Hardware Manual

REJ09B0050-02000

Cautions

Keep safety first in your circuit designs!

1. Renesas Technology Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage.

Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corporation product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corporation or a third party.
2. Renesas Technology Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corporation or an authorized Renesas Technology Corporation product distributor for the latest product information before purchasing a product listed herein.
The information described here may contain technical inaccuracies or typographical errors.
Renesas Technology Corporation assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.
Please also pay attention to information published by Renesas Technology Corporation by various means, including the Renesas Technology Corporation Semiconductor home page (<http://www.renesas.com>).
4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corporation assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
5. Renesas Technology Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corporation or an authorized Renesas Technology Corporation product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
6. The prior written approval of Renesas Technology Corporation is necessary to reprint or reproduce in whole or in part these materials.
7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.
Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
8. Please contact Renesas Technology Corporation for further details on these materials or the products contained therein.

General Precautions on Handling of Product

1. Treatment of NC Pins

Note: Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

2. Treatment of Unused Input Pins

Note: Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

3. Processing before Initialization

Note: When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

4. Prohibition of Access to Undefined or Reserved Addresses

Note: Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

Configuration of This Manual

This manual comprises the following items:

1. General Precautions on Handling of Product
2. Configuration of This Manual
3. Preface
4. Contents
5. Overview
6. Description of Functional Modules

- CPU and System-Control Modules
- On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

7. List of Registers
8. Electrical Characteristics
9. Appendix
10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

Preface

The H8S/2368 Group are microcomputers (MCU) made up of the H8S/2600 CPU employing Renesas Technology's original architecture as their cores, and the peripheral functions required to configure a system.

The H8S/2600 CPU has an internal 32-bit configuration, sixteen 16-bit general registers, and a simple and optimized instruction set for high-speed operation. The H8S/2600 CPU can handle a 16-Mbyte linear address space.

This LSI is equipped with direct memory access controller (DMAC) and data transfer controller (DTC) bus masters, ROM and RAM memory, a 16-bit timer pulse unit (TPU), a programmable pulse generator (PPG), 8-bit timers (TMR), a watchdog timer (WDT), serial communication interfaces (SCI and IrDA), a 10-bit A/D converter, an 8-bit D/A converter, and I/O ports as on-chip peripheral modules required for system configuration. I²C bus interface 2 (IIC2) can also be included as an optional interface.

A high-functionality bus controller is also provided, enabling fast and easy connection of DRAM and other kinds of memory.

A single-power flash memory (F-ZTAT™) version is available for this LSI's ROM. This provides flexibility as it can be reprogrammed in no time to cope with all situations from the early stages of mass production to full-scale mass production. This is particularly applicable to application devices with specifications that will most probably change.

Note: F-ZTAT™ is a trademark of Renesas Technology Corp.

Target Users: This manual was written for users who will be using the H8S/2368 Group in the design of application systems. Target users are expected to understand the fundamentals of electrical circuits, logical circuits, and microcomputers.

Objective: This manual was written to explain the hardware functions and electrical characteristics of the H8S/2368 Group to the target users.
Refer to the H8S/2600 Series, H8S/2000 Series Programming Manual for a detailed description of the instruction set.

Notes on reading this manual:

- In order to understand the overall functions of the chip
Read the manual according to the contents. This manual can be roughly categorized into parts on the CPU, system control functions, peripheral functions and electrical characteristics.

- In order to understand the details of the CPU's functions
Read the H8S/2600 Series, H8S/2000 Series Programming Manual.
For the execution state of each instruction in this LSI, see Appendix D, Bus State during Execution of Instructions.
- In order to understand the details of a register when its name is known
Read the index that is the final part of the manual to find the page number of the entry on the register. The addresses, bits, and initial values of the registers are summarized in section 23, List of Registers.
Examples: Register name: The following notation is used for cases when the same or a similar function, e.g. 16-bit timer pulse unit or serial communication, is implemented on more than one channel: XXX_N (XXX is the register name and N is the channel number)
 Bit order: The MSB is on the left and the LSB is on the right.
 Number notation: Binary is B'xxxx, hexadecimal is H'xxxx, decimal is xxxx
 Signal notation: An overbar is added to a low-active signal: $\overline{\text{xxxx}}$

Related Manuals: The latest versions of all related manuals are available from our web site.
 Please ensure you have the latest versions of all documents you require.

21.2.1 Connecting a Crystal Oscillator	678	Description added in the 6th line. An AT-cut parallel-resonance type should be used. When a clock is supplied with a crystal resonator connected, the frequency of the crystal resonator should be 8 MHz to 25 MHz.																				

Item

Page

Revision (See Manual for Details)

21.2.2

External Clock Input

679

Description added in the 5th line.

Table 21.3 shows the input conditions for the external clock.

The frequency of an external clock to be input should be 8 MHz to 25 MHz.

21.4

Frequency Divider

681

Description amended in the 11th line.

The frequency divider divides the PLL output clock to generate a 1/2 or 1/4 clock.

21.5.3

Notes on Board Design

682

Description of (Values are preliminary recommended values.) deleted.

Figure 21.7 Recommended External Circuitry for PLL Circuit

Section 22

Power-Down Modes

684

Table amended.

Operating State	High Speed Mode	Clock Division Mode	Sleep Mode	Module Stop Mode	All Module Clock Stop Mode	Software Standby Mode	Hardware Standby Mode
External interrupts	NMI	Functions	Functions	Functions	Functions	Functions	Halted
Peripheral functions	A/D	Functions	Functions	Functions	Halted (Retained)	Halted (Retained)	Halted (Reset)
	SCI	Functions	Functions	Functions	Halted ^{*3} (Reset/Retained)	Halted ^{*3} (Reset/Retained)	Halted ^{*3} (Reset/Retained)
	IIC2	Functions	Functions	Functions	Halted ^{*4} (Reset/Retained)	Halted ^{*4} (Reset/Retained)	Halted ^{*4} (Reset/Retained)

Notes added.

Notes: ^{*3} TDR, SSR, and RDR are halted (reset) and other registers are halted (retained).
^{*4} BC2 to BC0 are halted (reset) and other registers are halted (retained).

22.2.1

Clock Division Mode

690

Description amended in the 5th line.

In clock division mode, the CPU, bus masters, and on-chip peripheral functions all operate on the operating clock (1/2 or 1/4) specified by bits SCK2 to SCK0.

22.4.6

Notes on Clock Division Mode

697

Newly added.

23.1

Section 1 Overview

1.1 Features

- High-speed H8S/2000 central processing unit with an internal 16-bit architecture
Upward-compatible with H8/300 and H8/300H CPUs on an object level
Sixteen 16-bit general registers
65 basic instructions
- Various peripheral functions
DMA controller (DMAC)*
Data transfer controller (DTC)
16-bit timer-pulse unit (TPU)
Programmable pulse generator (PPG)*
8-bit timer (TMR)
Watchdog timer (WDT)
Asynchronous or clocked synchronous serial communication interface (SCI)
I²C bus interface 2 (IIC2)
10-bit A/D converter
8-bit D/A converter
Clock pulse generator

Note: * Not supported by the H8S/2366.

- On-chip memory

ROM Type	Model	ROM	RAM	Remarks
Flash memory version	HD64F2367	384 kbytes	24 kbytes	
	HD64F2366	384 kbytes	30 kbytes	In planning stage
Masked ROM version	HD6432365	256 kbytes	16 kbytes	
ROMless version	HD6412363	—	16 kbytes	

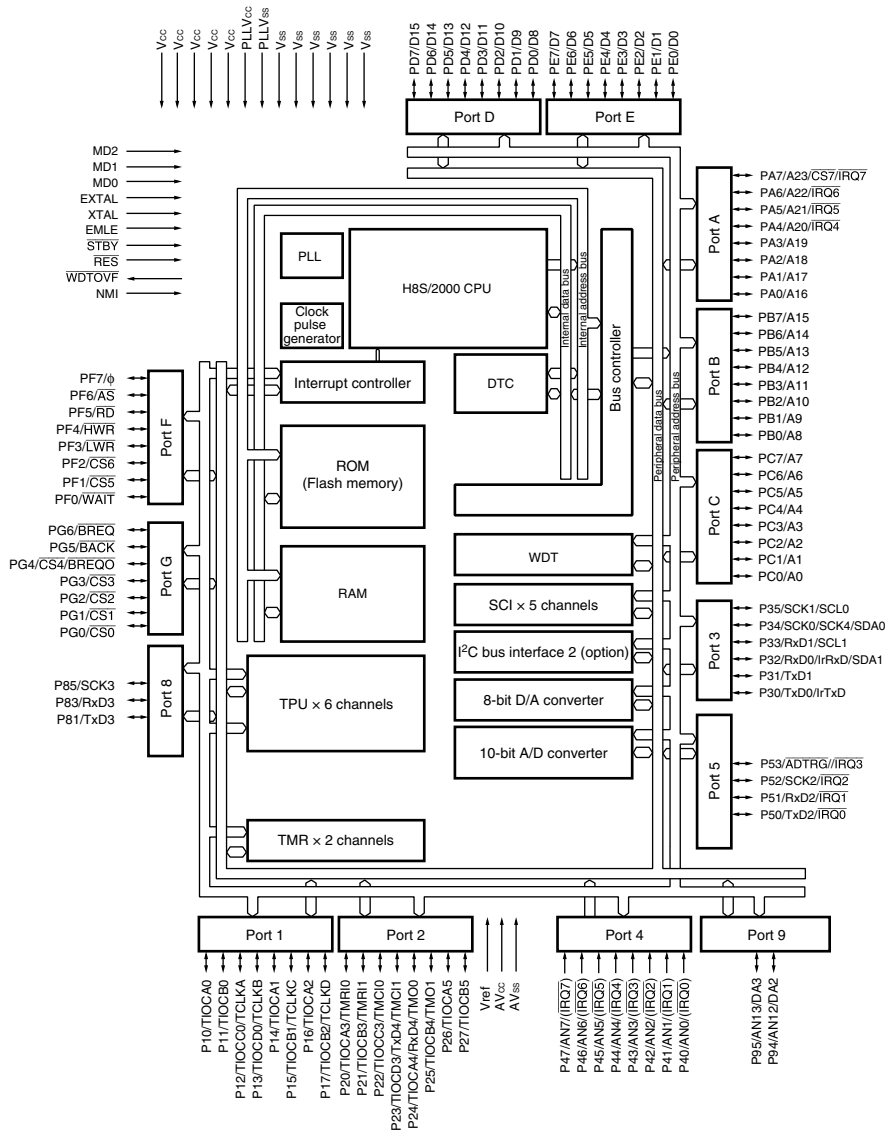

- General I/O ports
I/O pins: 84
Input-only pins: 10
- Supports various power-down states
- Compact package

Package	Code	Body Size	Pin Pitch
TFP-120	TFP-120 (TFP-120V*)	14.0 × 14.0 mm	0.4 mm
QFP-128	FP-128B (FP-128BV*)	14.0 × 20.0 mm	0.5 mm

Note: * Pb free version

Figures 1.1 and 1.2 show the internal block diagrams of this LSI.

1.3 Pin Description

1.3.1 Pin Arrangement

Figures 1.3 to 1.6 show the pin arrangements of this LSI.

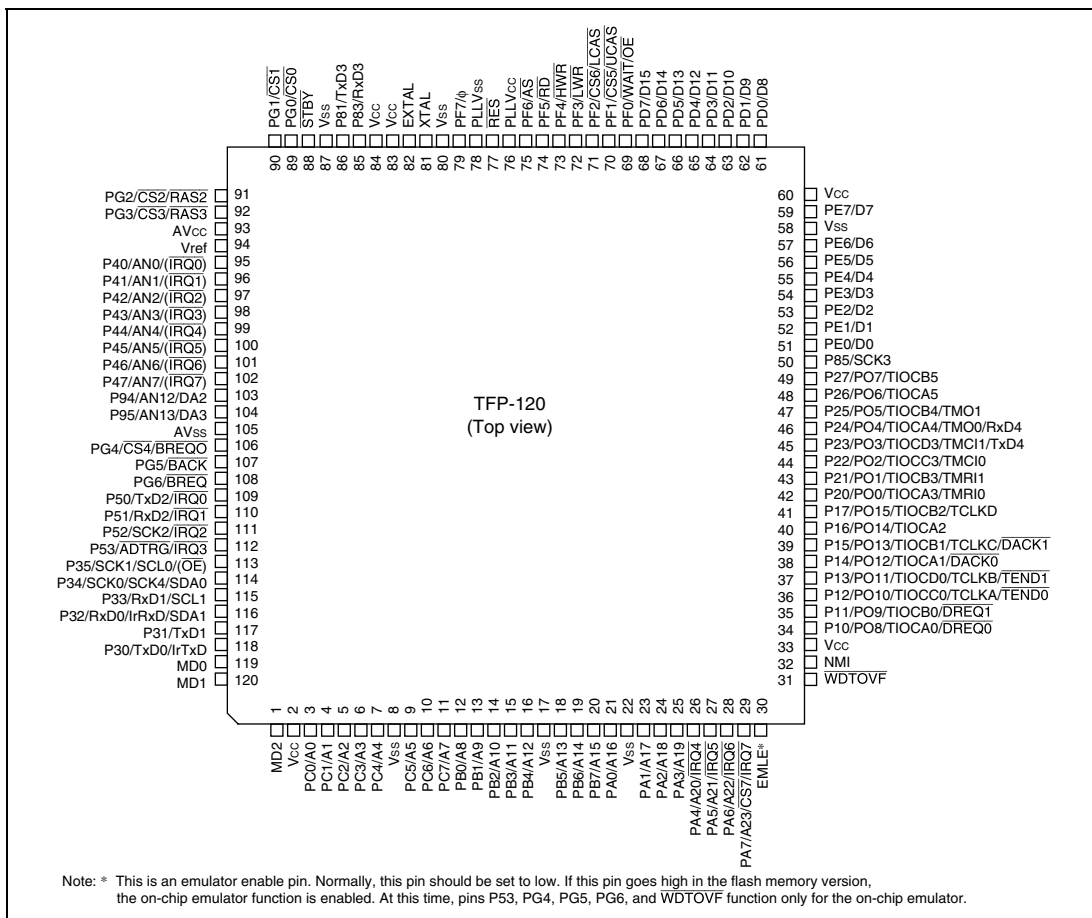

Figure 1.3 Pin Arrangement of H8S/2367, H8S/2365, and H8S/2363

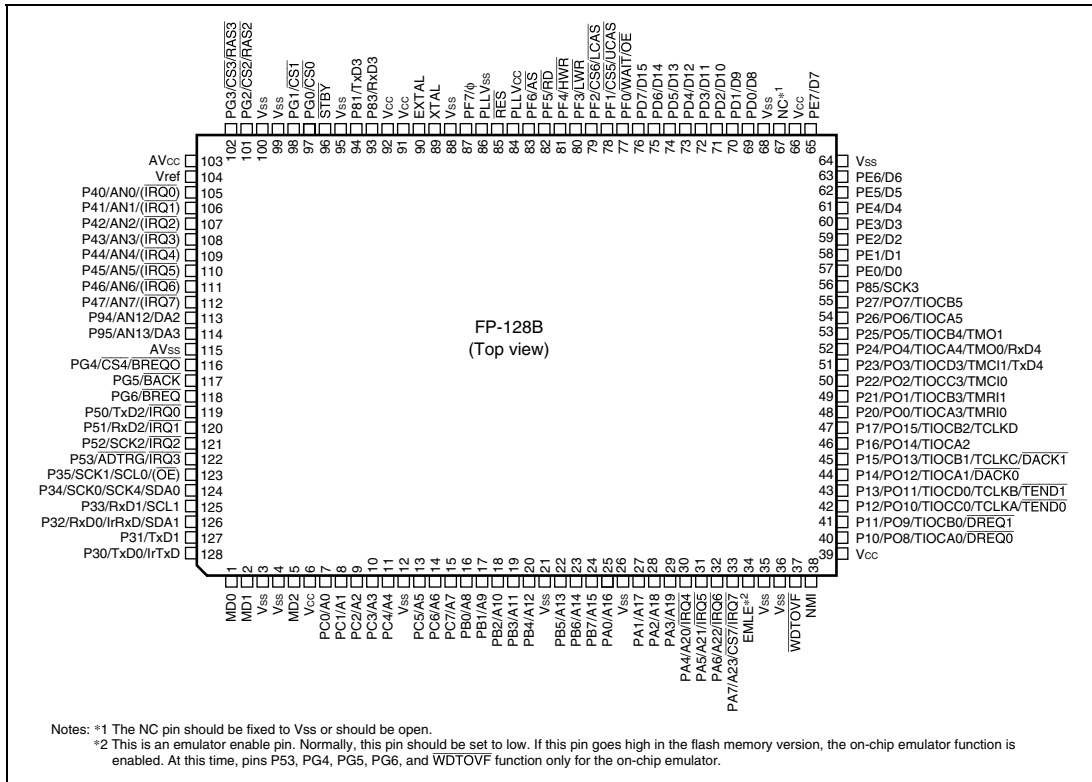

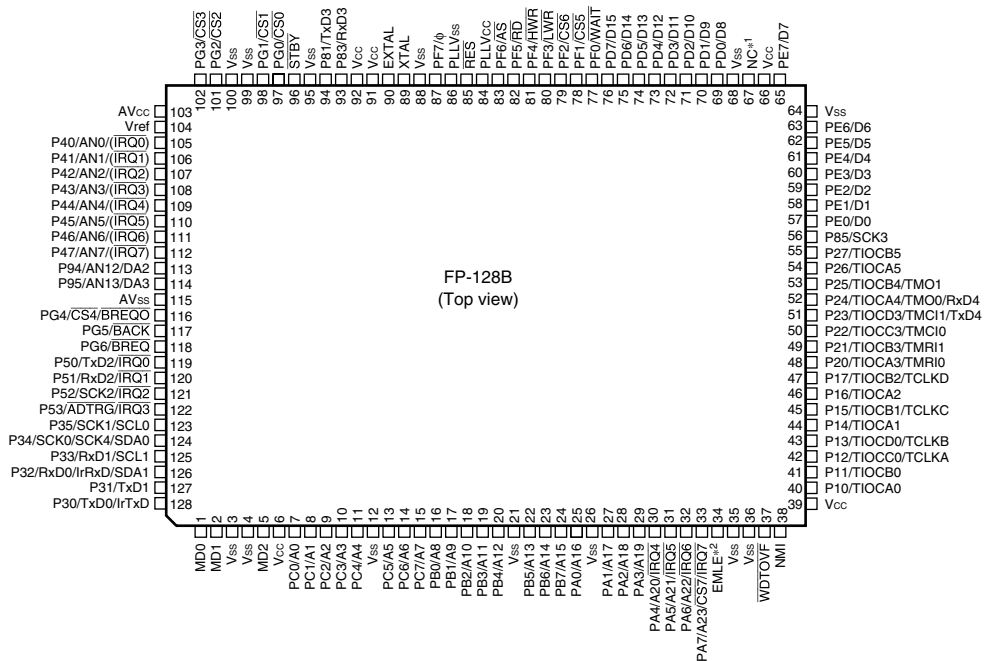

Figure 1.5 Pin Arrangement of H8S/2367, H8S/2365, and H8S/2363

Notes: *1 The NC pin should be fixed to Vss or should be open.
 *2 This pin should be set to low and should not be changed during operation.

1.3.3 Pin Functions

Table 1.2 Pin Functions

Type	Symbol	Pin No.		I/O	Function
		TFP-120	QFP-128		
Power	V_{cc}	2,33,60, 83,84	6,39,66, 91,92	Input	Power supply pins. V_{cc} pins should be connected to the system power supply.
	V_{ss}	8,17,22, 58,80,87	3,4,12, 21,26,35, 36,64,68 88,95,99 100	Input	Ground pins. V_{ss} pins should be connected to the system power supply (0 V).
	$PLL_{V_{cc}}$	76	84	Input	Power supply pin for the on-chip PLL oscillator.
	$PLL_{V_{ss}}$	78	86	Input	Ground pin for the on-chip PLL oscillator.
Clock	XTAL	81	89	Input	For connection to a crystal oscillator. See section 21, Clock Pulse Generator for typical connection diagrams for a crystal oscillator and external clock input.
	EXTAL	82	90	Input	For connection to a crystal oscillator. The EXTAL pin can also input an external clock. See section 21, Clock Pulse Generator for typical connection diagrams for a crystal oscillator and external clock input.
	0	79	87	Output	Supplies the system clock to external devices.
Operating mode control	MD2	1,	5,	Input	These pins set the operating mode. These pins should not be changed while the MCU is operating.
	MD1	120,	2,		
	MD0	119	1		
System control	\overline{RES}	77	85	Input	Reset pin. When this pin is driven low, the chip is reset.
	\overline{STBY}	88	96	Input	When this pin is driven low, a transition is made to hardware standby mode.
	EMLE	30	34	Input	Enables emulator. This pin should be connected to the power supply (0 V).

Type	Symbol	Pin No.		I/O	Function
		TFP-120	QFP-128		
Address bus	A23 to A0	29 to 23, 21 to 18, 16 to 9, 7 to 3	33 to 27, 25 to 22, 20 to 13, 11 to 7	Output	Address output pins.
Data bus	D15 to D0	68 to 61, 59, 57 to 51	76 to 69, 65, 63 to 57	Input/ output	These pins constitute a bidirectional data bus.
Bus control	$\overline{CS7}$ to $\overline{CS0}$	29,71,70, 106, 92 to 89	33,79,78, 116,102, 101,98,97	Output	Signals that select division areas 7 to 0 in the external address space.
	\overline{AS}	75	83	Output	When this pin is low, it indicates that address output on the address bus is valid.
	\overline{RD}	74	82	Output	When this pin is low, it indicates that the external address space is being read.
	\overline{HWR}	73	81	Output	Strobe signal indicating that external address space is to be written, and the upper half (D15 to D8) of the data bus is enabled. Write enable signal for accessing the DRAM space.
	\overline{LWR}	72	80	Output	Strobe signal indicating that external address space is to be written, and the lower half (D7 to D0) of the data bus is enabled.
	\overline{BREQ}	108	118	Input	The external bus master requests the bus to this LSI.
	\overline{BREQO}	106	116	Input	External bus request signal when the internal bus master accesses the external space in external bus release state.
	\overline{BACK}	107	117	Output	Indicates the bus is released to the external bus master.
	\overline{UCAS}^*	70	78	Output	Upper column address strobe signal for accessing the 16-bit DRAM space. Column address strobe signal for accessing the 8-bit DRAM space.

