO-8: Thermalloy #2240A  
Wakefield #215-CB

## Definition of Terms

**Input Offset Voltage,  $V_{OS}$ :** The voltage which must be applied between the input terminals through equal resistances to obtain 4.0 mA of supply (output) current.

**Input Bias Current,  $I_B$ :** The average of the two input currents.

**Input Offset Current,  $I_{OS}$ :** The difference in the current into the two input terminals when the supply (output) current is 4.0 mA.

**Input Resistance,  $R_{IN}$ :** The ratio of the change in input voltage to the change in input current at either input with the other input connected to 1.0  $V_{DC}$ .

**Open Loop Transconductance,  $g_{MOL}$ :** The ratio of the supply (output) current SPAN to the input voltage required to produce that SPAN.

**Open Loop Output Resistance,  $R_{OUT}$ :** The ratio of a specified supply (output) voltage change to the resulting change in supply (output) current at the specified current level.

**Common Mode Rejection Ratio, CMRR:** The ratio of the change in input offset voltage to the peak-to-peak input voltage range.

**Power Supply Rejection Ratio, PSRR:** The ratio of the change in input offset voltage to the change in supply (output) voltage producing it.

**Input Voltage Range,  $V_{IN}$ :** The range of voltages on the input terminals for which the device operates within specifications.

**Open Loop Supply Current,  $I_S$ :** The supply current required with the signal amplifier  $A_2$  biased off (inverting input positive, non-inverting input negative) and no load on the  $V_{REF}$  terminal.

This represents a measure of the minimum low end signal current.

**Reference Voltage Line Regulation,  $\Delta V_{REF}/\Delta V_S$ :** The ratio of the change in  $V_{REF}$  to the peak-to-peak change in supply (output) voltage producing it.

**Reference Voltage Load Regulation,  $\Delta V_{REF}/\Delta I_{REF}$ :** The change in  $V_{REF}$  for a stipulated change in  $I_{REF}$ .