Type	Symbol	Pin No.		I/O	Function
		TFP-120	QFP-128		
Bus control	$\overline{\text{LCAS}}^*$	71	79	Output	Lower column address strobe signal for accessing the 16-bit DRAM space.
	$\overline{\text{RAS2}}^*$	91	101	Output	Row address strobe signal for the DRAM interface.
	$\overline{\text{RAS3}}^*$	92	102		
	$\overline{\text{WAIT}}^*$	69	77	Input	Requests insertion of a wait state in the bus cycle when accessing external 3-state address space.
	$\overline{\text{OE}}^*$ $(\overline{\text{OE}})^*$	69, 113	77, 123	Output	Output enable signal for accessing the DRAM space. The output pins of $\overline{\text{OE}}$ and $(\overline{\text{OE}})$ are selected by the port function control register 2 (PFCR2) of port 3.
Interrupt signals	NMI	32	38	Input	Nonmaskable interrupt request pin. Fix high when not used.
	$\overline{\text{IRQ7}}$ to $\overline{\text{IRQ0}}$ $(\overline{\text{IRQ7}})$ to $(\overline{\text{IRQ0}})$	29 to 26, 112 to 109, 102 to 95	33 to 30, 122 to 119, 112 to 105	Input	These pins request a maskable interrupt. The input pins of $\overline{\text{IRQn}}$ and $(\overline{\text{IRQn}})$ are selected by the IRQ pin select register (ITSR) of the interrupt controller. (n = 0 to 7)
DMA controller (DMAC)*	$\overline{\text{DREQ1}}^*$	35,	41,	Input	These signals request DMAC activation.
	$\overline{\text{DREQ0}}^*$	34	40		
	$\overline{\text{TEND1}}^*$, $\overline{\text{TEND0}}^*$	37, 36	43, 42	Output	These signals indicate the end of DMAC data transfer.
	$\overline{\text{DACK1}}^*$, $\overline{\text{DACK0}}^*$	39, 38	45, 44	Output	DMAC single address transfer acknowledge signals.
16-bit timer pulse unit (TPU)	TCLKD	41,	47,	Input	External clock input pins for the timer.
	TCLKC	39,	45,		
	TCLKB	37,	43,		
	TCLKA	36	42		
	TIOCA0	34,	40,	Input/ output	TGRA_0 to TGRD_0 input capture input/output compare output/PWM output pins.
	TIOCB0	35,	41,		
	TIOCC0	36,	42,		
	TIOCD0	37	43		
	TIOCA1	38,	44,	Input/ output	TGRA_1 and TGRB_1 input capture input/output compare output/PWM output pins.
	TIOCB1	39	45		

Type	Symbol	Pin No.		I/O	Function
		TFP-120	QFP-128		
16-bit timer pulse unit (TPU)	TIOCA2	40,	46,	Input/output	TGRA_2 and TGRB_2 input capture input/output compare output/PWM output pins.
	TIOCB2	41	47		
	TIOCA3	42,	48,	Input/output	TGRA_3 to TGRD_3 input capture input/output compare output/PWM output pins.
	TIOCB3	43,	49,		
	TIOCC3	44,	50,		
	TIOCD3	45	51		
16-bit timer pulse unit (TPU)	TIOCA4	46,	52,	Input/output	TGRA_4 and TGRB_4 input capture input/output compare output/PWM output pins.
	TIOCB4	47	53		
	TIOCA5	48,	54,	Input/output	TGRA_5 and TGRB_5 input capture input/output compare output/PWM output pins.
	TIOCB5	49	55		
Programmable pulse generator (PPG)*	PO15 to PO0*	41 to 34, 49 to 42	47 to 40, 55 to 48	Output	Pulse output pins.
8-bit timer (TMR)	TMO0	46,	52,	Output	Waveform output pins with output compare function.
	TMO1	47	53		
	TMCI0	44,	50,	Input	External event input pins.
	TMCI1	45	51		
	TMRI0	42,	48,	Input	Counter reset input pins.
	TMRI1	43	49		
Watchdog Timer(WDT)	WDTOVF	31	37	Output	Counter overflow signal output pin in watchdog timer mode.
Serial communication interface(SCI)/ smart card interface (SCI_0 with IrDA function)	TxD4	45,	51,	Output	Data output pins.
	TxD3	86,	94,		
	TxD2	109,	119,		
	TxD1	117,	127,		
	TxD0/ IrTxD	118	128		
	RxD4	46,	52,	Input	Data input pins.
	RxD3	85,	93,		
	RxD2	110,	120		
	RxD1	115,	125,		
	RxD0/ IrRxD	116	126		
	SCK4	114,	124,	Input/output	Clock input/output pins.
	SCK3	50,	56,		
	SCK2	111,	121,		
	SCK1	113,	123,		
	SCK0	114	124		

Type	Symbol	Pin No.		I/O	Function
		TFP-120	QFP-128		
IIC bus interface2 (IIC2)	SCL1 SCL0	115, 113	125, 123	Input/ output	IIC clock input/output pins.
IIC bus interface (IIC)	SDA1 SDA0	116, 114	126, 124	Input/ output	IIC data input/output pins.
A/D converter	AN13, AN12, AN7 to AN0	104 to 95	114 to 105	Input	Analog input pins.
	ADTRG	112	122	Input	Pin for input of an external trigger to start A/D conversion.
D/A converter	DA3, DA2	104, 103	114, 113	Output	Analog output pins.
A/D converter, D/A converter	AV _{cc}	93	103	Input	The analog power-supply pin for the A/D converter and D/A converter. When the A/D converter and D/A converter are not used, this pin should be connected to the system power supply (+3 V).
	AV _{ss}	105	115	Input	The ground pin for the A/D converter and D/A converter. This pin should be connected to the system power supply (0 V).
	Vref	94	104	Input	The reference voltage input pin for the A/D converter and D/A converter. When the A/D converter and D/A converter are not used, this pin should be connected to the system power supply (+3 V).
I/O ports	P17 to P10	41 to 34	47 to 40	Input/ output	Eight-bit input/output pins.
	P27 to P20	49 to 42	55 to 48	Input/ output	Eight-bit input/output pins.
	P35 to P30	113 to 118	123 to 128	Input/ output	Six-bit input/output pins.
	P47 to P40	102 to 95	112 to 105	Input	Eight-bit input pins.
	P53 to P50	112 to 109	122 to 119	Input/ output	Four-bit input/output pins.

Type	Symbol	Pin No.		I/O	Function
		TFP-120	QFP-128		
I/O ports	P85, P83, P81	50, 85, 86	56, 93, 94	Input/ output	Three-bit input/output pins.
	P95, P94	104, 103	114, 113	Input	Two-bit input pins.
	PA7 to PA0	29 to 23, 21	33 to 27, 25	Input/ output	Eight-bit input/output pins.
	PB7 to PB0	20 to 18, 16 to 12	24 to 22, 20 to 16	Input/ output	Eight-bit input/output pins.
	PC7 to PC0	11 to 9, 7 to 3	15 to 13, 11 to 7	Input/ output	Eight-bit input/output pins.
	PD7 to PD0	68 to 61	76 to 69	Input/ output	Eight-bit input/output pins.
	PE7 to PE0	59, 57 to 51	65, 63 to 57	Input/ output	Eight-bit input/output pins.
	PF7 to PF0	79, 75 to 69	87, 83 to 77	Input/ output	Eight-bit input/output pins.
	PG6 to PG0	108 to 106, 92 to 89	118 to 116, 102,101, 98,97	Input/ output	Seven-bit input/output pins.

Note: * Not supported by the H8S/2366.

Section 2 CPU

The H8S/2000 CPU is a high-speed central processing unit with an internal 32-bit architecture that is upward-compatible with the H8/300 and H8/300H CPUs. The H8S/2000 CPU has sixteen 16-bit general registers, can address a 16-Mbyte linear address space, and is ideal for realtime control.

This section describes the H8S/2000 CPU. The usable modes and address spaces differ depending on the product. For details on each product, refer to section 3, MCU Operating Modes.

2.1 Features

- Upward-compatibility with H8/300 and H8/300H CPUs
 - Can execute H8/300 and H8/300H CPU object programs
- General-register architecture
 - Sixteen 16-bit general registers also usable as sixteen 8-bit registers or eight 32-bit registers
- Sixty-five basic instructions
 - 8/16/32-bit arithmetic and logic instructions
 - Multiply and divide instructions
 - Powerful bit-manipulation instructions
- Eight addressing modes
 - Register direct [Rn]
 - Register indirect [@ERn]
 - Register indirect with displacement [@(d:16,ERn) or @(d:32,ERn)]
 - Register indirect with post-increment or pre-decrement [@ERn+ or @-ERn]
 - Absolute address [@aa:8, @aa:16, @aa:24, or @aa:32]
 - Immediate [#xx:8, #xx:16, or #xx:32]
 - Program-counter relative [@(d:8,PC) or @(d:16,PC)]
 - Memory indirect [@@aa:8]
- 16-Mbyte address space
 - Program: 16 Mbytes
 - Data: 16 Mbytes
- High-speed operation
 - All frequently-used instructions are executed in one or two states
 - 8/16/32-bit register-register add/subtract: 1 state
 - 8×8 -bit register-register multiply: 12 states (MULXU.B), 13 states (MULXS.B)
 - $16 \div 8$ -bit register-register divide: 12 states (DIVXU.B)
 - 16×16 -bit register-register multiply: 20 states (MULXU.W), 21 states (MULXS.W)
 - $32 \div 16$ -bit register-register divide: 20 states (DIVXU.W)

- Two CPU operating modes
 - Normal mode*
 - Advanced mode

Note: * For this LSI, normal mode is not available.

- Power-down state
 - Transition to power-down state by SLEEP instruction
 - Selectable CPU clock speed

2.1.1 Differences between H8S/2600 CPU and H8S/2000 CPU

The differences between the H8S/2600 CPU and the H8S/2000 CPU are as shown below.

- Register configuration

The MAC register is supported only by the H8S/2600 CPU.
- Basic instructions

The four instructions MAC, CLRMAC, LDMAC, and STMAC are supported only by the H8S/2600 CPU.
- The number of execution states of the MULXU and MULXS instructions

Instruction	Mnemonic	Execution States	
		H8S/2600	H8S/2000
MULXU	MULXU.B Rs, Rd	3	12
	MULXU.W Rs, ERd	4	20
MULXS	MULXS.B Rs, Rd	4	13
	MULXS.W Rs, ERd	5	21

In addition, there are differences in address space, CCR and EXR register functions, power-down modes, etc., depending on the model.

2.1.2 Differences from H8/300 CPU

In comparison to the H8/300 CPU, the H8S/2000 CPU has the following enhancements.

- More general registers and control registers
 - Eight 16-bit extended registers, and one 8-bit and two 32-bit control registers, have been added.
- Expanded address space
 - Normal mode supports the same 64-kbyte address space as the H8/300 CPU.
 - Advanced mode supports a maximum 16-Mbyte address space.
- Enhanced addressing
 - The addressing modes have been enhanced to make effective use of the 16-Mbyte address space.
- Enhanced instructions
 - Addressing modes of bit-manipulation instructions have been enhanced.
 - Signed multiply and divide instructions have been added.
 - Two-bit shift and two-bit rotate instructions have been added.
 - Instructions for saving and restoring multiple registers have been added.
 - A test and set instruction has been added.
- Higher speed
 - Basic instructions are executed twice as fast.

2.1.3 Differences from H8/300H CPU

In comparison to the H8/300H CPU, the H8S/2000 CPU has the following enhancements.

- Additional control register
 - One 8-bit control register has been added.
- Enhanced instructions
 - Addressing modes of bit-manipulation instructions have been enhanced.
 - Two-bit shift and two-bit rotate instructions have been added.
 - Instructions for saving and restoring multiple registers have been added.
 - A test and set instruction has been added.
- Higher speed
 - Basic instructions are executed twice as fast.

2.2 CPU Operating Modes

The H8S/2000 CPU has two operating modes: normal and advanced. Normal mode supports a maximum 64-kbyte address space. Advanced mode supports a maximum 16-Mbyte address space. The mode is selected by the LSI's mode pins.

2.2.1 Normal Mode

The exception vector table and stack have the same structure as in the H8/300 CPU in normal mode.

- Address space
Linear access to a maximum address space of 64 kbytes is possible.
- Extended registers (En)
The extended registers (E0 to E7) can be used as 16-bit registers, or as the upper 16-bit segments of 32-bit registers.
When extended register En is used as a 16-bit register it can contain any value, even when the corresponding general register (Rn) is used as an address register. (If general register Rn is referenced in the register indirect addressing mode with pre-decrement (@-Rn) or post-increment (@Rn+) and a carry or borrow occurs, the value in the corresponding extended register (En) will be affected.)
- Instruction set
All instructions and addressing modes can be used. Only the lower 16 bits of effective addresses (EA) are valid.
- Exception vector table and memory indirect branch addresses
In normal mode, the top area starting at H'0000 is allocated to the exception vector table. One branch address is stored per 16 bits. The exception vector table in normal mode is shown in figure 2.1. For details of the exception vector table, see section 4, Exception Handling.
The memory indirect addressing mode (@aa:8) employed in the JMP and JSR instructions uses an 8-bit absolute address included in the instruction code to specify a memory operand that contains a branch address. In normal mode, the operand is a 16-bit (word) operand, providing a 16-bit branch address. Branch addresses can be stored in the top area from H'0000 to H'00FF. Note that this area is also used for the exception vector table.
- Stack structure
When the program counter (PC) is pushed onto the stack in a subroutine call, and the PC, condition-code register (CCR), and extended control register (EXR) are pushed onto the stack in exception handling, they are stored as shown in figure 2.2. EXR is not pushed onto the stack in interrupt control mode 0. For details, see section 4, Exception Handling.

Note: For this LSI, normal mode is not available.

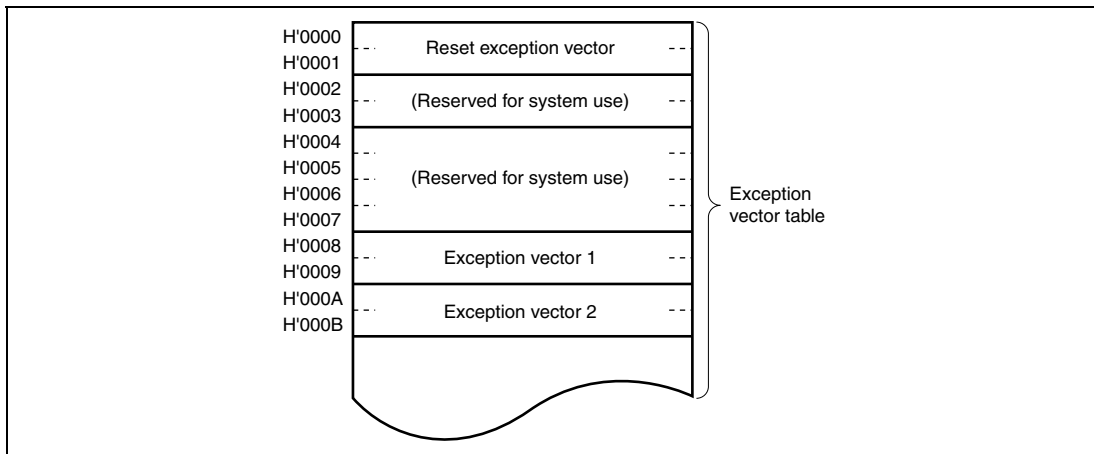

Figure 2.1 Exception Vector Table (Normal Mode)

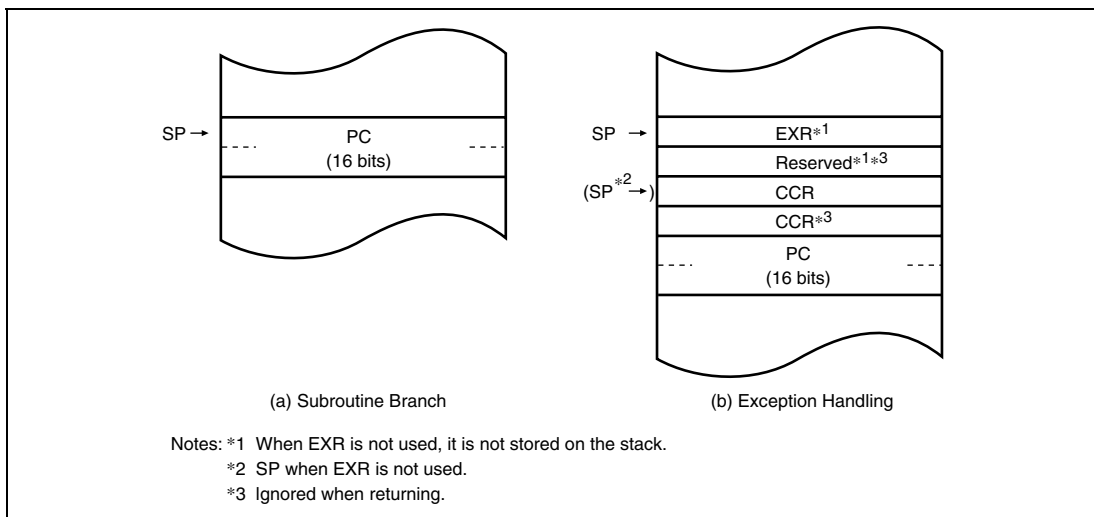

Figure 2.2 Stack Structure in Normal Mode

2.2.2 Advanced Mode

- Address space

Linear access to a maximum address space of 16 Mbytes is possible.

- Extended registers (En)

The extended registers (E0 to E7) can be used as 16-bit registers. They can also be used as the upper 16-bit segments of 32-bit registers or address registers.

- Instruction set

All instructions and addressing modes can be used.

- Exception vector table and memory indirect branch addresses

In advanced mode, the top area starting at H'00000000 is allocated to the exception vector table in 32-bit units. In each 32 bits, the upper 8 bits are ignored and a branch address is stored in the lower 24 bits (see figure 2.3). For details of the exception vector table, see section 4, Exception Handling.

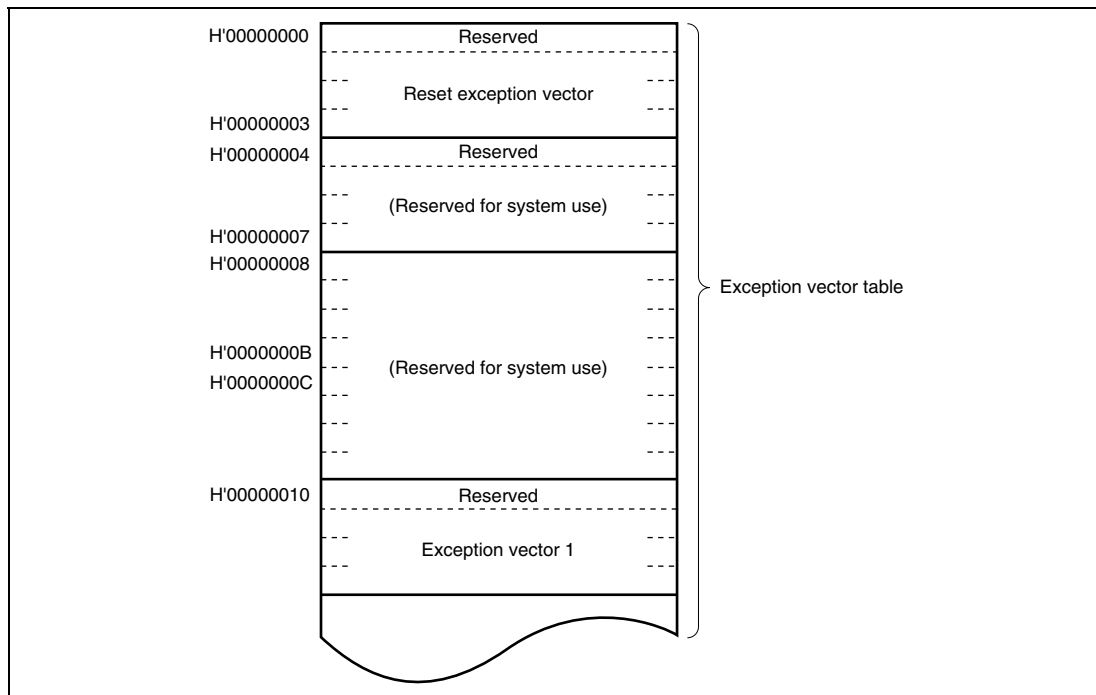

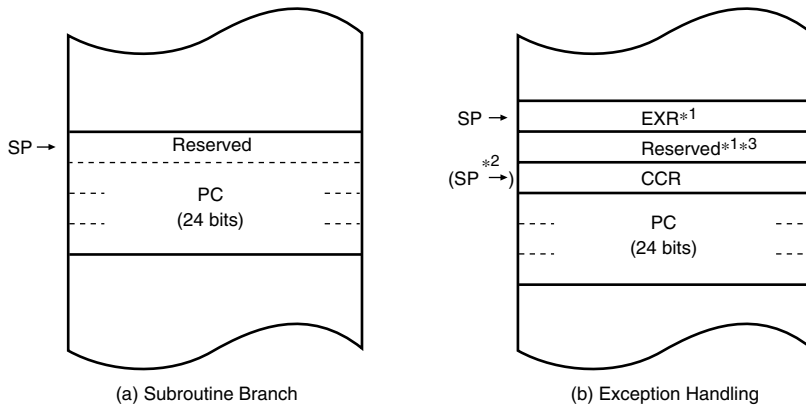

Figure 2.3 Exception Vector Table (Advanced Mode)

The memory indirect addressing mode (@@aa:8) employed in the JMP and JSR instructions uses an 8-bit absolute address included in the instruction code to specify a memory operand that contains a branch address. In advanced mode, the operand is a 32-bit longword operand, providing a 32-bit branch address. The upper 8 bits of these 32 bits are a reserved area that is regarded as H'00. Branch addresses can be stored in the area from H'00000000 to H'000000FF. Note that the top area of this range is also used for the exception vector table.

- Stack structure

In advanced mode, when the program counter (PC) is pushed onto the stack in a subroutine call, and the PC, condition-code register (CCR), and extended control register (EXR) are pushed onto the stack in exception handling, they are stored as shown in figure 2.4. EXR is not pushed onto the stack in interrupt control mode 0. For details, see section 4, Exception Handling.

Notes: *1 When EXR is not used, it is not stored on the stack.

*2 SP when EXR is not used.

*3 Ignored when returning.

Figure 2.4 Stack Structure in Advanced Mode

2.3 Address Space

Figure 2.5 shows a memory map of the H8S/2000 CPU. The H8S/2000 CPU provides linear access to a maximum 64-kbyte address space in normal mode, and a maximum 16-Mbyte (architecturally 4-Gbyte) address space in advanced mode. The usable modes and address spaces differ depending on the product. For details on each product, refer to section 3, MCU Operating Modes.

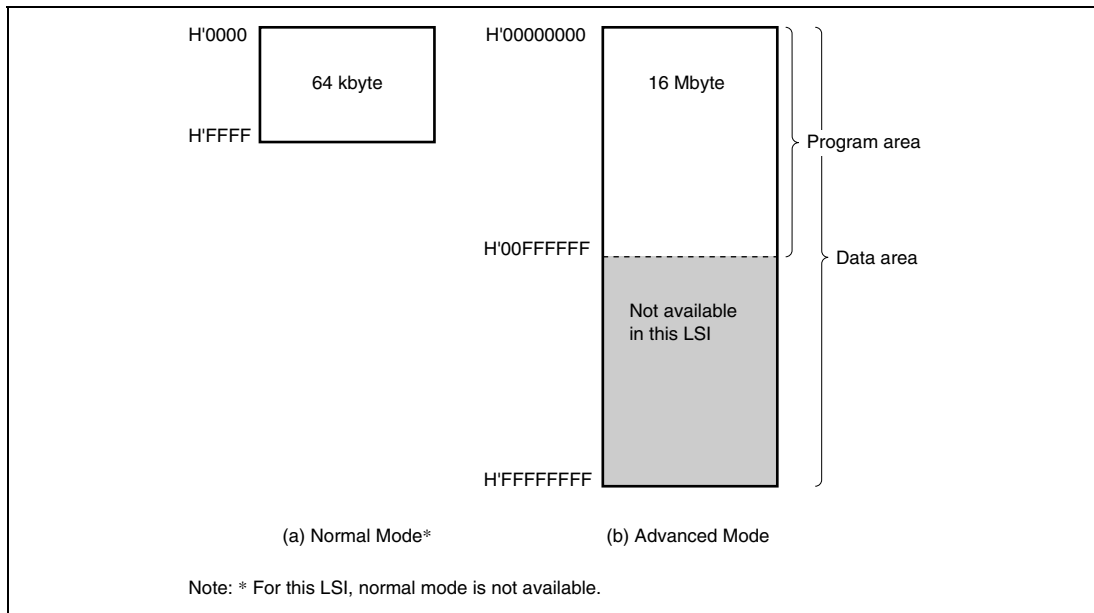

Figure 2.5 Memory Map

2.4 Register Configuration

The H8S/2000 CPU has the internal registers shown in figure 2.6. There are two types of registers: general registers and control registers. Control registers are a 24-bit program counter (PC), an 8-bit extended control register (EXR), and an 8-bit condition code register (CCR).

General Registers (Rn) and Extended Registers (En)

	15	0 7	0 7	0
ER0	E0	R0H	R0L	
ER1	E1	R1H	R1L	
ER2	E2	R2H	R2L	
ER3	E3	R3H	R3L	
ER4	E4	R4H	R4L	
ER5	E5	R5H	R5L	
ER6	E6	R6H	R6L	
ER7 (SP)	E7	R7H	R7L	

Control Registers

Legend

SP	:Stack pointer	H	:Half-carry flag
PC	:Program counter	U	:User bit
EXR	:Extended control register	N	:Negative flag
T	:Trace bit	Z	:Zero flag
I2 to I0	:Interrupt mask bits	V	:Overflow flag
CCR	:Condition-code register	C	:Carry flag
I	:Interrupt mask bit		
UI	:User bit or interrupt mask bit*		

Note: * For this LSI, the interrupt mask bit is not available.

Figure 2.6 CPU Internal Registers

2.4.1 General Registers

The H8S/2000 CPU has eight 32-bit general registers. These general registers are all functionally alike and can be used as both address registers and data registers. When a general register is used as a data register, it can be accessed as a 32-bit, 16-bit, or 8-bit register. Figure 2.7 illustrates the usage of the general registers. When the general registers are used as 32-bit registers or address registers, they are designated by the letters ER (ER0 to ER7).

When the general registers are used as 16-bit registers, the ER registers are divided into 16-bit general registers designated by the letters E (E0 to E7) and R (R0 to R7). These registers are functionally equivalent, providing a maximum sixteen 16-bit registers. The E registers (E0 to E7) are also referred to as extended registers.

When the general registers are used as 8-bit registers, the R registers are divided into 8-bit general registers designated by the letters RH (R0H to R7H) and RL (R0L to R7L). These registers are functionally equivalent, providing a maximum sixteen 8-bit registers.

The usage of each register can be selected independently.

General register ER7 has the function of the stack pointer (SP) in addition to its general-register function, and is used implicitly in exception handling and subroutine calls. Figure 2.8 shows the stack.

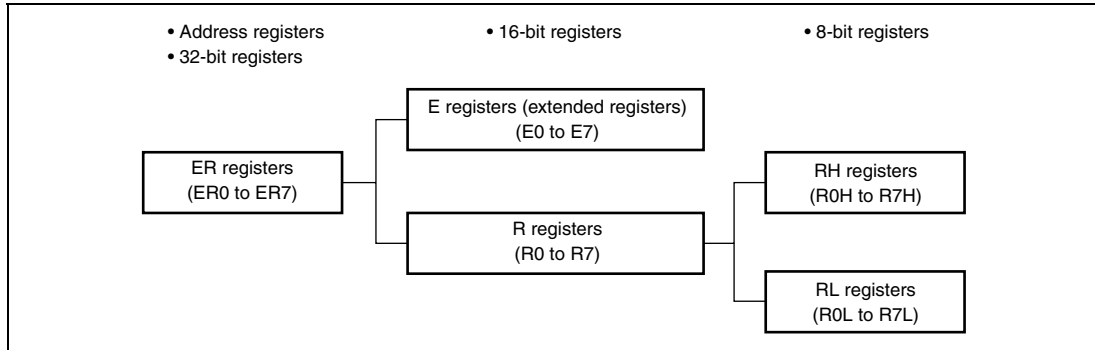

Figure 2.7 Usage of General Registers

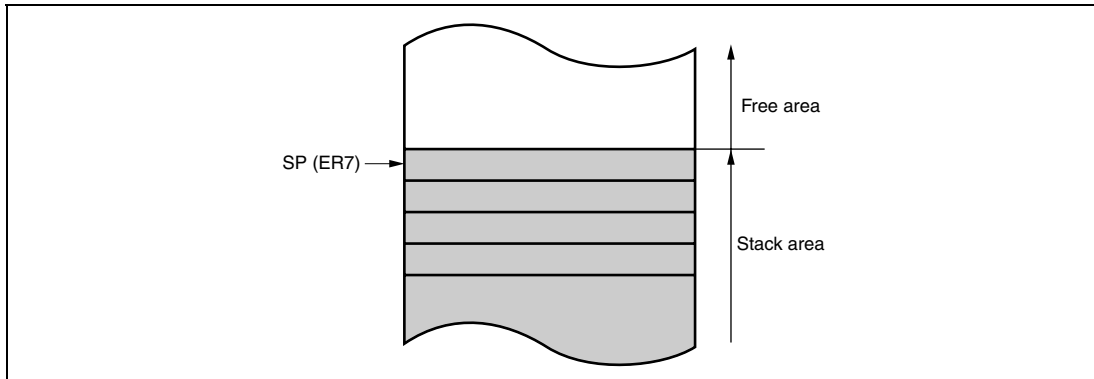

Figure 2.8 Stack

2.4.2 Program Counter (PC)

This 24-bit counter indicates the address of the next instruction the CPU will execute. The length of all CPU instructions is 2 bytes (one word), so the least significant PC bit is ignored. (When an instruction is fetched for read, the least significant PC bit is regarded as 0.)

2.4.3 Extended Control Register (EXR)

EXR is an 8-bit register that can be operated by the LDC, STC, ANDC, ORC, and XORC instructions. When an instruction other than STC is executed, all interrupts including NMI are masked in three states after the instruction is completed.

Bit	Bit Name	Initial Value	R/W	Description
7	T	0	R/W	Trace Bit When this bit is set to 1, trace exception processing starts every when an instruction is executed. When this bit is cleared to 0, instructions are consecutively executed.
6 to 3	—	1	—	Reserved These bits are always read as 1.
2 to 0	I2 I1 I0	1	R/W	Interrupt Mask Bits 2 to 0 Specify interrupt request mask levels (0 to 7). For details, see section 5, Interrupt Controller.

2.4.4 Condition-Code Register (CCR)

This 8-bit register contains internal CPU status information, including an interrupt mask bit (I) and half-carry (H), negative (N), zero (Z), overflow (V), and carry (C) flags.

Operations can be performed on the CCR bits by the LDC, STC, ANDC, ORC, and XORC instructions. The N, Z, V, and C flags are used as branching conditions for conditional branch (Bcc) instructions.

Bit	Bit Name	Initial Value	R/W	Description
7	I	1	R/W	<p>Interrupt Mask Bit</p> <p>Masks interrupts other than NMI when set to 1. NMI is accepted regardless of the I bit setting. The I bit is set to 1 at the start of an exception-handling sequence. For details, refer to section 5, Interrupt Controller.</p>
6	UI	Undefined	R/W	<p>User Bit or Interrupt Mask Bit</p> <p>Can be written to and read from by software using the LDC, STC, ANDC, ORC, and XORC instructions. For this LSI, Interrupt Mask Bit is not available.</p>
5	H	Undefined	R/W	<p>Half-Carry Flag</p> <p>When the ADD.B, ADDX.B, SUB.B, SUBX.B, CMP.B, or NEG.B instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 3, and cleared to 0 otherwise. When the ADD.W, SUB.W, CMP.W, or NEG.W instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 11, and cleared to 0 otherwise. When the ADD.L, SUB.L, CMP.L, or NEG.L instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 27, and cleared to 0 otherwise.</p>
4	U	Undefined	R/W	<p>User Bit</p> <p>Can be written to and read from by software using the LDC, STC, ANDC, ORC, and XORC instructions.</p>
3	N	Undefined	R/W	<p>Negative Flag</p> <p>Stores the value of the most significant bit of data as a sign bit.</p>
2	Z	Undefined	R/W	<p>Zero Flag</p> <p>Set to 1 to indicate zero data, and cleared to 0 to indicate non-zero data.</p>
1	V	Undefined	R/W	<p>Overflow Flag</p> <p>Set to 1 when an arithmetic overflow occurs, and cleared to 0 otherwise.</p>
0	C	Undefined	R/W	<p>Carry Flag</p> <p>Set to 1 when a carry occurs, and cleared to 0 otherwise. Used by:</p> <ul style="list-style-type: none"> • Add instructions, to indicate a carry • Subtract instructions, to indicate a borrow • Shift and rotate instructions, to indicate a carry <p>The carry flag is also used as a bit accumulator by bit manipulation instructions.</p>

2.4.5 Initial Register Values

Reset exception handling loads the CPU's program counter (PC) from the vector table, clears the trace (T) bit in EXR to 0, and sets the interrupt mask (I) bits in CCR and EXR to 1. The other CCR bits and the general registers are not initialized. Note that the stack pointer (ER7) is undefined. The stack pointer should therefore be initialized by an MOV.L instruction executed immediately after a reset.

2.5 Data Formats

The H8S/2000 CPU can process 1-bit, 4-bit BCD, 8-bit (byte), 16-bit (word), and 32-bit (longword) data. Bit-manipulation instructions operate on 1-bit data by accessing bit n (n = 0, 1, 2, ..., 7) of byte operand data. The DAA and DAS decimal-adjust instructions treat byte data as two digits of 4-bit BCD data.

2.5.1 General Register Data Formats

Figure 2.9 shows the data formats of general registers.

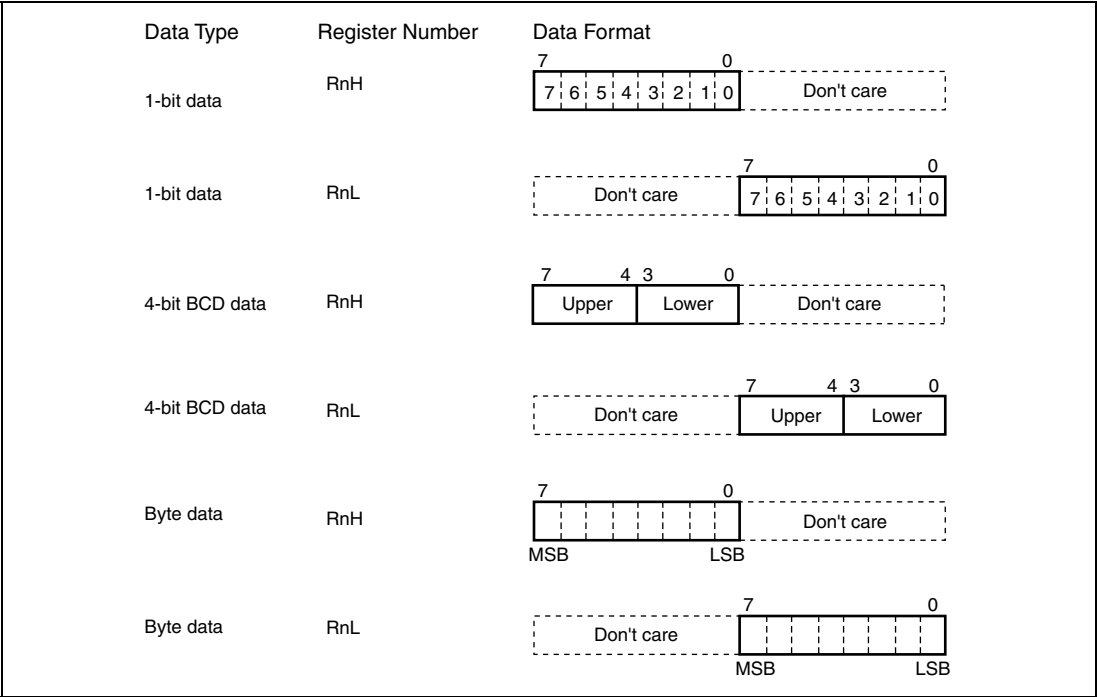

Figure 2.9 General Register Data Formats (1)

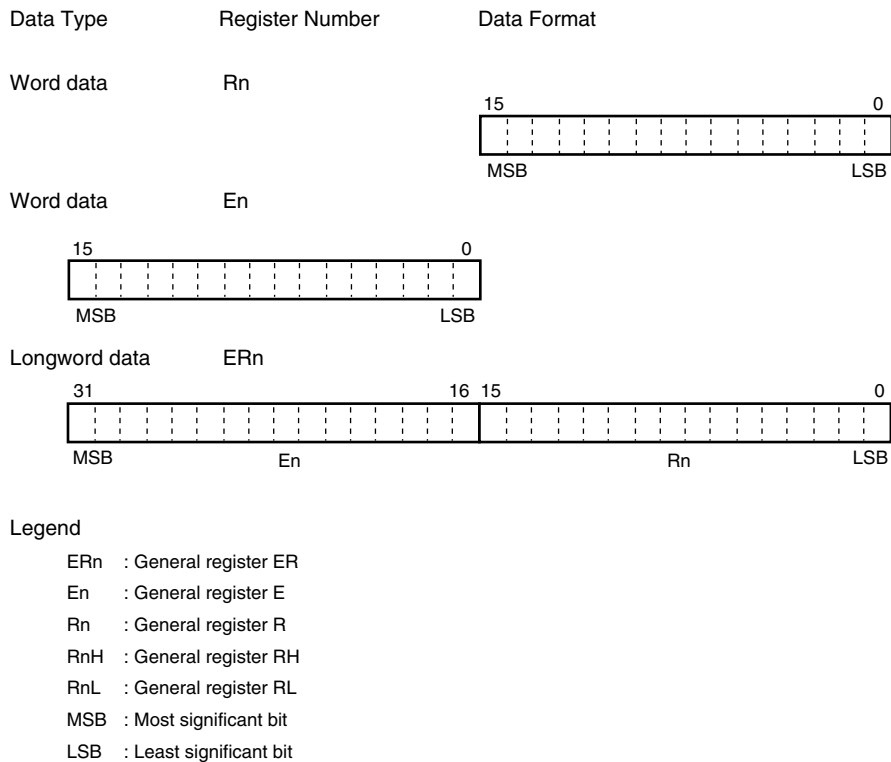

Figure 2.9 General Register Data Formats (2)

2.5.2 Memory Data Formats

Figure 2.10 shows the data formats in memory. The H8S/2000 CPU can access word data and longword data in memory, but word or longword data must begin at an even address. If an attempt is made to access word or longword data at an odd address, no address error occurs but the least significant bit of the address is regarded as 0, so the access starts at the preceding address. This also applies to instruction fetches.

When SP (ER7) is used as an address register to access the stack, the operand size should be word size or longword size.

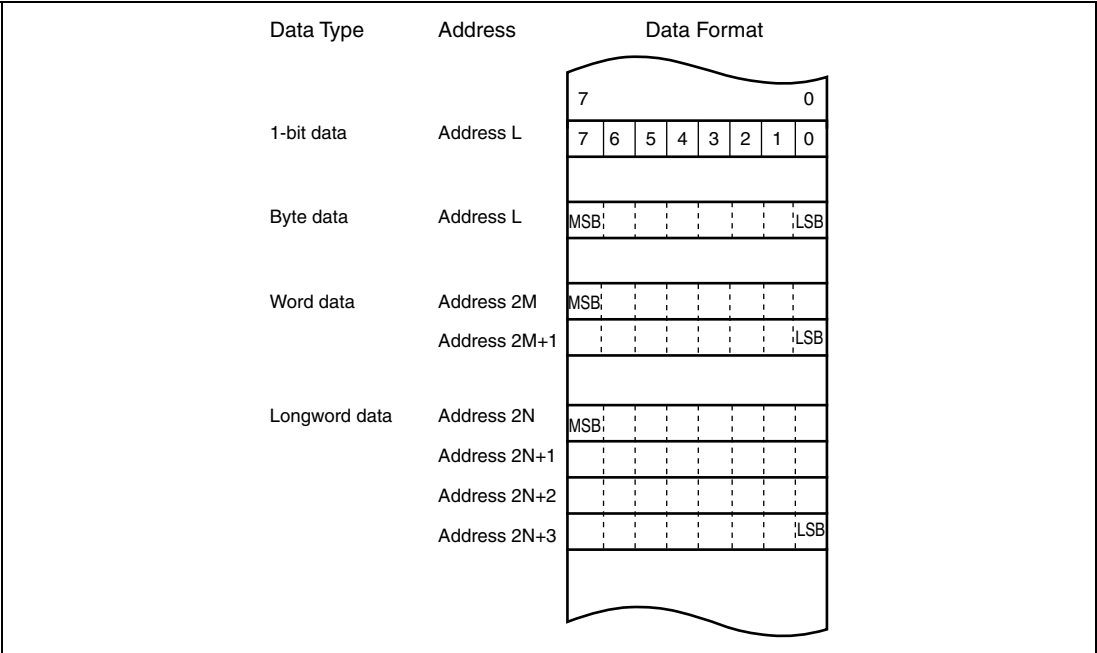

Figure 2.10 Memory Data Formats

2.6 Instruction Set

The H8S/2000 CPU has 65 types of instructions. The instructions are classified by function as shown in table 2.1.

Table 2.1 Instruction Classification

Function	Instructions	Size	Types
Data transfer	MOV	B/W/L	5
	POP* ¹ , PUSH* ¹	W/L	
	LDM, STM	L	
	MOVFP* ³ , MOVTPE* ³	B	
Arithmetic operations	ADD, SUB, CMP, NEG	B/W/L	19
	ADDX, SUBX, DAA, DAS	B	
	INC, DEC	B/W/L	
	ADDS, SUBS	L	
	MULXU, DIVXU, MULXS, DIVXS	B/W	
	EXTU, EXTS	W/L	
	TAS* ⁴	B	
Logic operations	AND, OR, XOR, NOT	B/W/L	4
Shift	SHAL, SHAR, SHLL, SHLR, ROTL, ROTR, ROTXL, ROTXR	B/W/L	8
Bit manipulation	BSET, BCLR, BNOT, BTST, BLD, BILD, BST, BIST, BAND, BBIAND, BOR, BIOR, BXOR, BIXOR	B	14
Branch	B _{cc} * ² , JMP, BSR, JSR, RTS	—	5
System control	TRAPA, RTE, SLEEP, LDC, STC, ANDC, ORC, XORC, NOP	—	9
Block data transfer	EEPMOV	—	1

Total: 65

Notes: B: Byte size; W: Word size; L: Longword size.

*1 POP.W Rn and PUSH.W Rn are identical to MOV.W @SP+, Rn and MOV.W Rn, @-SP. POP.L ERn and PUSH.L ERn are identical to MOV.L @SP+, ERn and MOV.L ERn, @-SP.

*2 BCC is the general name for conditional branch instructions.

*3 Cannot be used in this LSI.

*4 Only register ER0, ER1, ER4, or ER5 should be used when using the TAS instruction.

2.6.1 Table of Instructions Classified by Function

Tables 2.3 to 2.10 summarize the instructions in each functional category. The notation used in tables 2.3 to 2.10 is defined below.

Table 2.2 Operation Notation

Symbol	Description
Rd	General register (destination)*
Rs	General register (source)*
Rn	General register*
ERn	General register (32-bit register)
(EAd)	Destination operand
(EAs)	Source operand
EXR	Extended control register
CCR	Condition-code register
N	N (negative) flag in CCR
Z	Z (zero) flag in CCR
V	V (overflow) flag in CCR
C	C (carry) flag in CCR
PC	Program counter
SP	Stack pointer
#IMM	Immediate data
disp	Displacement
+	Addition
−	Subtraction
×	Multiplication
÷	Division
^	Logical AND
∨	Logical OR
⊕	Logical exclusive OR
→	Move
~	NOT (logical complement)
:8/:16/:24/:32	8-, 16-, 24-, or 32-bit length

Note: * General registers include 8-bit registers (R0H to R7H, R0L to R7L), 16-bit registers (R0 to R7, E0 to E7), and 32-bit registers (ER0 to ER7).

Table 2.3 Data Transfer Instructions

Instruction	Size*	Function
MOV	B/W/L	(EAs) → Rd, Rs → (EAd) Moves data between two general registers or between a general register and memory, or moves immediate data to a general register.
MOVFPE	B	Cannot be used in this LSI.
MOVTPE	B	Cannot be used in this LSI.
POP	W/L	@SP+ → Rn Pops a general register from the stack. POP.W Rn is identical to MOV.W @SP+, Rn. POP.L ERn is identical to MOV.L @SP+, ERn
PUSH	W/L	Rn → @-SP Pushes a general register onto the stack. PUSH.W Rn is identical to MOV.W Rn, @-SP. PUSH.L ERn is identical to MOV.L ERn, @-SP.
LDM	L	@SP+ → Rn (register list) Pops two or more general registers from the stack.
STM	L	Rn (register list) → @-SP Pushes two or more general registers onto the stack.

Note: * Size refers to the operand size.

B: Byte

W: Word

L: Longword

Table 2.4 Arithmetic Operations Instructions

Instruction	Size*1	Function
ADD SUB	B/W/L	$Rd \pm Rs \rightarrow Rd$, $Rd \pm \#IMM \rightarrow Rd$ Performs addition or subtraction on data in two general registers, or on immediate data and data in a general register. (Subtraction on immediate data and data in a general register cannot be performed in bytes. Use the SUBX or ADD instruction.)
ADDX SUBX	B	$Rd \pm Rs \pm C \rightarrow Rd$, $Rd \pm \#IMM \pm C \rightarrow Rd$ Performs addition or subtraction with carry on data in two general registers, or on immediate data and data in a general register.
INC DEC	B/W/L	$Rd \pm 1 \rightarrow Rd$, $Rd \pm 2 \rightarrow Rd$ Adds or subtracts the value 1 or 2 to or from data in a general register. (Only the value 1 can be added to or subtracted from byte operands.)
ADDS SUBS	L	$Rd \pm 1 \rightarrow Rd$, $Rd \pm 2 \rightarrow Rd$, $Rd \pm 4 \rightarrow Rd$ Adds or subtracts the value 1, 2, or 4 to or from data in a 32-bit register.
DAA DAS	B	Rd (decimal adjust) $\rightarrow Rd$ Decimal-adjusts an addition or subtraction result in a general register by referring to CCR to produce 4-bit BCD data.
MULXU	B/W	$Rd \times Rs \rightarrow Rd$ Performs unsigned multiplication on data in two general registers: either 8 bits \times 8 bits \rightarrow 16 bits or 16 bits \times 16 bits \rightarrow 32 bits.
MULXS	B/W	$Rd \times Rs \rightarrow Rd$ Performs signed multiplication on data in two general registers: either 8 bits \times 8 bits \rightarrow 16 bits or 16 bits \times 16 bits \rightarrow 32 bits.
DIVXU	B/W	$Rd \div Rs \rightarrow Rd$ Performs unsigned division on data in two general registers: either 16 bits \div 8 bits \rightarrow 8-bit quotient and 8-bit remainder or 32 bits \div 16 bits \rightarrow 16-bit quotient and 16-bit remainder.

Instruction	Size ^{*1}	Function
DIVXS	B/W	$Rd \div Rs \rightarrow Rd$ Performs signed division on data in two general registers: either 16 bits \div 8 bits \rightarrow 8-bit quotient and 8-bit remainder or 32 bits \div 16 bits \rightarrow 16-bit quotient and 16-bit remainder.
CMP	B/W/L	$Rd - Rs, Rd - \#IMM$ Compares data in a general register with data in another general register or with immediate data, and sets the CCR bits according to the result.
NEG	B/W/L	$0 - Rd \rightarrow Rd$ Takes the two's complement (arithmetic complement) of data in a general register.
EXTU	W/L	$Rd \text{ (zero extension)} \rightarrow Rd$ Extends the lower 8 bits of a 16-bit register to word size, or the lower 16 bits of a 32-bit register to longword size, by padding with zeros on the left.
EXTS	W/L	$Rd \text{ (sign extension)} \rightarrow Rd$ Extends the lower 8 bits of a 16-bit register to word size, or the lower 16 bits of a 32-bit register to longword size, by extending the sign bit.
TAS ^{*2}	B	$@ERd - 0, 1 \rightarrow (<\text{bit } 7> \text{ of } @ERd)$ Tests memory contents, and sets the most significant bit (bit 7) to 1.

Notes: ^{*1} Size refers to the operand size.

B: Byte

W: Word

L: Longword

^{*2} Only register ER0, ER1, ER4, or ER5 should be used when using the TAS instruction.

Table 2.5 Logic Operations Instructions

Instruction	Size*	Function
AND	B/W/L	$Rd \wedge Rs \rightarrow Rd, Rd \wedge \#IMM \rightarrow Rd$ Performs a logical AND operation on a general register and another general register or immediate data.
OR	B/W/L	$Rd \vee Rs \rightarrow Rd, Rd \vee \#IMM \rightarrow Rd$ Performs a logical OR operation on a general register and another general register or immediate data.
XOR	B/W/L	$Rd \oplus Rs \rightarrow Rd, Rd \oplus \#IMM \rightarrow Rd$ Performs a logical exclusive OR operation on a general register and another general register or immediate data.
NOT	B/W/L	$\sim Rd \rightarrow Rd$ Takes the one's complement (logical complement) of data in a general register.

Note: * Size refers to the operand size.

B: Byte

W: Word

L: Longword

Table 2.6 Shift Instructions

Instruction	Size*	Function
SHAL	B/W/L	$Rd \text{ (shift)} \rightarrow Rd$
SHAR		Performs an arithmetic shift on data in a general register. 1-bit or 2 bit shift is possible.
SHLL	B/W/L	$Rd \text{ (shift)} \rightarrow Rd$
SHLR		Performs a logical shift on data in a general register. 1-bit or 2 bit shift is possible.
ROTL	B/W/L	$Rd \text{ (rotate)} \rightarrow Rd$
ROTR		Rotates data in a general register. 1-bit or 2 bit rotation is possible.
ROTXL	B/W/L	$Rd \text{ (rotate)} \rightarrow Rd$
ROTXR		Rotates data including the carry flag in a general register. 1-bit or 2 bit rotation is possible.

Note: * Size refers to the operand size.

B: Byte

W: Word

L: Longword

Table 2.7 Bit Manipulation Instructions

Instruction	Size*	Function
BSET	B	$1 \rightarrow (\text{<bit-No.> of <EAd>})$ Sets a specified bit in a general register or memory operand to 1. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BCLR	B	$0 \rightarrow (\text{<bit-No.> of <EAd>})$ Clears a specified bit in a general register or memory operand to 0. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BNOT	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow (\text{<bit-No.> of <EAd>})$ Inverts a specified bit in a general register or memory operand. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BTST	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow Z$ Tests a specified bit in a general register or memory operand and sets or clears the Z flag accordingly. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BAND	B	$C \wedge (\text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ANDs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIAND	B	$C \wedge (\sim \text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ANDs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BOR	B	$C \vee (\text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIOR	B	$C \vee (\sim \text{<bit-No.> of <EAd>}) \rightarrow C$ Logically ORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.

Instruction	Size*	Function
BXOR	B	$C \oplus (\text{<bit-No.> of <EAd>}) \rightarrow C$ Logically exclusive-ORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIXOR	B	$C \oplus \sim (\text{<bit-No.> of <EAd>}) \rightarrow C$ Logically exclusive-ORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag. The bit number is specified by 3-bit immediate data.
BLD	B	$(\text{<bit-No.> of <EAd>}) \rightarrow C$ Transfers a specified bit in a general register or memory operand to the carry flag.
BILD	B	$\sim (\text{<bit-No.> of <EAd>}) \rightarrow C$ Transfers the inverse of a specified bit in a general register or memory operand to the carry flag. The bit number is specified by 3-bit immediate data.
BST	B	$C \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the carry flag value to a specified bit in a general register or memory operand.
BIST	B	$\sim C \rightarrow (\text{<bit-No.> of <EAd>})$ Transfers the inverse of the carry flag value to a specified bit in a general register or memory operand. The bit number is specified by 3-bit immediate data.

Note:* Size refers to the operand size.

B: Byte

Table 2.8 Branch Instructions

Instruction	Size	Function
Bcc	–	Branches to a specified address if a specified condition is true. The branching conditions are listed below.
Mnemonic	Description	Condition
BRA (BT)	Always (true)	Always
BRN (BF)	Never (false)	Never
BHI	High	$C \vee Z = 0$
BLS	Low or same	$C \vee Z = 1$
BCC (BHS)	Carry clear (high or same)	$C = 0$
BCS (BLO)	Carry set (low)	$C = 1$
BNE	Not equal	$Z = 0$
BEQ	Equal	$Z = 1$
BVC	Overflow clear	$V = 0$
BVS	Overflow set	$V = 1$
BPL	Plus	$N = 0$
BMI	Minus	$N = 1$
BGE	Greater or equal	$N \oplus V = 0$
BLT	Less than	$N \oplus V = 1$
BGT	Greater than	$Z \vee (N \oplus V) = 0$
BLE	Less or equal	$Z \vee (N \oplus V) = 1$
JMP	–	Branches unconditionally to a specified address.
BSR	–	Branches to a subroutine at a specified address.
JSR	–	Branches to a subroutine at a specified address.
RTS	–	Returns from a subroutine.

Table 2.9 System Control Instructions

Instruction	Size*	Function
TRAPA	–	Starts trap-instruction exception handling.
RTE	–	Returns from an exception-handling routine.
SLEEP	–	Causes a transition to a power-down state.
LDC	B/W	(EAs) → CCR, (EAs) → EXR Moves the memory operand contents or immediate data to CCR or EXR. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper 8 bits are valid.
STC	B/W	CCR → (EAd), EXR → (EAd) Transfers CCR or EXR contents to a general register or memory operand. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper 8 bits are valid.
ANDC	B	CCR ∧ #IMM → CCR, EXR ∧ #IMM → EXR Logically ANDs the CCR or EXR contents with immediate data.
ORC	B	CCR ∨ #IMM → CCR, EXR ∨ #IMM → EXR Logically ORs the CCR or EXR contents with immediate data.
XORC	B	CCR ⊕ #IMM → CCR, EXR ⊕ #IMM → EXR Logically exclusive-ORs the CCR or EXR contents with immediate data.
NOP	–	PC + 2 → PC Only increments the program counter.

Note:* Size refers to the operand size.

B: Byte

W: Word

Table 2.10 Block Data Transfer Instructions

Instruction	Size	Function
EEPMOV.B	–	if R4L \neq 0 then Repeat @ER5+ \rightarrow @ER6+ R4L–1 \rightarrow R4L Until R4L = 0 else next:
EEPMOV.W	–	if R4 \neq 0 then Repeat @ER5+ \rightarrow @ER6+ R4–1 \rightarrow R4 Until R4 = 0 else next: Transfers a data block. Starting from the address set in ER5, transfers data for the number of bytes set in R4L or R4 to the address location set in ER6. Execution of the next instruction begins as soon as the transfer is completed.

2.6.2 Basic Instruction Formats

The H8S/2000 CPU instructions consist of 2-byte (1-word) units. An instruction consists of an operation field (op), a register field (r), an effective address extension (EA), and a condition field (cc).

Figure 2.11 shows examples of instruction formats.

- **Operation field**
Indicates the function of the instruction, the addressing mode, and the operation to be carried out on the operand. The operation field always includes the first four bits of the instruction. Some instructions have two operation fields.
- **Register field**
Specifies a general register. Address registers are specified by 3 bits, and data registers by 3 bits or 4 bits. Some instructions have two register fields, and some have no register field.
- **Effective address extension**
8, 16, or 32 bits specifying immediate data, an absolute address, or a displacement.
- **Condition field**
Specifies the branching condition of Bcc instructions.

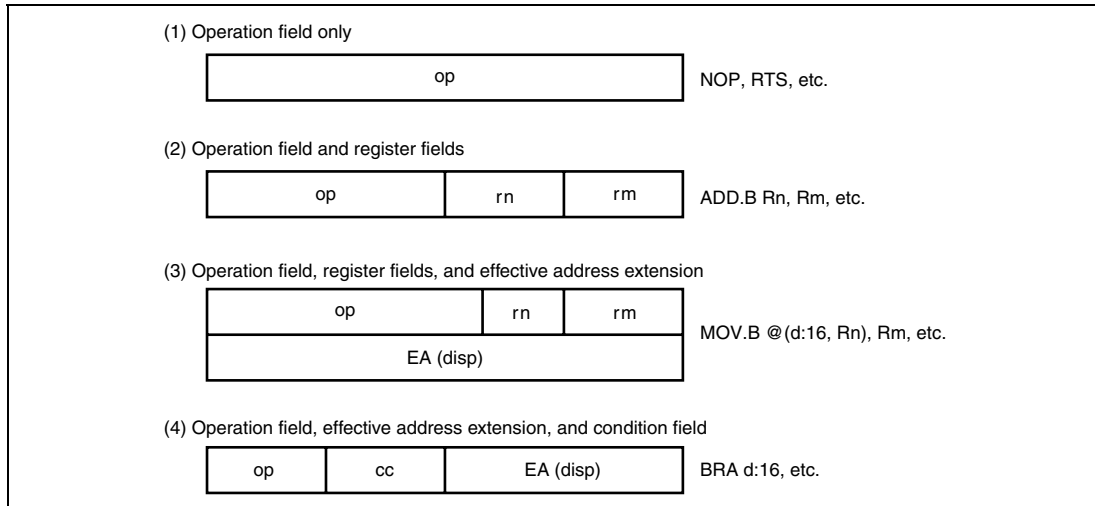

Figure 2.11 Instruction Formats (Examples)

2.7 Addressing Modes and Effective Address Calculation

The H8S/2000 CPU supports the eight addressing modes listed in table 2.11. Each instruction uses a subset of these addressing modes.

Arithmetic and logic operations instructions can use the register direct and immediate addressing modes. Data transfer instructions can use all addressing modes except program-counter relative and memory indirect. Bit manipulation instructions can use register direct, register indirect, or absolute addressing mode to specify an operand, and register direct (BSET, BCLR, BNOT, and BTST instructions) or immediate (3-bit) addressing mode to specify a bit number in the operand.

Table 2.11 Addressing Modes

No.	Addressing Mode	Symbol
1	Register direct	Rn
2	Register indirect	@ERn
3	Register indirect with displacement	@(d:16,ERn)/@(d:32,ERn)
4	Register indirect with post-increment	@ERn+
	Register indirect with pre-decrement	@-ERn
5	Absolute address	@aa:8/@aa:16/@aa:24/@aa:32
6	Immediate	#xx:8/#xx:16/#xx:32
7	Program-counter relative	@(d:8,PC)/@(d:16,PC)
8	Memory indirect	@@aa:8

2.7.1 Register Direct—Rn

The register field of the instruction code specifies an 8-, 16-, or 32-bit general register which contains the operand. R0H to R7H and R0L to R7L can be specified as 8-bit registers. R0 to R7 and E0 to E7 can be specified as 16-bit registers. ER0 to ER7 can be specified as 32-bit registers.

2.7.2 Register Indirect—@ERn

The register field of the instruction code specifies an address register (ERn) which contains the address of a memory operand. If the address is a program instruction address, the lower 24 bits are valid and the upper 8 bits are all assumed to be 0 (H'00).

2.7.3 Register Indirect with Displacement—@(d:16, ERn) or @(d:32, ERn)

A 16-bit or 32-bit displacement contained in the instruction code is added to an address register (ERn) specified by the register field of the instruction, and the sum gives the address of a memory operand. A 16-bit displacement is sign-extended when added.

2.7.4 Register Indirect with Post-Increment or Pre-Decrement—@ERn+ or @-ERn

Register Indirect with Post-Increment—@ERn+: The register field of the instruction code specifies an address register (ERn) which contains the address of a memory operand. After the operand is accessed, 1, 2, or 4 is added to the address register contents and the sum is stored in the address register. The value added is 1 for byte access, 2 for word access, and 4 for longword access. For word or longword transfer instructions, the register value should be even.

Register Indirect with Pre-Decrement—@-ERn: The value 1, 2, or 4 is subtracted from an address register (ERn) specified by the register field in the instruction code, and the result becomes the address of a memory operand. The result is also stored in the address register. The value subtracted is 1 for byte access, 2 for word access, and 4 for longword access. For word or longword transfer instructions, the register value should be even.

2.7.5 Absolute Address—@aa:8, @aa:16, @aa:24, or @aa:32

The instruction code contains the absolute address of a memory operand. The absolute address may be 8 bits long (@aa:8), 16 bits long (@aa:16), 24 bits long (@aa:24), or 32 bits long (@aa:32). Table 2.12 indicates the accessible absolute address ranges.

To access data, the absolute address should be 8 bits (@aa:8), 16 bits (@aa:16), or 32 bits (@aa:32) long. For an 8-bit absolute address, the upper 24 bits are all assumed to be 1 (H'FFFF). For a 16-bit absolute address, the upper 16 bits are a sign extension. For a 32-bit absolute address, the entire address space is accessed.

A 24-bit absolute address (@aa:24) indicates the address of a program instruction. The upper 8 bits are all assumed to be 0 (H'00).

Table 2.12 Absolute Address Access Ranges

Absolute Address		Normal Mode	Advanced Mode
Data address	8 bits (@aa:8)	H'FF00 to H'FFFF	H'FFFF00 to H'FFFFFF
	16 bits (@aa:16)	H'0000 to H'FFFF	H'000000 to H'007FFF, H'FF8000 to H'FFFFFF
	32 bits (@aa:32)		H'000000 to H'FFFFFF
Program instruction address	24 bits (@aa:24)		

2.7.6 Immediate—#xx:8, #xx:16, or #xx:32

The 8-bit (#xx:8), 16-bit (#xx:16), or 32-bit (#xx:32) immediate data contained in a instruction code can be used directly as an operand.

The ADDS, SUBS, INC, and DEC instructions implicitly contain immediate data in their instruction codes. Some bit manipulation instructions contain 3-bit immediate data in the instruction code, specifying a bit number. The TRAPA instruction contains 2-bit immediate data in its instruction code, specifying a vector address.

2.7.7 Program-Counter Relative—@(d:8, PC) or @(d:16, PC)

This mode can be used by the Bcc and BSR instructions. An 8-bit or 16-bit displacement contained in the instruction code is sign-extended to 24 bits and added to the 24-bit address indicated by the PC value to generate a 24-bit branch address. Only the lower 24 bits of this branch address are valid; the upper 8 bits are all assumed to be 0 (H'00). The PC value to which the displacement is added is the address of the first byte of the next instruction, so the possible branching range is –126 to +128 bytes (–63 to +64 words) or –32766 to +32768 bytes (–16383 to +16384 words) from the branch instruction. The resulting value should be an even number.

2.7.8 Memory Indirect—@@aa:8

This mode can be used by the JMP and JSR instructions. The instruction code contains an 8-bit absolute address specifying a memory operand which contains a branch address. The upper bits of the 8-bit absolute address are all assumed to be 0, so the address range is 0 to 255 (H'0000 to H'00FF in normal mode, H'000000 to H'0000FF in advanced mode).

In normal mode, the memory operand is a word operand and the branch address is 16 bits long. In advanced mode, the memory operand is a longword operand, the first byte of which is assumed to be 0 (H'00).

Note that the top area of the address range in which the branch address is stored is also used for the exception vector area. For further details, refer to section 4, Exception Handling.

If an odd address is specified in word or longword memory access, or as a branch address, the least significant bit is regarded as 0, causing data to be accessed or the instruction code to be fetched at the address preceding the specified address. (For further information, see section 2.5.2, Memory Data Formats.)

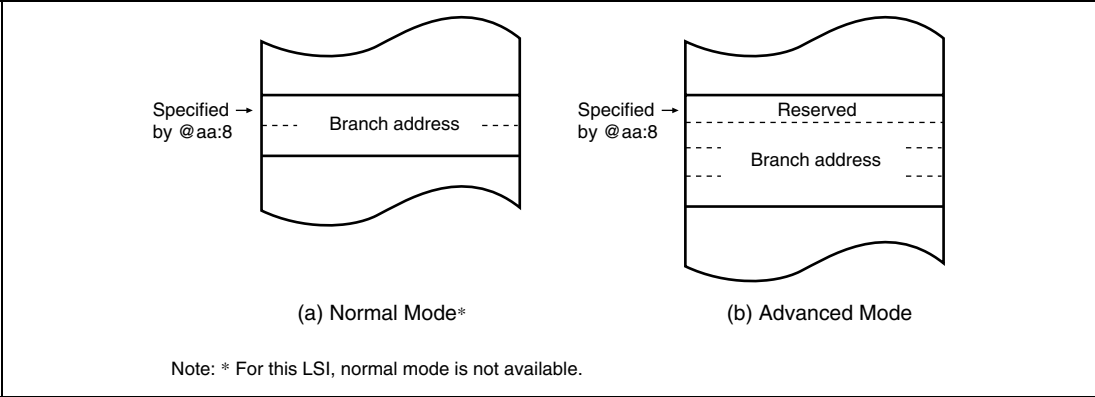

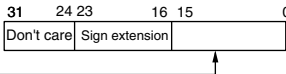

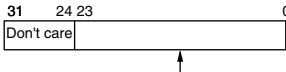

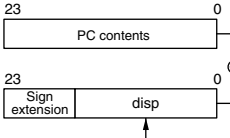

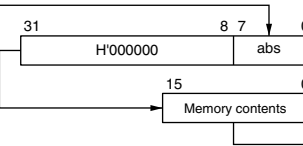

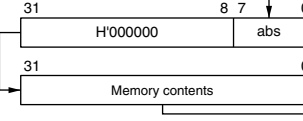

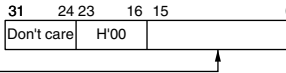

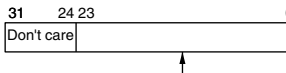

Figure 2.12 Branch Address Specification in Memory Indirect Addressing Mode

2.7.9 Effective Address Calculation

Table 2.13 indicates how effective addresses are calculated in each addressing mode. In normal mode, the upper 8 bits of the effective address are ignored in order to generate a 16-bit address.

Table 2.13 Effective Address Calculation

No	Addressing Mode and Instruction Format	Effective Address Calculation	Effective Address (EA)

Note: * For this LSI, normal mode is not available.

2.8 Processing States

The H8S/2000 CPU has five main processing states: the reset state, exception handling state, program execution state, bus-released state, and program stop state. Figure 2.13 indicates the state transitions.

- Reset state

In this state the CPU and internal peripheral modules are all initialized and stopped. When the $\overline{\text{RES}}$ input goes low, all current processing stops and the CPU enters the reset state. All interrupts are masked in the reset state. Reset exception handling starts when the $\overline{\text{RES}}$ signal changes from low to high. For details, refer to section 4, Exception Handling.

The reset state can also be entered by a watchdog timer overflow.

- Exception-handling state

The exception-handling state is a transient state that occurs when the CPU alters the normal processing flow due to an exception source, such as, a reset, trace, interrupt, or trap instruction. The CPU fetches a start address (vector) from the exception vector table and branches to that address. For further details, refer to section 4, Exception Handling.

- Program execution state

In this state the CPU executes program instructions in sequence.

- Bus-released state

In a product which has a DMA controller and a data transfer controller (DTC), the bus-released state occurs when the bus has been released in response to a bus request from a bus master other than the CPU. While the bus is released, the CPU halts operations.

- Program stop state

This is a power-down state in which the CPU stops operating. The program stop state occurs when a SLEEP instruction is executed or the CPU enters hardware standby mode. For details, refer to section 22, Power-Down Modes.

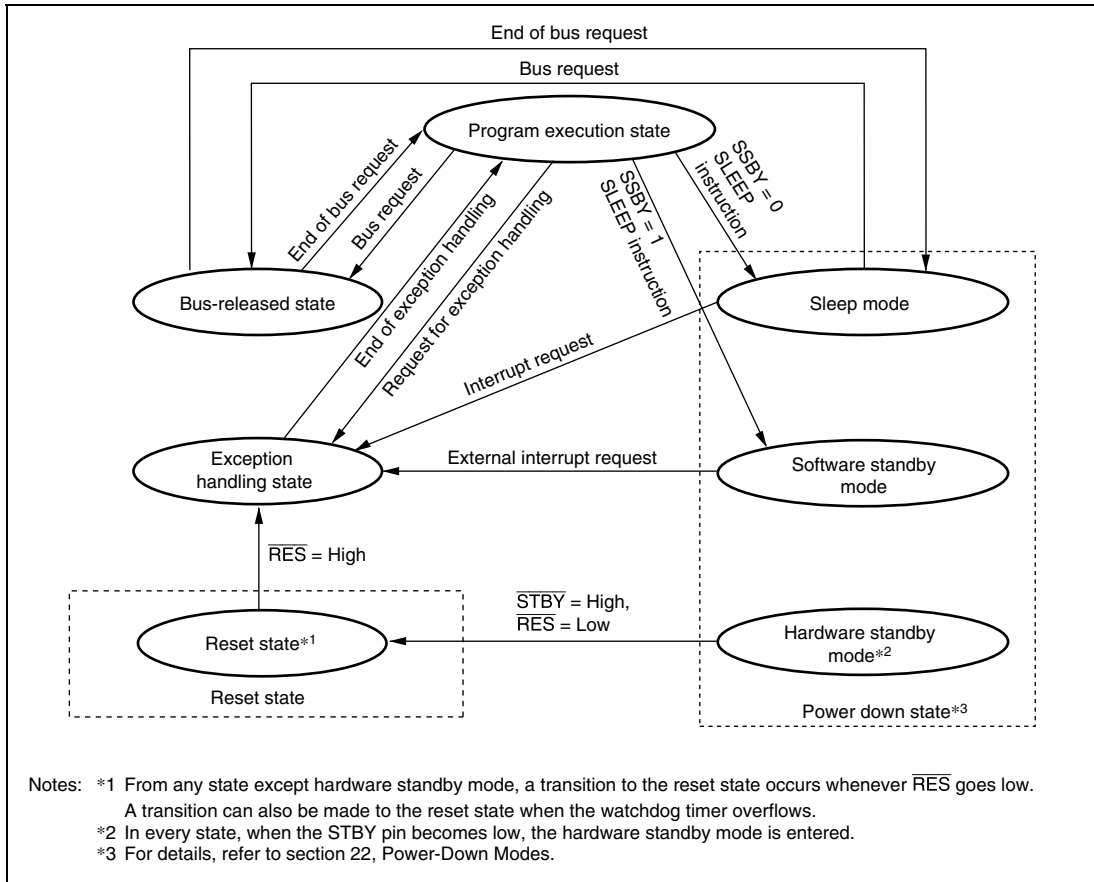

Figure 2.13 State Transitions

2.9 Usage Note

2.9.1 Note on Bit Manipulation Instructions

Bit manipulation instructions such as BSET, BCLR, BNOT, BST, and BIST read data in byte units, perform bit manipulation, and write data in byte units. Thus, care must be taken when these bit manipulation instructions are executed for a register or port including write-only bits.

In addition, the BCLR instruction can be used to clear the flag of an internal I/O register. In this case, if the flag to be cleared has been set by an interrupt processing routine, the flag need not be read before executing the BCLR instruction.

Section 3 MCU Operating Modes

3.1 Operating Mode Selection

This LSI has five operating modes (modes 1 to 4 and 7). Modes 1 to 4 and 7 are available in the flash memory version. Modes 1, 2, 4, and 7 are available in the masked ROM version. Modes 1 and 2 are available in the ROMless version. The operating mode is selected by the setting of mode pins (MD2 to MD0).

Modes 1, 2, and 4 are externally expanded modes in which the CPU can access an external memory and peripheral devices. In the externally expanded mode, each area can be switched to 8-bit or 16-bit address space by the bus controller. If any one of the areas is set to 16-bit address space, the bus mode is 16 bits. If all areas are set to 8-bit address space, the bus mode is 8 bits.

Mode 7 is a single-chip activation externally expanded mode in which the CPU can switch to access an external memory and peripheral devices at the beginning of a program execution.

Mode 3 is a boot mode in which the flash memory can be programmed or erased. For details on the boot mode, refer to section 19, Flash Memory (F-ZTAT Version).

Do not change the MD2 to MD0 pin settings during operation.

Table 3.1 MCU Operating Mode Selection

MCU Operating Mode	MD2	MD1	MD0	CPU Operating Mode	Description	On-Chip ROM	External Data Bus	
							Initial Width	Max. Value
1	0	0	1	Advanced	Expanded mode with on-chip ROM disabled	Disabled	16 bits	16 bits
2	0	1	0	Advanced	Expanded mode with on-chip ROM disabled	Disabled	8 bits	16 bits
3	0	1	1	Advanced	Boot mode	Enabled	—	16 bits
4	1	0	0	Advanced	Expanded mode with on-chip ROM enabled	Enabled	8 bits	16 bits
7	1	1	1	Advanced	Single-chip mode	Enabled	—	16 bits

3.2 Register Descriptions

The following registers are related to the operating mode.

- Mode control register (MDCR)
- System control register (SYSCR)

3.2.1 Mode Control Register (MDCR)

MDCR monitors the current operating mode of this LSI.

Bit	Bit Name	Initial Value	R/W	Descriptions
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	—	0	—	
4	—	0	—	
3	—	0	—	
2	MDS2	—*	R	Mode Select 2 to 0
1	MDS1	—*	R	These bits indicate the input levels at pins MD2 to MD0 (the current operating mode). Bits MDS2 to MDS0 correspond to MD2 to MD0. MDS2 to MDS0 are read-only bits and they cannot be written to. The mode pin (MD2 to MD0) input levels are latched into these bits when MDCR is read. These latches are canceled by a reset.
0	MDS0	—*	R	

Note: * Determined by pins MD2 to MD0.

3.2.2 System Control Register (SYSCR)

SYSCR controls CPU access to the flash memory control registers, sets external bus mode, and enables or disables on-chip RAM.

Bit	Bit Name	Initial Value	R/W	Descriptions
7	—	1	R/W	Reserved
6	—	1	R/W	The initial value should not be modified.
5	—	0	R/W	Reserved
4	—	0	R/W	The initial value should not be modified.
3	FLSHE	0	R/W	<p>Flash Memory Control Register Enable</p> <p>Controls CPU access to the flash memory control registers (FLMCR1, FLMCR2, EBR1, and EBR2). If this bit is set to 1, the flash memory control registers can be read/written to. If this bit is cleared to 0, the flash memory control registers are not selected. At this time, the contents of the flash memory control registers are maintained. This bit should be written to 0 in other than flash memory version.</p> <p>0: Flash memory control registers are not selected for area H'FFFFC8 to H'FFFFCB</p> <p>1: Flash memory control registers are selected for area H'FFFFC8 to H'FFFFCB</p>
2	—	0	—	<p>Reserved</p> <p>This bit is always read as 0 and cannot be modified.</p>
1	EXPE	—	R/W	<p>External Bus Mode Enable</p> <p>Sets external bus mode.</p> <p>In modes 1, 2, and 4, this bit is fixed at 1 and cannot be modified. In mode 3* and 7, this bit has an initial value of 0, and can be read and written.</p> <p>Writing of 0 to EXPE when its value is 1 should only be carried out when an external bus cycle is not being executed.</p> <p>0: External bus disabled</p> <p>1: External bus enabled</p>
0	RAME	1	R/W	<p>RAM Enable</p> <p>Enables or disables the on-chip RAM. The RAME bit is initialized when the reset status is released.</p> <p>0: On-chip RAM is disabled</p> <p>1: On-chip RAM is enabled</p>

3.3 Operating Mode Descriptions

3.3.1 Mode 1

The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is disabled. Ports A, B, and C function as an address bus, ports D and E function as a data bus, and parts of ports F, and G, carry bus control signals.

The initial bus mode after a reset is 16 bits, with 16-bit access to all areas. However, if 8-bit access is designated for all areas by the bus controller, the bus mode switches to 8 bits.

3.3.2 Mode 2

The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is disabled. Ports A, B, and C function as an address bus, ports D and E function as a data bus, and parts of ports F, and G carry bus control signals.

The initial bus mode after a reset is 8 bits, with 8-bit access to all areas. However, if 16-bit access is designated for any one of the areas by the bus controller, the bus mode switches to 16 bits and port E functions as a data bus.

3.3.3 Mode 3

This mode is a boot mode of the flash memory. This mode is the same as mode 7, except for the programming and erasure on the flash memory. Mode 3 is only available in the H8S/2368 Group flash memory version.

3.3.4 Mode 4

The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is enabled. The program in the on-chip ROM connected to the first half of area 0 is executed.

Ports A, B, and C function as input ports immediately after a reset, but can be set to function as an address bus. Ports D and E function as a data bus, and parts of ports F, and G, carry bus control signals. For details, see section 9, I/O Ports.

The initial bus mode after a reset is 8 bits, with 8-bit access to all areas. However, if 16-bit access is designated for any area by the bus controller, the bus mode switches to 16 bits and port E functions as a data bus.

In the flash memory version, user program mode is entered by setting the SWE bit of FLMCR1 to 1.

3.3.5 Mode 7

The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is enabled, and the chip starts up in single-chip mode. External address space cannot be used in single-chip mode.

The initial mode after a reset is single-chip mode, with all I/O ports available for use as input/output ports. However, the mode can be switched to externally expanded mode by setting 1 to the EXPE bit of SYSCR and then the external address space is enabled. When externally expanded mode is selected, all areas are initially designated as 16-bit access space. The functions of pins in ports A to G are the same as in externally expanded mode with on-chip ROM enabled.

In the flash memory version, user program mode is entered by setting the SWE bit of FLMCR1 to 1.

3.3.6 Pin Functions

Table 3.2 shows the pin functions in each operating mode.

Table 3.2 Pin Functions in Each Operating Mode

Port		Mode 1	Mode 2	Mode 3 ^{*2}	Mode 4 ^{*2}	Mode 7 ^{*2}
Port A	PA7 to PA5	P ^{*1} /A	P ^{*1} /A	P ^{*1} /A	P ^{*1} /A	P ^{*1} /A
	PA4 to PA0	A	A			
Port B		A	A	P ^{*1} /A	P ^{*1} /A	P ^{*1} /A
Port C		A	A	P ^{*1} /A	P ^{*1} /A	P ^{*1} /A
Port D		D	D	P ^{*1} /D	D	P ^{*1} /D
Port E		P/D ^{*1}	P ^{*1} /D	P ^{*1} /D	P ^{*1} /D	P ^{*1} /D
Port F	PF7, PF6	P/C ^{*1}	P ^{*1} /C	P ^{*1} /C	P/C ^{*1}	P ^{*1} /C
	PF5, PF4	C	C		C	
	PF3	P/C ^{*1}	P/C ^{*1}		P/C ^{*1}	
	PF2 to PF0	P ^{*1} /C	P ^{*1} /C		P ^{*1} /C

Section 4 Exception Handling

4.1 Exception Handling Types and Priority

As table 4.1 indicates, exception handling may be caused by a reset, trace, interrupt, or trap instruction. Exception handling is prioritized as shown in table 4.1. If two or more exceptions occur simultaneously, they are accepted and processed in order of priority. Exception sources, the stack structure, and operation of the CPU vary depending on the interrupt control mode. For details on the interrupt control mode, refer to section 5, Interrupt Controller.

Table 4.1 Exception Types and Priority

Priority	Exception Type	Start of Exception Handling
High 	Reset	Starts immediately after a low-to-high transition at the $\overline{\text{RES}}$ pin, or when the watchdog timer overflows. The CPU enters the reset state when the $\overline{\text{RES}}$ pin is low.
	Trace ^{*1}	Starts when execution of the current instruction or exception handling ends, if the trace (T) bit in the EXR is set to 1.
	Direct transition ^{*2}	Starts when the direct transition occurs by execution of the SLEEP instruction.
	Interrupt	Starts when execution of the current instruction or exception handling ends, if an interrupt request has been issued. ^{*3}
Low	Trap instruction ^{*4}	Started by execution of a trap instruction (TRAPA)

Notes: ^{*1} Traces are enabled only in interrupt control mode 2. Trace exception handling is not executed after execution of an RTE instruction.

^{*2} Not available in this LSI.

^{*3} Interrupt detection is not performed on completion of ANDC, ORC, XORC, or LDC instruction execution, or on completion of reset exception handling.

^{*4} Trap instruction exception handling requests are accepted at all times in program execution state.

4.2 Exception Sources and Exception Vector Table

Different vector addresses are assigned to different exception sources. Table 4.2 lists the exception sources and their vector addresses. Since the usable modes differ depending on the product, for details on each product, refer to section 3, MCU Operating Modes.

Table 4.2 Exception Handling Vector Table

Exception Source		Vector Number	Vector Address* ¹	
			Normal Mode* ²	Advanced Mode
Power-on reset		0	H'0000 to H'0001	H'0000 to H'0003
Manual reset * ³		1	H'0002 to H'0003	H'0004 to H'0007
Reserved for system use		2	H'0004 to H'0005	H'0008 to H'000B
		3	H'0006 to H'0007	H'000C to H'000F
		4	H'0008 to H'0019	H'0010 to H'0013
Trace		5	H'000A to H'000B	H'0014 to H'0017
Interrupt (direct transition)* ³		6	H'000C to H'000D	H'0018 to H'001B
Interrupt (NMI)		7	H'000E to H'000F	H'001C to H'001F
Trap instruction (#0)		8	H'0010 to H'0011	H'0020 to H'0023
	(#1)	9	H'0012 to H'0013	H'0024 to H'0027
	(#2)	10	H'0014 to H'0015	H'0028 to H'002B
	(#3)	11	H'0016 to H'0017	H'002C to H'002F
Reserved for system use		12	H'0018 to H'0019	H'0030 to H'0033
		13	H'001A to H'001B	H'0034 to H'0037
		14	H'001C to H'001D	H'0038 to H'003B
		15	H'001E to H'001F	H'003C to H'003F
External interrupt	IRQ0	16	H'0020 to H'0021	H'0040 to H'0043
	IRQ1	17	H'0022 to H'0023	H'0044 to H'0047
	IRQ2	18	H'0024 to H'0025	H'0048 to H'004B
	IRQ3	19	H'0026 to H'0027	H'004C to H'004F
	IRQ4	20	H'0028 to H'0029	H'0050 to H'0053
	IRQ5	21	H'002A to H'002B	H'0054 to H'0057
	IRQ6	22	H'002C to H'002D	H'0058 to H'005B
	IRQ7	23	H'002E to H'002F	H'005C to H'005F
Reserved for system use		24	H'0030 to H'0031	H'0060 to H'0063
		25	H'0032 to H'0033	H'0064 to H'0067
		26	H'0034 to H'0035	H'0068 to H'006B
		27	H'0036 to H'0037	H'006C to H'006F
		28	H'0038 to H'0039	H'0070 to H'0073
		29	H'003A to H'003B	H'0074 to H'0077
		30	H'003C to H'003D	H'0078 to H'007B
		31	H'003E to H'003F	H'007C to H'007F

Exception Source	Vector Number	Vector Address* ¹	
		Normal Mode* ²	Advanced Mode
Internal interrupt* ⁴	32	H'0040 to H'0041	H'0080 to H'0083
	118	H'00EC to H'00ED	H'01D8 to H'01DB

Notes: *1 Lower 16 bits of the address.

*2 Not available in this LSI.

*3 Not available in this LSI. It is reserved for system use.

*4 For details of internal interrupt vectors, see section 5.5, Interrupt Exception Handling Vector Table.

4.3 Reset

A reset has the highest exception priority. When the $\overline{\text{RES}}$ pin goes low, all processing halts and this LSI enters the reset. To ensure that this LSI is reset, hold the $\overline{\text{RES}}$ pin low for at least 20 ms at power-up. To reset the chip during operation, hold the $\overline{\text{RES}}$ pin low for at least 20 states. A reset initializes the internal state of the CPU and the registers of on-chip peripheral modules.

The chip can also be reset by overflow of the watchdog timer. For details see section 13, Watchdog Timer.

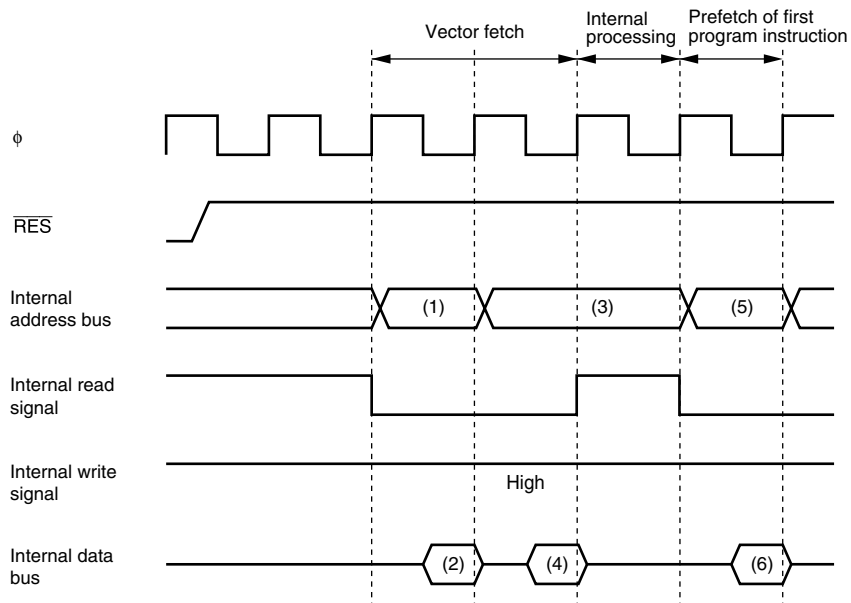

The interrupt control mode is 0 immediately after reset.

4.3.1 Reset Exception Handling

When the $\overline{\text{RES}}$ pin goes high after being held low for the necessary time, this LSI starts reset exception handling as follows:

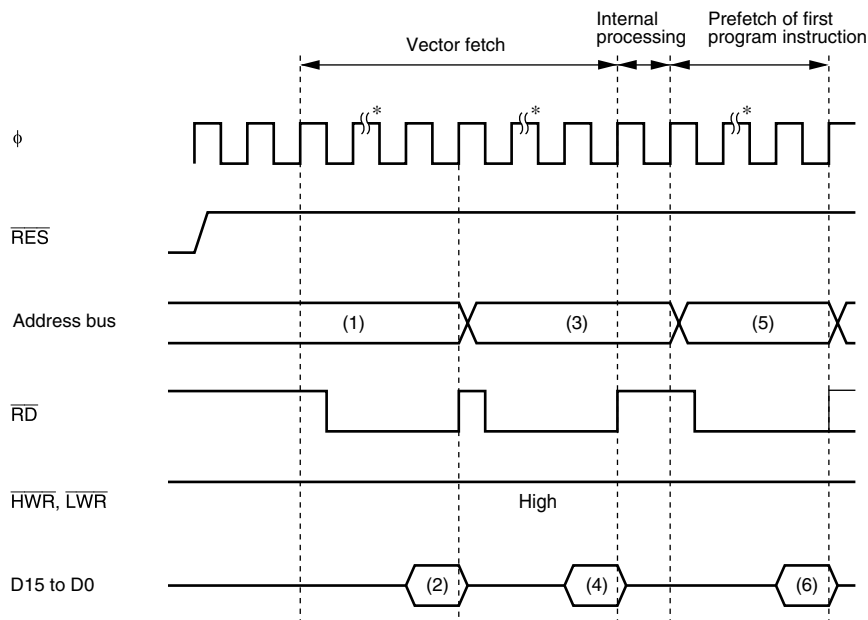

1. The internal state of the CPU and the registers of the on-chip peripheral modules are initialized, the T bit is cleared to 0 in EXR, and the I bit is set to 1 in EXR and CCR.
2. The reset exception handling vector address is read and transferred to the PC, and program execution starts from the address indicated by the PC.

Figures 4.1 and 4.2 show examples of the reset sequence.

- (1)(3) Reset exception handling vector address (when reset, (1)=H'000000, (3)=H'000002)
 (2)(4) Start address (contents of reset exception handling vector address)
 (5) Start address ((5)=(2)(4))
 (6) First program instruction

Figure 4.1 Reset Sequence (Advanced Mode with On-Chip ROM Enabled)

- (1)(3) Reset exception handling vector address (when reset, (1)=H'000000, (3)=H'000002)
 (2)(4) Start address (contents of reset exception handling vector address)
 (5) Start address ((5)=(2)(4))
 (6) First program instruction

Note: * Seven program wait states are inserted.

Figure 4.2 Reset Sequence (Advanced Mode with On-Chip ROM Disabled)

4.3.2 Interrupts after Reset

If an interrupt is accepted after a reset but before the stack pointer (SP) is initialized, the PC and CCR will not be saved correctly, leading to a program crash. To prevent this, all interrupt requests, including NMI, are disabled immediately after a reset. Since the first instruction of a program is always executed immediately after the reset state ends, make sure that this instruction initializes the stack pointer (example: `MOV.L #xx: 32, SP`).

4.3.3 On-Chip Peripheral Functions after Reset Release

After reset release, MSTPCR is initialized to H'0FFF and EXMSTPCR is to H'FFFD, all modules except the DMAC and the DTC enter module stop mode.

Consequently, on-chip peripheral module registers cannot be read from or written to. Register reading and writing is enabled when module stop mode is exited.

4.4 Traces

Traces are enabled in interrupt control mode 2. Trace mode is not activated in interrupt control mode 0, irrespective of the state of the T bit. For details on interrupt control modes, see section 5, Interrupt Controller.

If the T bit in EXR is set to 1, trace mode is activated. In trace mode, a trace exception occurs on completion of each instruction. Trace mode is not affected by interrupt masking. Table 4.3 shows the state of CCR and EXR after execution of trace exception handling. Trace mode is canceled by clearing the T bit in EXR to 0. The T bit saved on the stack retains its value of 1, and when control is returned from the trace exception handling routine by the RTE instruction, trace mode resumes. Trace exception handling is not carried out after execution of the RTE instruction.

Interrupts are accepted even within the trace exception handling routine.

Table 4.3 Status of CCR and EXR after Trace Exception Handling

Interrupt Control Mode	CCR		EXR	
	I	UI	I2 to I0	T
0	Trace exception handling cannot be used.			
2	1	—	—	0

Legend:

1: Set to 1

0: Cleared to 0

—: Retains value prior to execution.

4.5 Interrupts

Interrupts are controlled by the interrupt controller. The interrupt controller has two interrupt control modes and can assign interrupts other than NMI to eight priority/mask levels to enable multiplexed interrupt control. The source to start interrupt exception handling and the vector address differ depending on the product. For details, refer to section 5, Interrupt Controller.

The interrupt exception handling is as follows:

1. The values in the program counter (PC), condition code register (CCR), and extended register (EXR) are saved in the stack.
2. The interrupt mask bit is updated and the T bit is cleared to 0.
3. A vector address corresponding to the interrupt source is generated, the start address is loaded from the vector table to the PC, and program execution starts from that address.

4.6 Trap Instruction

Trap instruction exception handling starts when a TRAPA instruction is executed. Trap instruction exception handling can be executed at all times in the program execution state.

The trap instruction exception handling is as follows:

1. The values in the program counter (PC), condition code register (CCR), and extended register (EXR) are saved in the stack.
2. The interrupt mask bit is updated and the T bit is cleared to 0.
3. A vector address corresponding to the interrupt source is generated, the start address is loaded from the vector table to the PC, and program execution starts from that address.

The TRAPA instruction fetches a start address from a vector table entry corresponding to a vector number from 0 to 3, as specified in the instruction code.

Table 4.4 shows the status of CCR and EXR after execution of trap instruction exception handling.

Table 4.4 Status of CCR and EXR after Trap Instruction Exception Handling

Interrupt Control Mode	CCR		EXR	
	I	UI	I2 to I0	T
0	1	—	—	—
2	1	—	—	0

Legend:

- 1: Set to 1
- 0: Cleared to 0
- : Retains value prior to execution.

4.7 Stack Status after Exception Handling

Figure 4.3 shows the stack after completion of trap instruction exception handling and interrupt exception handling.

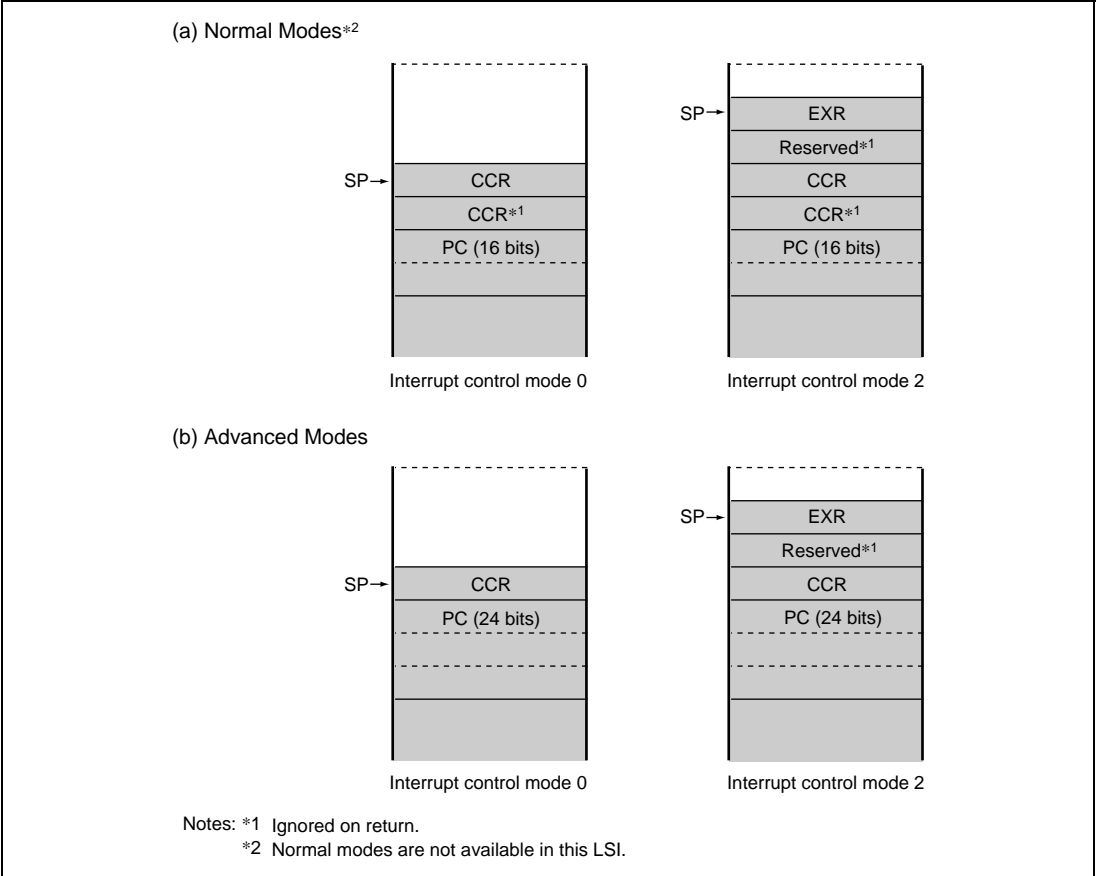

Figure 4.3 Stack Status after Exception Handling

4.8 Usage Notes

When accessing word data or longword data, this LSI assumes that the lowest address bit is 0. The stack should always be accessed by word transfer instruction or longword transfer instruction, and the value of the stack pointer (SP, ER7) should always be kept even. Use the following instructions to save registers:

```
PUSH.W   Rn      (or MOV.W Rn, @-SP)
PUSH.L   ERn     (or MOV.L ERn, @-SP)
```

Use the following instructions to restore registers:

```
POP.W    Rn      (or MOV.W @SP+, Rn)
POP.L    ERn     (or MOV.L @SP+, ERn)
```

Setting SP to an odd value may lead to a malfunction. Figure 4.4 shows an example of operation when the SP value is odd.

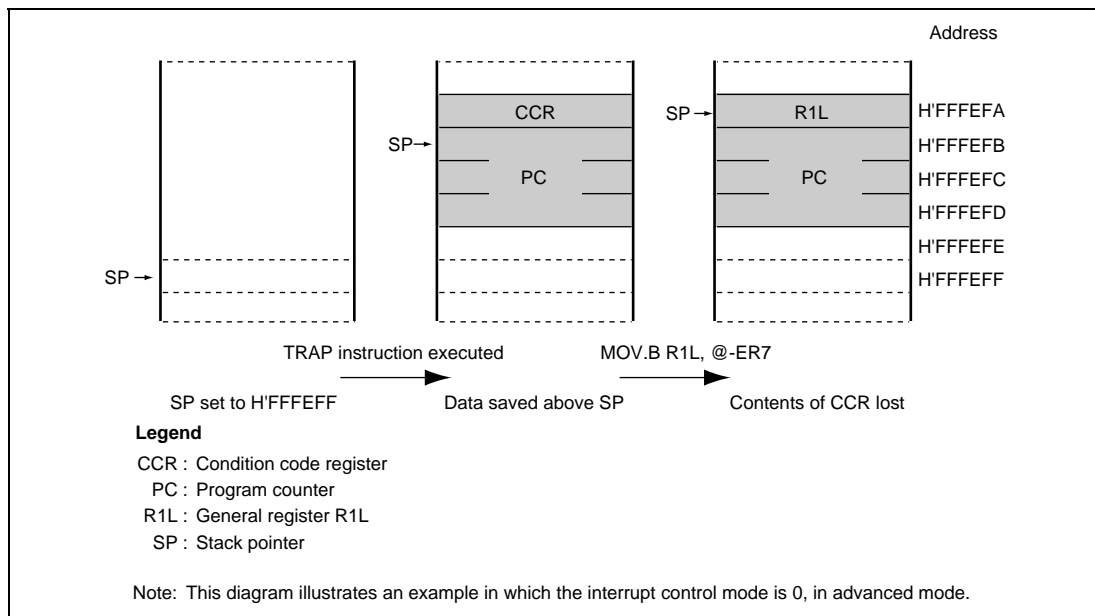

Figure 4.4 Operation when SP Value Is Odd

Section 5 Interrupt Controller

5.1 Features

- Two interrupt control modes

Any of two interrupt control modes can be set by means of the INTM1 and INTM0 bits in the interrupt control register (INTCR).

- Priorities settable with IPR

An interrupt priority register (IPR) is provided for setting interrupt priorities. Eight priority levels can be set for each module for all interrupts except NMI. NMI is assigned the highest priority level of 8, and can be accepted at all times.

- Independent vector addresses

All interrupt sources are assigned independent vector addresses, making it unnecessary for the source to be identified in the interrupt handling routine.

- Nine external interrupts

NMI is the highest-priority interrupt, and is accepted at all times. Rising edge or falling edge can be selected for NMI. Falling-edge, rising-edge, or both-edge detection, or level sensing, can be selected for $\overline{\text{IRQ7}}$ to $\overline{\text{IRQ0}}$.

- DTC and DMAC* control

DTC and DMAC* activations are performed by means of interrupts.

Note: * Not supported by the H8S/2366.

A block diagram of the interrupt controller is shown in figure 5.1.

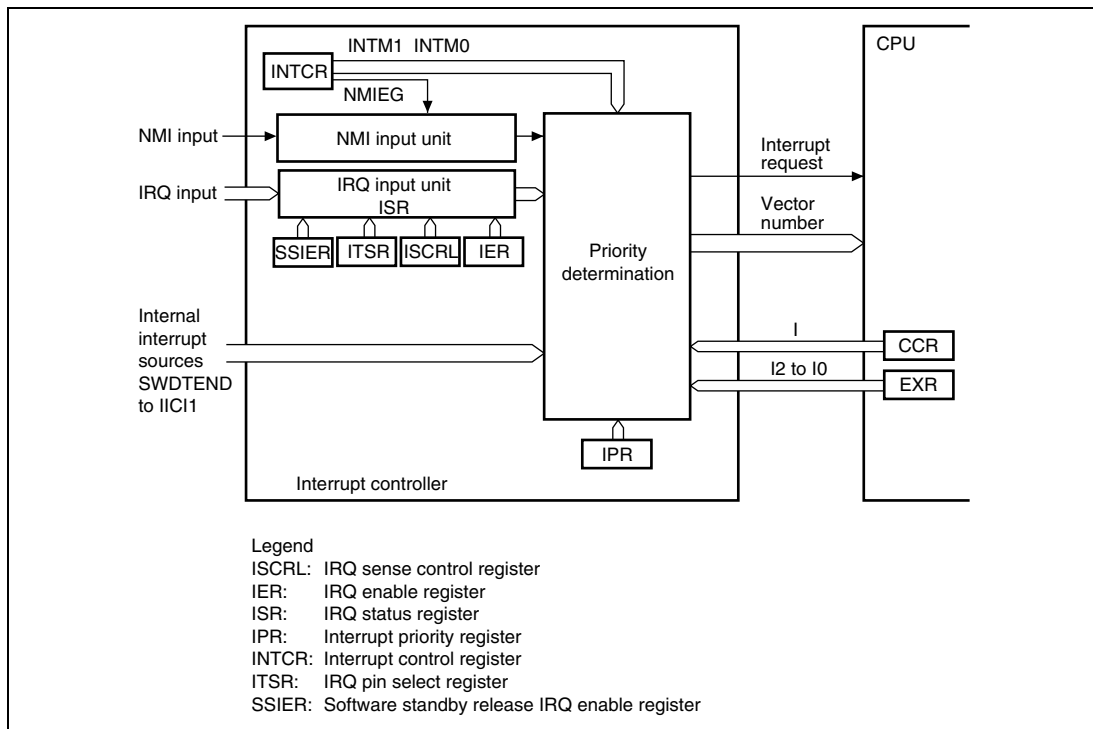

Figure 5.1 Block Diagram of Interrupt Controller

5.2 Input/Output Pins

Table 5.1 summarizes the pins of the interrupt controller.

Table 5.1 Pin Configuration

Name	I/O	Function
NMI	Input	Nonmaskable external interrupt Rising or falling edge can be selected.
IRQ7 to IRQ0	Input	Maskable external interrupts Rising edge, falling edge, both edges, or level sensing, can be selected.

5.3 Register Descriptions

The interrupt controller has the following registers.

- Interrupt control register (INTCR)
- IRQ sense control register L (ISCRL)
- IRQ enable register (IER)
- IRQ status register (ISR)
- IRQ pin select register (ITSR)
- Software standby release IRQ enable register (SSIER)
- Interrupt priority register A (IPRA)
- Interrupt priority register B (IPRB)
- Interrupt priority register C (IPRC)
- Interrupt priority register D (IPRD)
- Interrupt priority register E (IPRE)
- Interrupt priority register F (IPRF)
- Interrupt priority register G (IPRG)
- Interrupt priority register H (IPRH)
- Interrupt priority register I (IPRI)
- Interrupt priority register J (IPRJ)
- Interrupt priority register K (IPRK)

5.3.1 Interrupt Control Register (INTCR)

INTCR selects the interrupt control mode, and the detected edge for NMI.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0		These bits are always read as 0 and cannot be modified.
5	INTM1	0	R/W	Interrupt Control Select Mode 1 and 0
4	INTM0	0	R/W	These bits select either of two interrupt control modes for the interrupt controller. 00: Interrupt control mode 0 Interrupts are controlled by I bit. 01: Setting prohibited. 10: Interrupt control mode 2 Interrupts are controlled by bits I2 to I0, and IPR. 11: Setting prohibited.
3	NMIEG	0	R/W	NMI Edge Select Selects the input edge for the NMI pin. 0: Interrupt request generated at falling edge of NMI input 1: Interrupt request generated at rising edge of NMI input
2 to 0	—	0	—	Reserved These bits are always read as 0 and cannot be modified.

5.3.2 Interrupt Priority Registers A to K (IPRA to IPRK)

IPR are eleven 16-bit readable/writable registers that set priorities (levels 7 to 0) for interrupts other than NMI.

The correspondence between interrupt sources and IPR settings is shown in table 5.2. Setting a value in the range from H'0 to H'7 in the 3-bit groups of bits 14 to 12, 10 to 8, 6 to 4, and 2 to 0 sets the priority of the corresponding interrupt. IPR should be read in word size.

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	—	Reserved This bit is always read as 0 and cannot be modified.
14	IPR14	1	R/W	Sets the priority of the corresponding interrupt source. 000: Priority level 0 (Lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (Highest)
13	IPR13	1	R/W	
12	IPR12	1	R/W	
11	—	0	—	Reserved This bit is always read as 0 and cannot be modified.
10	IPR10	1	R/W	Sets the priority of the corresponding interrupt source. 000: Priority level 0 (Lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (Highest)
9	IPR9	1	R/W	
8	IPR8	1	R/W	
7	—	0	—	Reserved This bit is always read as 0 and cannot be modified.
6	IPR6	1	R/W	Sets the priority of the corresponding interrupt source. 000: Priority level 0 (Lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (Highest)
5	IPR5	1	R/W	
4	IPR4	1	R/W	

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	—	Reserved This bit is always read as 0 and cannot be modified.
2	IPR2	1	R/W	Sets the priority of the corresponding interrupt source. 000: Priority level 0 (Lowest) 001: Priority level 1 010: Priority level 2 011: Priority level 3 100: Priority level 4 101: Priority level 5 110: Priority level 6 111: Priority level 7 (Highest)
1	IPR1	1	R/W	
0	IPR0	1	R/W	

5.3.3 IRQ Enable Register (IER)

IER controls enabling and disabling of interrupt requests IRQ7 to IRQ0.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	0	R/W	Reserved The write value should always be 0.
7	IRQ7E	0	R/W	IRQ7 Enable The IRQ7 interrupt request is enabled when this bit is 1.
6	IRQ6E	0	R/W	IRQ6 Enable The IRQ6 interrupt request is enabled when this bit is 1.
5	IRQ5E	0	R/W	IRQ5 Enable The IRQ5 interrupt request is enabled when this bit is 1.
4	IRQ4E	0	R/W	IRQ4 Enable The IRQ4 interrupt request is enabled when this bit is 1.
3	IRQ3E	0	R/W	IRQ3 Enable The IRQ3 interrupt request is enabled when this bit is 1.

Bit	Bit Name	Initial Value	R/W	Description
2	IRQ2E	0	R/W	IRQ2 Enable The IRQ2 interrupt request is enabled when this bit is 1.
1	IRQ1E	0	R/W	IRQ1 Enable The IRQ1 interrupt request is enabled when this bit is 1.
0	IRQ0E	0	R/W	IRQ0 Enable The IRQ0 interrupt request is enabled when this bit is 1.

5.3.4 IRQ Sense Control Register L (ISCRL)

ISCRL select the source that generates an interrupt request at pins $\overline{\text{IRQ7}}$ to $\overline{\text{IRQ0}}$.

Bit	Bit Name	Initial Value	R/W	Description
15	IRQ7SCB	0	R/W	IRQ7 Sense Control B
14	IRQ7SCA	0	R/W	IRQ7 Sense Control A 00: Interrupt request generated at $\overline{\text{IRQ7}}$ input low level 01: Interrupt request generated at falling edge of $\overline{\text{IRQ7}}$ input 10: Interrupt request generated at rising edge of $\overline{\text{IRQ7}}$ input 11: Interrupt request generated at both falling and rising edges of $\overline{\text{IRQ7}}$ input
13	IRQ6SCB	0	R/W	IRQ6 Sense Control B
12	IRQ6SCA	0	R/W	IRQ6 Sense Control A 00: Interrupt request generated at $\overline{\text{IRQ6}}$ input low level 01: Interrupt request generated at falling edge of $\overline{\text{IRQ6}}$ input 10: Interrupt request generated at rising edge of $\overline{\text{IRQ6}}$ input 11: Interrupt request generated at both falling and rising edges of $\overline{\text{IRQ6}}$ input

Bit	Bit Name	Initial Value	R/W	Description
11	IRQ5SCB	0	R/W	IRQ5 Sense Control B
10	IRQ5SCA	0	R/W	IRQ5 Sense Control A

5.3.5 IRQ Status Register (ISR)

ISR is an IRQ7 to IRQ0 interrupt request flag register.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	–	0	R/W	Reserved The write value should always be 0.
7	IRQ7F	0	R/(W)*	[Setting conditions]
6	IRQ6F	0	R/(W)*	When the interrupt source selected by ISCR occurs
5	IRQ5F	0	R/(W)*	
4	IRQ4F	0	R/(W)*	[Clearing conditions]
3	IRQ3F	0	R/(W)*	
2	IRQ2F	0	R/(W)*	<ul style="list-style-type: none"> Cleared by reading IRQnF flag when IRQnF = 1, then writing 0 to IRQnF flag When interrupt exception handling is executed when low-level detection is set and $\overline{\text{IRQn}}$ input is high When IRQn interrupt exception handling is executed when falling, rising, or both-edge detection is set When the DTC is activated by an IRQn interrupt, and the DISEL bit in MRB of the DTC is cleared to 0
1	IRQ1F	0	R/(W)*	
0	IRQ0F	0	R/(W)*	

Note: * Only 0 can be written, to clear the flag.

5.3.6 IRQ Pin Select Register (ITSR)

ITSR selects input pins $\overline{\text{IRQ7}}$ to $\overline{\text{IRQ0}}$.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	–	0	R/W	Reserved The write value should always be 0.
7	ITS7	0	R/W	Selects $\overline{\text{IRQ7}}$ input pin. 0: PA7 1: P47
6	ITS6	0	R/W	Selects $\overline{\text{IRQ6}}$ input pin. 0: PA6 1: P46
5	ITS5	0	R/W	Selects $\overline{\text{IRQ5}}$ input pin. 0: PA5 1: P45
4	ITS4	0	R/W	Selects $\overline{\text{IRQ4}}$ input pin. 0: PA4 1: P44
3	ITS3	0	R/W	Selects $\overline{\text{IRQ3}}$ input pin. 0: P53 1: P43
2	ITS2	0	R/W	Selects $\overline{\text{IRQ2}}$ input pin. 0: P52 1: P42
1	ITS1	0	R/W	Selects $\overline{\text{IRQ1}}$ input pin. 0: P51 1: P41
0	ITS0	0	R/W	Selects $\overline{\text{IRQ0}}$ input pin. 0: P50 1: P40

5.3.7 Software Standby Release IRQ Enable Register (SSIER)

SSIER selects the $\overline{\text{IRQ}}$ pins used to recover from the software standby state.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	–	0	R/W	Reserved The write value should always be 0.
7	SSI7	0	R/W	Software Standby Release IRQ Setting
6	SSI6	0	R/W	These bits select the $\overline{\text{IRQn}}$ pins used to recover from the software standby state.
5	SSI5	0	R/W	
4	SSI4	0	R/W	0: IRQn requests are not sampled in the software standby state (Initial value when n = 7 to 3)
3	SSI3	0	R/W	
2	SSI2	0	R/W	1: When an IRQn request occurs in the software standby state, the chip recovers from the software standby state after the elapse of the oscillation settling time (Initial value when n = 2 to 0)
1	SSI1	0	R/W	
0	SSI0	0	R/W	

5.4 Interrupt Sources

5.4.1 External Interrupts

There are nine external interrupts: NMI and IRQ7 to IRQ0. These interrupts can be used to restore the chip from software standby mode.

NMI Interrupt: Nonmaskable interrupt request (NMI) is the highest-priority interrupt, and is always accepted by the CPU regardless of the interrupt control mode or the status of the CPU interrupt mask bits. The NMIEG bit in INTCR can be used to select whether an interrupt is requested at a rising edge or a falling edge on the NMI pin.

IRQ7 to IRQ0 Interrupts: Interrupts IRQ7 to IRQ0 are requested by an input signal at pins $\overline{\text{IRQ7}}$ to $\overline{\text{IRQ0}}$. Interrupts IRQ7 to IRQ0 have the following features:

- Using ISCRL, it is possible to select whether an interrupt is generated by a low level, falling edge, rising edge, or both edges, at pins $\overline{\text{IRQ7}}$ to $\overline{\text{IRQ0}}$.
- Enabling or disabling of interrupt requests IRQ7 to IRQ0 can be selected with IER.
- The interrupt priority level can be set with IPR.
- The status of interrupt requests IRQ7 to IRQ0 is indicated in ISR. ISR flags can be cleared to 0 by software.

When IRQ7 to IRQ0 interrupt requests occur at low level of $\overline{\text{IRQn}}$, the corresponding $\overline{\text{IRQ}}$ should be held low until an interrupt handling starts. Then the corresponding $\overline{\text{IRQ}}$ should be set to high in the interrupt handling routine and clear the IRQnF bit (n = 0 to 7) in ISR to 0. Interrupts may not be executed when the corresponding $\overline{\text{IRQ}}$ is set to high before the interrupt handling starts.

Detection of IRQ7 to IRQ0 interrupts does not depend on whether the relevant pin has been set for input or output. However, when a pin is used as an external interrupt input pin, do not clear the corresponding DDR to 0 and use the pin as an I/O pin for another function.

A block diagram of interrupts IRQ7 to IRQ0 is shown in figure 5.2.

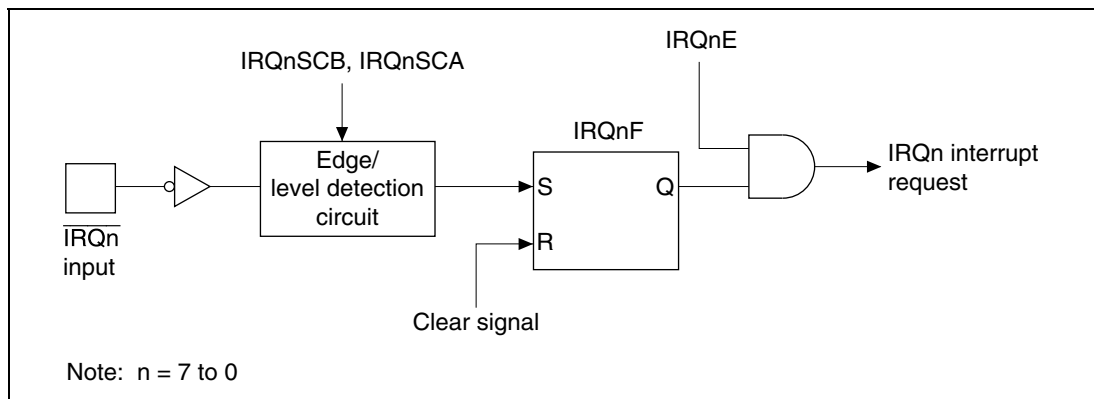

Figure 5.2 Block Diagram of Interrupts IRQ15 to IRQ0

5.4.2 Internal Interrupts

The sources for internal interrupts from on-chip peripheral modules have the following features:

- For each on-chip peripheral module there are flags that indicate the interrupt request status, and enable bits that select enabling or disabling of these interrupts. They can be controlled independently. When the enable bit is set to 1, an interrupt request is issued to the interrupt controller.
- The interrupt priority level can be set by means of IPR.
- The DMAC* and DTC can be activated by a TPU, SCI, or other interrupt request.
- When the DMAC* or DTC is activated by an interrupt request, it is not affected by the interrupt control mode or CPU interrupt mask bit.

Note: * Not supported by the H8S/2366.

5.5 Interrupt Exception Handling Vector Table

Table 5.2 shows interrupt exception handling sources, vector addresses, and interrupt priorities.

For default priorities, the lower the vector number, the higher the priority. When interrupt control mode 2 is set, priorities among modules can be set by means of the IPR. Modules set at the same priority will conform to their default priorities. Priorities within a module are fixed.

Table 5.2 Interrupt Sources, Vector Addresses, and Interrupt Priorities

Notes: *1 Lower 16 bits of the start address.

*2 Not supported by the H8S/2366.

5.6 Interrupt Control Modes and Interrupt Operation

The interrupt controller has two modes: interrupt control mode 0 and interrupt control mode 2. Interrupt operations differ depending on the interrupt control mode. The interrupt control mode is selected by INTCR. Table 5.3 shows the differences between interrupt control mode 0 and interrupt control mode 2.

Table 5.3 Interrupt Control Modes

Interrupt Control Mode	Priority Setting Registers	Interrupt Mask Bits	Description
0	Default	I	The priorities of interrupt sources are fixed at the default settings. Interrupt sources except for NMI is masked by the I bit.
2	IPR	I2 to I0	8 priority levels except for NMI can be set with IPR. 8-level interrupt mask control is performed by bits I2 to I0.

5.6.1 Interrupt Control Mode 0

In interrupt control mode 0, interrupt requests except for NMI is masked by the I bit of CCR in the CPU. Figure 5.3 shows a flowchart of the interrupt acceptance operation in this case.

1. If an interrupt source occurs when the corresponding interrupt enable bit is set to 1, an interrupt request is sent to the interrupt controller.
2. If the I bit is set to 1, only an NMI interrupt is accepted, and other interrupt requests are held pending. If the I bit is cleared, an interrupt request is accepted.
3. Interrupt requests are sent to the interrupt controller, the highest-ranked interrupt according to the priority system is accepted, and other interrupt requests are held pending.
4. When the CPU accepts an interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
5. The PC and CCR are saved to the stack area by interrupt exception handling. The PC saved on the stack shows the address of the first instruction to be executed after returning from the interrupt handling routine.
6. Next, the I bit in CCR is set to 1. This masks all interrupts except NMI.
7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address in the vector table.

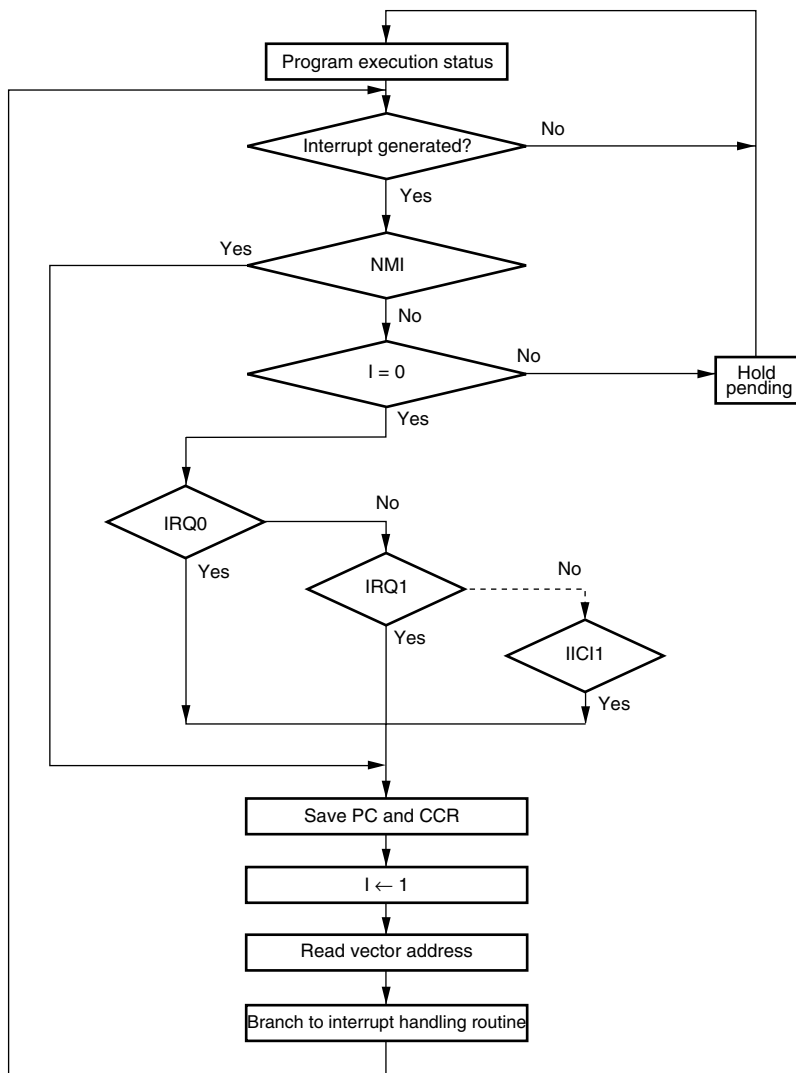

Figure 5.3 Flowchart of Procedure Up to Interrupt Acceptance in Interrupt Control Mode 0

5.6.2 Interrupt Control Mode 2

In interrupt control mode 2, mask control is done in eight levels for interrupt requests except for NMI by comparing the EXR interrupt mask level (I2 to I0 bits) in the CPU and the IPR setting. Figure 5.4 shows a flowchart of the interrupt acceptance operation in this case.

1. If an interrupt source occurs when the corresponding interrupt enable bit is set to 1, an interrupt request is sent to the interrupt controller.
2. When interrupt requests are sent to the interrupt controller, the interrupt with the highest priority according to the interrupt priority levels set in IPR is selected, and lower-priority interrupt requests are held pending. If a number of interrupt requests with the same priority are generated at the same time, the interrupt request with the highest priority according to the priority system shown in table 5.2 is selected.
3. Next, the priority of the selected interrupt request is compared with the interrupt mask level set in EXR. An interrupt request with a priority no higher than the mask level set at that time is held pending, and only an interrupt request with a priority higher than the interrupt mask level is accepted.
4. When the CPU accepts an interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
5. The PC, CCR, and EXR are saved to the stack area by interrupt exception handling. The PC saved on the stack shows the address of the first instruction to be executed after returning from the interrupt handling routine.
6. The T bit in EXR is cleared to 0. The interrupt mask level is rewritten with the priority level of the accepted interrupt.

If the accepted interrupt is NMI, the interrupt mask level is set to H'7.

7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address in the vector table.

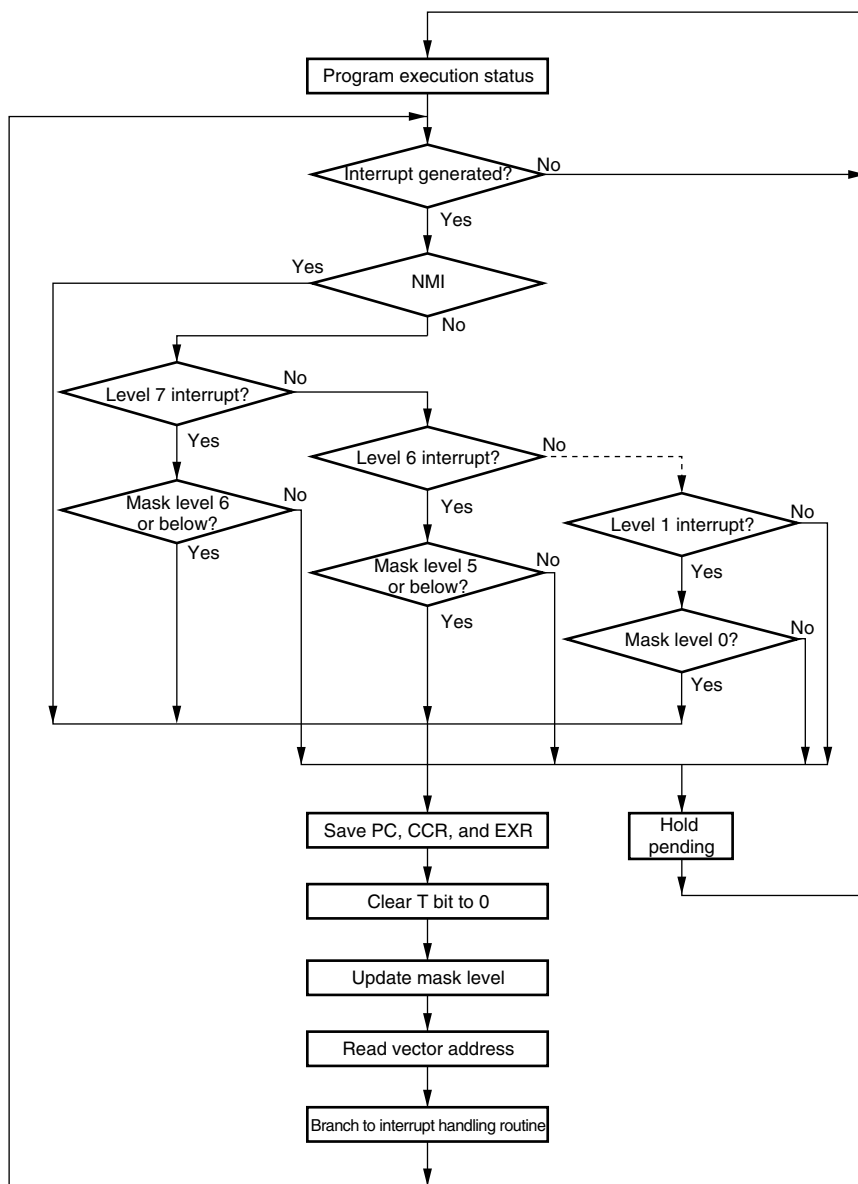

Figure 5.4 Flowchart of Procedure Up to Interrupt Acceptance in Interrupt Control Mode 2

5.6.3 Interrupt Exception Handling Sequence

Figure 5.5 shows the interrupt exception handling sequence. The example shown is for the case where interrupt control mode 0 is set in advanced mode, and the program area and stack area are in on-chip memory.

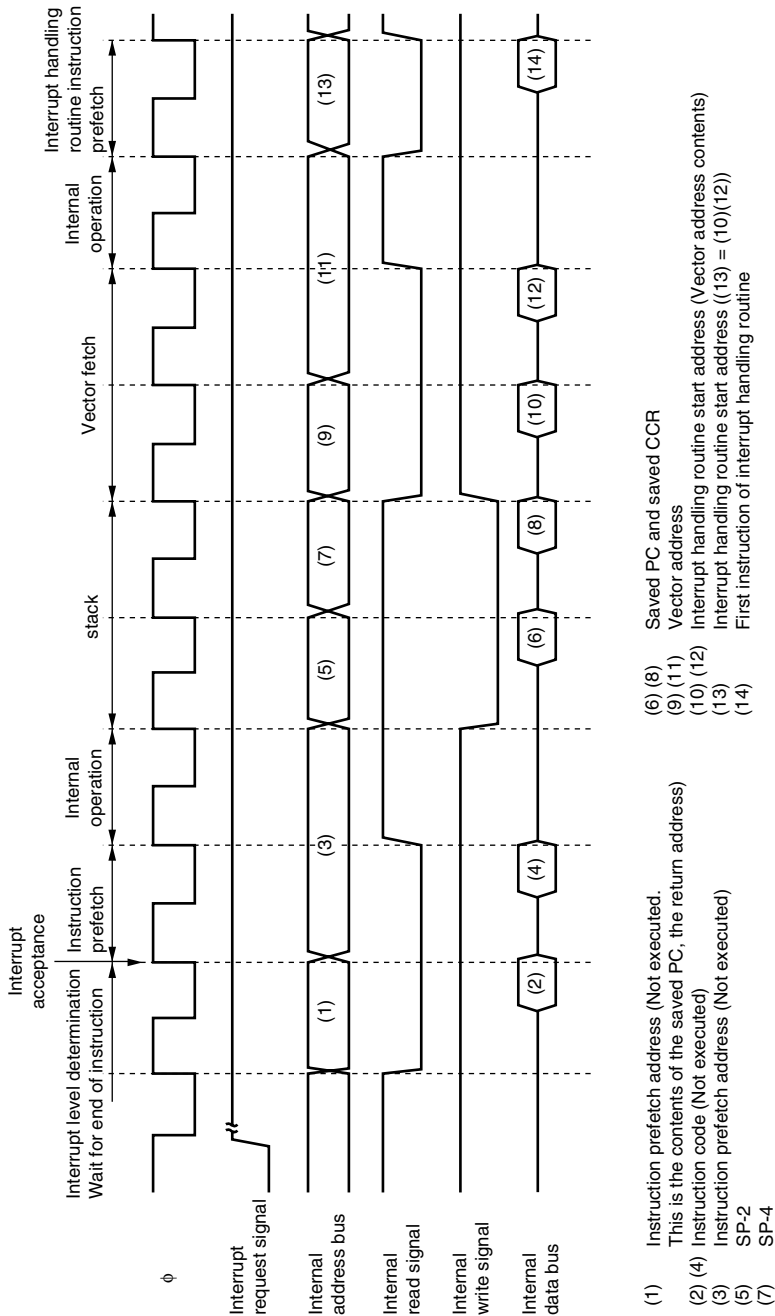

Figure 5.5 Interrupt Exception Handling

5.6.4 Interrupt Response Times

Table 5.4 shows interrupt response times - the interval between generation of an interrupt request and execution of the first instruction in the interrupt handling routine. The execution status symbols used in table 5.4 are explained in table 5.5.

This LSI is capable of fast word transfer to on-chip memory, and have the program area in on-chip ROM and the stack area in on-chip RAM, enabling high-speed processing.

Table 5.4 Interrupt Response Times

No.	Execution Status	Normal Mode* ⁵		Advanced Mode	
		Interrupt control mode 0	Interrupt control mode 2	Interrupt control mode 0	Interrupt control mode 2
1	Interrupt priority determination* ¹	3	3	3	3
2	Number of wait states until executing instruction ends* ²	1 to 19 + 2·S _I	1 to 19 + 2·S _I	1 to 19 + 2·S _I	1 to 19 + 2·S _I
3	PC, CCR, EXR stack save	2·S _K	3·S _K	2·S _K	3·S _K
4	Vector fetch	S _I	S _I	2·S _I	2·S _I
5	Instruction fetch* ³	2·S _I	2·S _I	2·S _I	2·S _I
6	Internal processing* ⁴	2	2	2	2
Total (using on-chip memory)		11 to 31	12 to 32	12 to 32	13 to 33

Notes: *1 Two states in case of internal interrupt.

*2 Refers to MULXS and DIVXS instructions.

*3 Prefetch after interrupt acceptance and interrupt handling routine prefetch.

*4 Internal processing after interrupt acceptance and internal processing after vector fetch.

*5 Not available in this LSI.

Table 5.5 Number of States in Interrupt Handling Routine Execution Statuses

Symbol	Internal Memory	Object of Access			
		External Device			
		8 Bit Bus		16 Bit Bus	
		2-State Access	3-State Access	2-State Access	3-State Access
Instruction fetch S _I	1	4	6+2m	2	3+m
Branch address read S _J					
Stack manipulation S _K					

Legend: m: Number of wait states in an external device access.

5.6.5 DTC and DMAC* Activation by Interrupt

The DTC and DMAC* can be activated by an interrupt. In this case, the following options are available:

- Interrupt request to CPU
- Activation request to DTC
- Activation request to DMAC*
- Selection of a number of the above

For details of interrupt requests that can be used to activate the DTC and DMAC*, see table 5.2 and section 8, Data Transfer Controller (DTC) and section 7, DMA Controller (DMAC)*.

Note: * Not supported by the H8S/2366.

5.7 Usage Notes

5.7.1 Contention between Interrupt Generation and Disabling

When an interrupt enable bit is cleared to 0 to mask interrupts, the masking becomes effective after execution of the instruction.

When an interrupt enable bit is cleared to 0 by an instruction such as BCLR or MOV, if an interrupt is generated during execution of the instruction, the interrupt concerned will still be enabled on completion of the instruction, and so interrupt exception handling for that interrupt will be executed on completion of the instruction. However, if there is an interrupt request of higher priority than that interrupt, interrupt exception handling will be executed for the higher-priority interrupt, and the lower-priority interrupt will be ignored. The same also applies when an interrupt source flag is cleared to 0. Figure 5.6 shows an example in which the TCIEV bit in the TPU's TIER_0 register is cleared to 0. The above contention will not occur if an enable bit or interrupt source flag is cleared to 0 while the interrupt is masked.

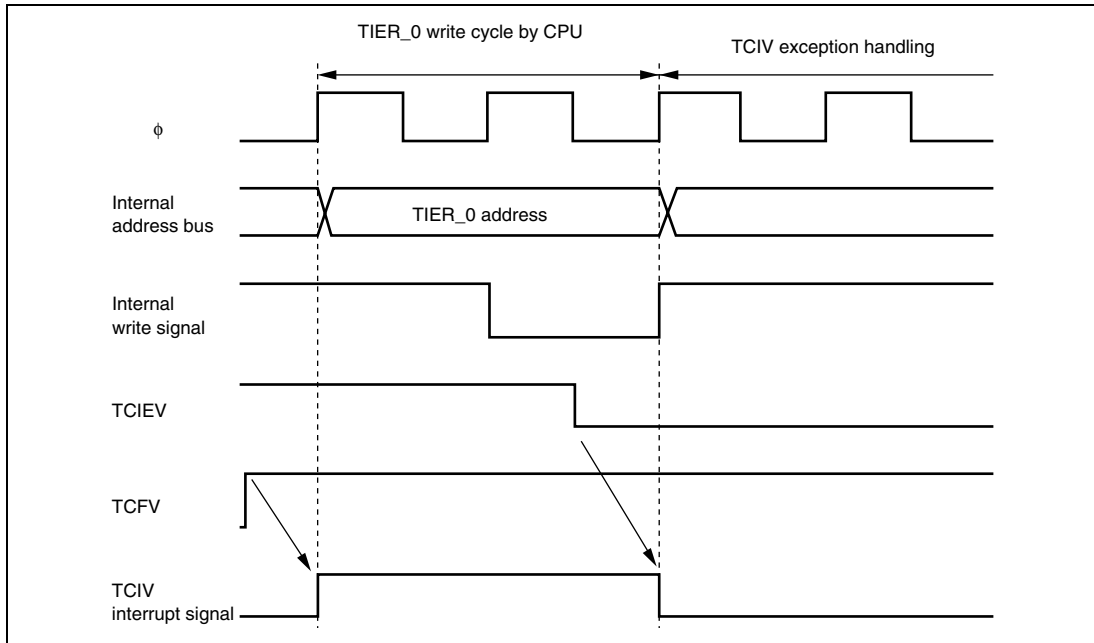

Figure 5.6 Contention between Interrupt Generation and Disabling

5.7.2 Instructions that Disable Interrupts

Instructions that disable interrupts are LDC, ANDC, ORC, and XORC. After any of these instructions is executed, all interrupts including NMI are disabled and the next instruction is always executed. When the I bit is set by one of these instructions, the new value becomes valid two states after execution of the instruction ends.

5.7.3 Times when Interrupts are Disabled

There are times when interrupt acceptance is disabled by the interrupt controller.

The interrupt controller disables interrupt acceptance for a 3-state period after the CPU has updated the mask level with an LDC, ANDC, ORC, or XORC instruction.

5.7.4 Interrupts during Execution of EEPMOV Instruction

Interrupt operation differs between the EEPMOV.B instruction and the EEPMOV.W instruction.

With the EEPMOV.B instruction, an interrupt request (including NMI) issued during the transfer is not accepted until the transfer is completed.

With the EEPMOV.W instruction, if an interrupt request is issued during the transfer, interrupt exception handling starts at a break in the transfer cycle. The PC value saved on the stack in this case is the address of the next instruction. Therefore, if an interrupt is generated during execution of an EEPMOV.W instruction, the following coding should be used.

```
L1:    EEPMOV.W
      MOV.W    R4, R4
      BNE      L1
```

5.7.5 Change of IRQ Pin Select Register (ITSR) Setting

When the ITSR setting is changed, an edge occurs internally and the IRQnF bit ($n = 0$ to 7) of ISR may be set to 1 at the unintended timing if the selected pin level before the change is different from the selected pin level after the change. If the IRQn interrupt request ($n = 0$ to 7) is enabled, the interrupt exception handling is executed. To prevent the unintended interrupt, ITSR setting should be changed while the IRQn interrupt request is disabled, then the IRQnF bit should be cleared to 0.

5.7.6 Note on IRQ Status Register (ISR)

Since IRQnF flags may be set to 1 depending on the pin states after a reset, be sure to read from ISR after a reset and then write 0 to clear the IRQnF flags.

Section 6 Bus Controller (BSC)

This LSI has an on-chip bus controller (BSC) that manages the external space divided into eight areas.

The bus controller also has a bus arbitration function, and controls the operation of the bus masters—the CPU, DMA controller (DMAC)* and data transfer controller (DTC).

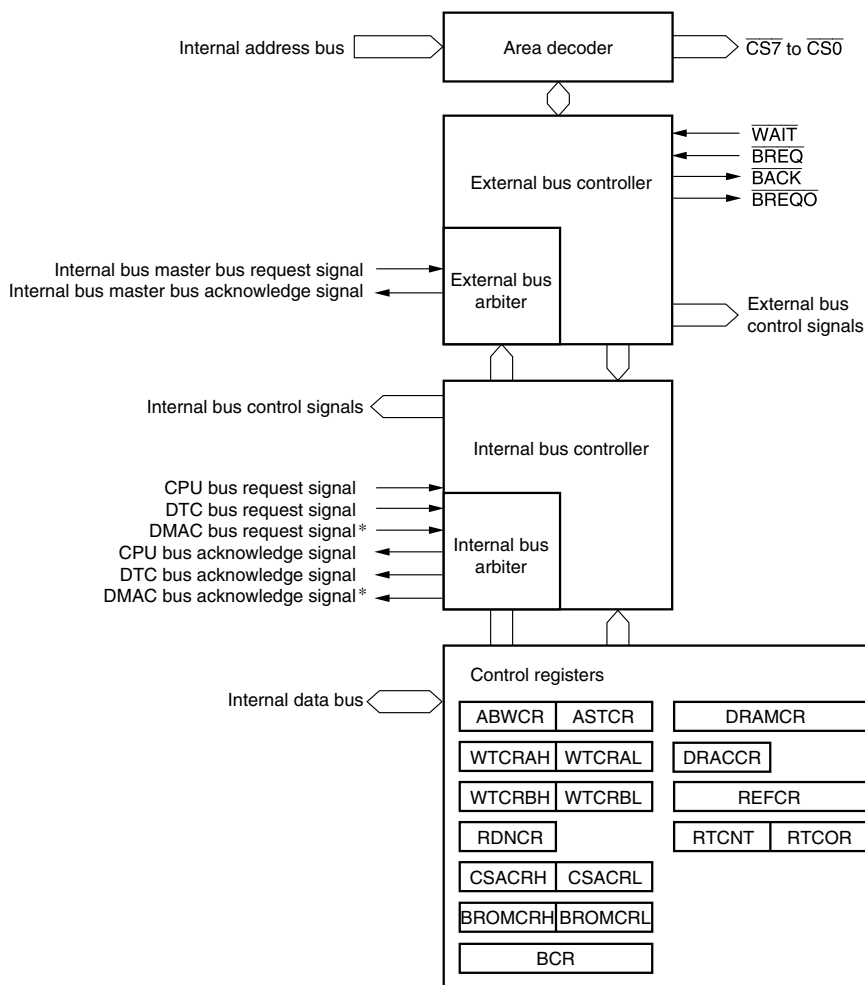

Note: * Not supported by the H8S/2366.

6.1 Features

- **Manages external space in area units**
Manages the external space divided into eight areas of 2 Mbytes
Bus specifications can be set independently for each area
Burst ROM, or DRAM*, interface can be set
- **Basic bus interface**
Chip select signals ($\overline{CS0}$ to $\overline{CS7}$) can be output for areas 0 to 7
8-bit access or 16-bit access can be selected for each area
2-state access or 3-state access can be selected for each area
Program wait states can be inserted for each area
- **Burst ROM interface**
Burst ROM interface can be set independently for areas 0 and 1
- **DRAM interface***
DRAM interface can be set for areas 2 to 5
- **Bus arbitration function**
Includes a bus arbiter that arbitrates bus right between the CPU, DMAC*, and DTC

Note: * Not supported by the H8S/2366.

A block diagram of the bus controller is shown in figure 6.1.

Legend

ABWCR	: Bus width control register	BROMCRL	: Area 1 burst ROM interface control register
ASTCR	: Access state control register	BCR	: Bus control register
WTCRAH, WTCRAL,		DRAMCR*	: DRAM control register
WTCRBH, and WTCRBL	: Wait control registers AH, AL, BH, and BL	DRACCR*	: DRAM access control register

BROMCRH	: Area 0 burst ROM interface control register	RTCOR*	: Refresh time constant register

Note: * Not supported by the H8S/2366.

Figure 6.1 Block Diagram of Bus Controller

6.2 Input/Output Pins

Table 6.1 summarizes the pin configuration of the bus controller.

Table 6.1 Pin Configuration

Name	Symbol	I/O	Function
Address strobe	\overline{AS}	Output	Strobe signal indicating that normal space is accessed and address output on address bus is enabled.
Read	\overline{RD}	Output	Strobe signal indicating that normal space is being read.
High write	\overline{HWR}	Output	Strobe signal indicating that normal space is written to, and upper half (D15 to D8) of data bus is enabled or DRAM space write enable signal.
Low write	\overline{LWR}	Output	Strobe signal indicating that normal space is written to, and lower half (D7 to D0) of data bus is enabled.
Chip select 0	$\overline{CS0}$	Output	Strobe signal indicating that area 0 is selected.
Chip select 1	$\overline{CS1}$	Output	Strobe signal indicating that area 1 is selected
Chip select 2/row address strobe 2*	$\overline{CS2}/\overline{RAS2}^*$	Output	Strobe signal indicating that area 2 is selected, DRAM row address strobe signal when area 2 is DRAM space or areas 2 to 5 are set as continuous DRAM space.
Chip select 3/row address strobe 3*	$\overline{CS3}/\overline{RAS3}^*$	Output	Strobe signal indicating that area 3 is selected, DRAM row address strobe signal when area 3 is DRAM space.
Chip select 4	$\overline{CS4}$	Output	Strobe signal indicating that area 4 is selected.
Chip select 5	$\overline{CS5}$	Output	Strobe signal indicating that area 5 is selected.
Chip select 6	$\overline{CS6}$	Output	Strobe signal indicating that area 6 is selected.
Chip select 7	$\overline{CS7}$	Output	Strobe signal indicating that area 7 is selected.
Upper column address strobe*	\overline{UCAS}^*	Output	16-bit DRAM space upper column address strobe signal, 8-bit DRAM space column address strobe signal.
Lower column address strobe*	\overline{LCAS}^*	Output	16-bit DRAM space lower column address strobe signal.

Name	Symbol	I/O	Function
Output enable*	\overline{OE}^*	Output	Output enable signal for the DRAM space.
Wait	\overline{WAIT}	Input	Wait request signal when accessing external address space.
Bus request	\overline{BREQ}	Input	Request signal for release of bus to external bus master.
Bus request acknowledge	\overline{BACK}	Output	Acknowledge signal indicating that bus has been released to external bus master.
Bus request output	\overline{BREQO}	Output	External bus request signal used when internal bus master accesses external address space when external bus is released.
Data transfer acknowledge 1 (DMAC) *	$\overline{DACK1}^*$	Output	Data transfer acknowledge signal for single address transfer by DMAC channel 1.
Data transfer acknowledge 0 (DMAC) *	$\overline{DACK0}^*$	Output	Data transfer acknowledge signal for single address transfer by DMAC channel 0.

Note: * Not supported by the H8S/2366.

6.3 Register Descriptions

The bus controller has the following registers.

- Bus width control register (ABWCR)
- Access state control register (ASTCR)
- Wait control register AH (WTCRAH)
- Wait control register AL (WTCRAL)
- Wait control register BH (WTCRBH)
- Wait control register BL (WTCRBL)
- Read strobe timing control register (RDNCR)
- \overline{CS} assertion period control register H (CSACRH)
- \overline{CS} assertion period control register L (CSACRL)
- Area 0 burst ROM interface control register (BROMCRH)
- Area 1 burst ROM interface control register (BROMCRL)
- Bus control register (BCR)
- DRAM control register (DRAMCR)*
- DRAM access control register (DRACCR)*
- Refresh control register (REFCR)*
- Refresh timer counter (RTCNT)*
- Refresh time constant register (RTCOR)*

Note: * Not supported by the H8S/2366.

6.3.1 Bus Width Control Register (ABWCR)

ABWCR designates each area in the external address space as either 8-bit access space or 16-bit access space.

Bit	Bit Name	Initial Value*	R/W	Description
7	ABW7	1/0	R/W	Area 7 to 0 Bus Width Control
6	ABW6	1/0	R/W	These bits select whether the corresponding area is to be designated as 8-bit access space or 16-bit access space.
5	ABW5	1/0	R/W	
4	ABW4	1/0	R/W	
3	ABW3	1/0	R/W	
2	ABW2	1/0	R/W	0: Area n is designated as 16-bit access space
1	ABW1	1/0	R/W	1: Area n is designated as 8-bit access space
0	ABW0	1/0	R/W	(n = 7 to 0)

Note: * In modes 2 and 4, ABWCR is initialized to 1. In modes 1 and 7, ABWCR is initialized to 0.

6.3.2 Access State Control Register (ASTCR)

ASTCR designates each area in the external address space as either 2-state access space or 3-state access space.

Bit	Bit Name	Initial Value	R/W	Description
7	AST7	1	R/W	Area 7 to 0 Access State Control
6	AST6	1	R/W	These bits select whether the corresponding area is to be designated as 2-state access space or 3-state access space. Wait state insertion is enabled or disabled at the same time.
5	AST5	1	R/W	
4	AST4	1	R/W	
3	AST3	1	R/W	
2	AST2	1	R/W	0: Area n is designated as 2-state access space Wait state insertion in area n access is disabled
1	AST1	1	R/W	
0	AST0	1	R/W	1: Area n is designated as 3-state access space Wait state insertion in area n access is enabled
				(n = 7 to 0)

6.3.3 Wait Control Registers AH, AL, BH, and BL (WTCRAH, WTCRAL, WTCRBH, and WTCRBL)

WTCRA and WTCRB select the number of program wait states for each area in the external address space.

- WTCRAH

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
14	W72	1	R/W	Area 7 Wait Control 2 to 0
13	W71	1	R/W	These bits select the number of program wait states when accessing area 7 while AST7 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
12	W70	1	R/W	
11	—	0	R	Reserved This bit is always read as 0 and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
10	W62	1	R/W	Area 6 Wait Control 2 to 0
9	W61	1	R/W	These bits select the number of program wait states when accessing area 6 while AST6 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
8	W60	1	R/W	

- WTARAL

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
6	W52	1	R/W	Area 5 Wait Control 2 to 0
5	W51	1	R/W	These bits select the number of program wait states when accessing area 5 while AST5 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
4	W50	1	R/W	

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
2	W42	1	R/W	Area 4 Wait Control 2 to 0
1	W41	1	R/W	These bits select the number of program wait states when accessing area 4 while AST4 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
0	W40	1	R/W	

- WTCRBH

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
14	W32	1	R/W	Area 3 Wait Control 2 to 0
13	W31	1	R/W	These bits select the number of program wait states when accessing area 3 while AST3 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
12	W30	1	R/W	
11	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
10	W22	1	R/W	Area 2 Wait Control 2 to 0
9	W21	1	R/W	These bits select the number of program wait states when accessing area 2 while AST2 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
8	W20	1	R/W	

- WTCRBL

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
6	W12	1	R/W	Area 1 Wait Control 2 to 0
5	W11	1	R/W	These bits select the number of program wait states when accessing area 1 while AST1 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
4	W10	1	R/W	
3	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
2	W02	1	R/W	Area 0 Wait Control 2 to 0
1	W01	1	R/W	These bits select the number of program wait states when accessing area 0 while AST0 bit in ASTCR = 1. 000: Program wait not inserted 001: 1 program wait state inserted 010: 2 program wait states inserted 011: 3 program wait states inserted 100: 4 program wait states inserted 101: 5 program wait states inserted 110: 6 program wait states inserted 111: 7 program wait states inserted
0	W00	1	R/W	

6.3.4 Read Strobe Timing Control Register (RDNCR)

RDNCR selects the read strobe signal (\overline{RD}) negation timing in a basic bus interface read access.

Bit	Bit Name	Initial Value	R/W	Description
7	RDN7	0	R/W	Read Strobe Timing Control 7 to 0
6	RDN6	0	R/W	These bits set the negation timing of the read strobe in a corresponding area read access.
5	RDN5	0	R/W	
4	RDN4	0	R/W	
3	RDN3	0	R/W	As shown in figure 6.2, the read strobe for an area for which the RDNn bit is set to 1 is
2	RDN2	0	R/W	negated one half-state earlier than that for an
1	RDN1	0	R/W	area for which the RDNn bit is cleared to 0. The
0	RDN0	0	R/W	read data setup and hold time specifications are

also one half-state earlier.

0: In an area n read access, the \overline{RD} is negated at the end of the read cycle

1: In an area n read access, the \overline{RD} is negated one half-state before the end of the read cycle

(n = 7 to 0)

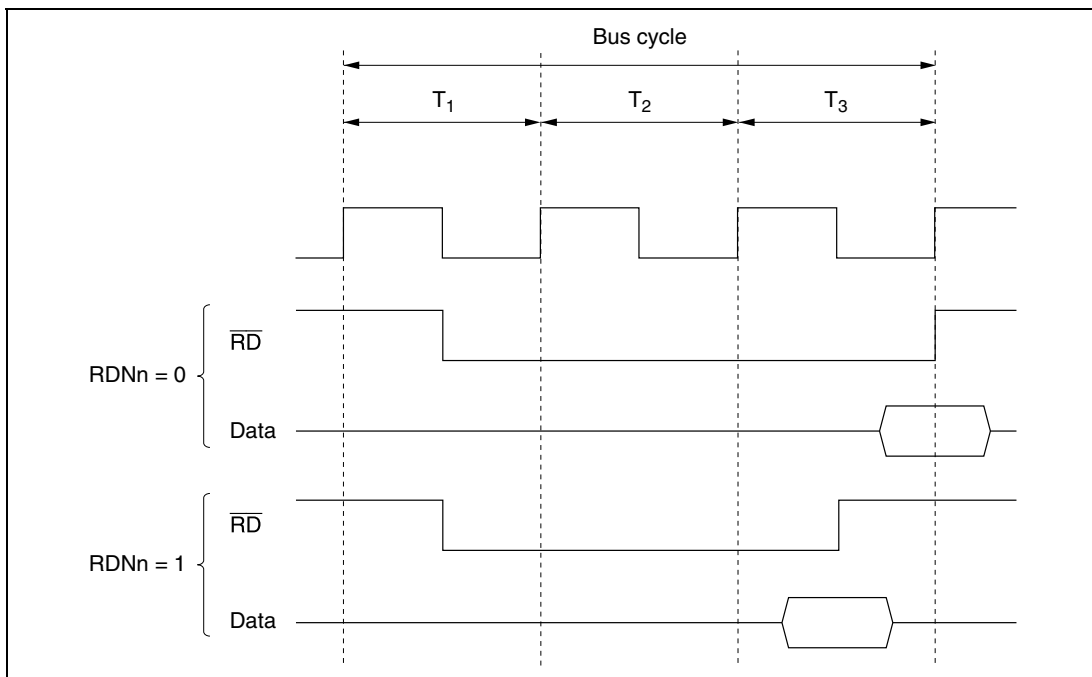

Figure 6.2 Read Strobe Negation Timing (Example of 3-State Access Space)

6.3.5 $\overline{\text{CS}}$ Assertion Period Control Registers H, L (CSACRH, CSACRL)

CSACRH and CSACRL select whether or not the assertion period of the basic bus interface chip select signals ($\overline{\text{CSn}}$) and address signals is to be extended. Extending the assertion period of the $\overline{\text{CSn}}$ and address signals allows flexible interfacing to external I/O devices.

• CSACRH

Bit	Bit Name	Initial Value	R/W	Description
7	CSXH7	0	R/W	$\overline{\text{CS}}$ and Address Signal Assertion Period
6	CSXH6	0	R/W	Control 1
5	CSXH5	0	R/W	These bits specify whether or not the T_h cycle is to be inserted (see figure 6.3). When an area for which the CSXHn bit is set to 1 is accessed, a one-state T_h cycle, in which only the $\overline{\text{CSn}}$ and address signals are asserted, is inserted before the normal access cycle.
4	CSXH4	0	R/W	
3	CSXH3	0	R/W	
2	CSXH2	0	R/W	
1	CSXH1	0	R/W	
0	CSXH0	0	R/W	
				0: In area n basic bus interface access, the $\overline{\text{CSn}}$ and address assertion period (T_h) is not extended
				1: In area n basic bus interface access, the $\overline{\text{CSn}}$ and address assertion period (T_h) is extended
				(n = 7 to 0)

• CSACRL

Bit	Bit Name	Initial Value	R/W	Description
7	CSXT7	0	R/W	$\overline{\text{CS}}$ and Address Signal Assertion Period
6	CSXT6	0	R/W	Control 2
5	CSXT5	0	R/W	These bits specify whether or not the T_l cycle shown in figure 6.3 is to be inserted. When an area for which the CSXTn bit is set to 1 is accessed, a one-state T_l cycle, in which only the $\overline{\text{CSn}}$ and address signals are asserted, is inserted before the normal access cycle.
4	CSXT4	0	R/W	
3	CSXT3	0	R/W	
2	CSXT2	0	R/W	
1	CSXT1	0	R/W	
0	CSXT0	0	R/W	
				0: In area n basic bus interface access, the $\overline{\text{CSn}}$ and address assertion period (T_l) is not extended
				1: In area n basic bus interface access, the $\overline{\text{CSn}}$ and address assertion period (T_l) is extended
				(n = 7 to 0)

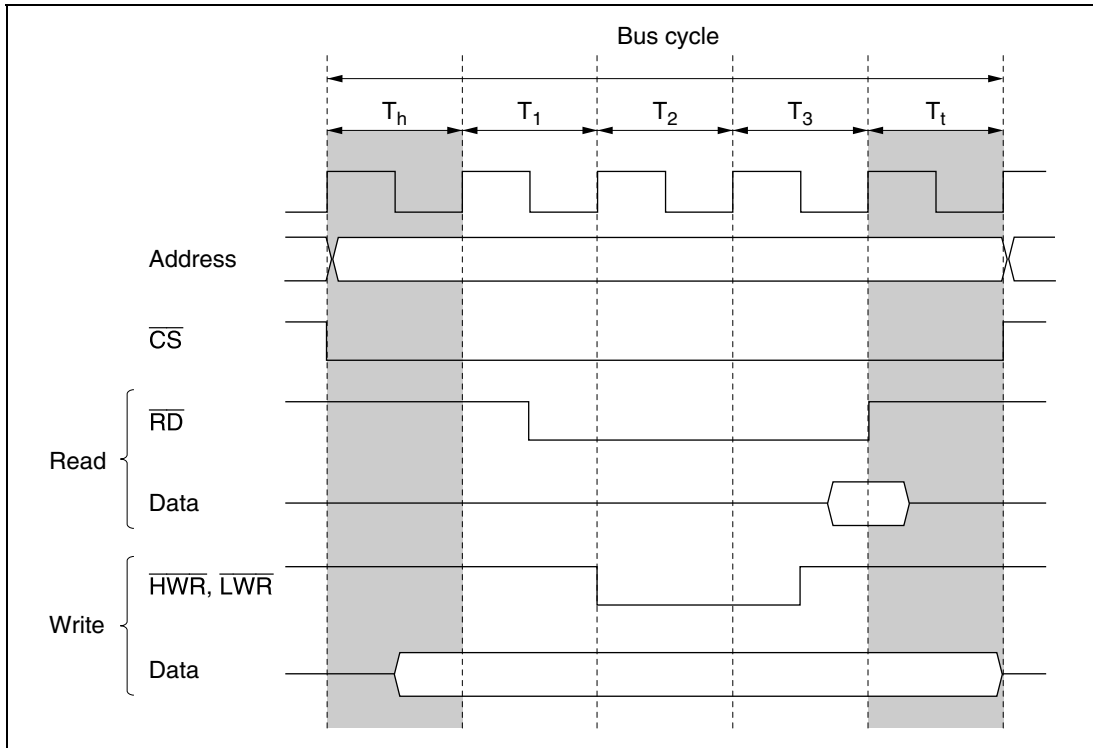

Figure 6.3 \overline{CS} and Address Assertion Period Extension (Example of 3-State Access Space and $RDNn = 0$)

6.3.6 Area 0 Burst ROM Interface Control Register (BROMCRH)

Area 1 Burst ROM Interface Control Register (BROMCRL)

BROMCRH and BROMCRL are used to make burst ROM interface settings. Area 0 and area 1 burst ROM interface settings can be made independently in BROMCRH and BROMCRL, respectively.

Bit	Bit Name	Initial Value	R/W	Description
7	BSRMn	0	R/W	Burst ROM Interface Select Selects the basic bus interface or burst ROM interface. 0: Basic bus interface space 1: Burst ROM interface space
6	BSTSn2	0	R/W	Burst Cycle Select
5	BSTSn1	0	R/W	These bits select the number of burst cycle states. 000: 1 state 001: 2 states 010: 3 states 011: 4 states 100: 5 states 101: 6 states 110: 7 states 111: 8 states
4	BSTSn0	0	R/W	
3 and 2	—	0	R/W	Reserved Though these bits can be read from or written to, the write value should always be 0.
1	BSWDn1	0	R/W	Burst Word Number Select
0	BSWDn0	0	R/W	These bits select the number of words that can be burst-accessed on the burst ROM interface. 00: Maximum 4 words 01: Maximum 8 words 10: Maximum 16 words 11: Maximum 32 words

(n = 1 or 0)

6.3.7 Bus Control Register (BCR)

BCR is used for idle cycle settings, selection of the external bus released state protocol, enabling or disabling of the write data buffer function, and enabling or disabling of WAIT pin input.

Bit	Bit Name	Initial Value	R/W	Description
15	BRLE	0	R/W	External Bus Release Enable Enables or disables external bus release. 0: External bus release disabled BRE \overline{Q} , BACK, and BRE \overline{Q} pins can be used as I/O ports 1: External bus release enabled
14	BREQOE	0	R/W	BRE \overline{Q} Pin Enable Controls outputting the bus request signal (BRE \overline{Q}) to the external bus master in the external bus released state, when an internal bus master performs an external address space access, or when a refresh request is generated. 0: BRE \overline{Q} output disabled BRE \overline{Q} pin can be used as I/O port 1: BRE \overline{Q} output enabled
13	—	0	R/W	Reserved Though this bit can be read from or written to, the write value should always be 0.
12	IDLC	1	R/W	Idle Cycle State Number Select Specifies the number of states in the idle cycle set by ICIS2, ICIS1, and ICIS0. 0: Idle cycle comprises 1 state 1: Idle cycle comprises 2 states
11	ICIS1	1	R/W	Idle Cycle Insert 1 When consecutive external read cycles are performed in different areas, an idle cycle can be inserted between the bus cycles. 0: Idle cycle not inserted 1: Idle cycle inserted

Bit	Bit Name	Initial Value	R/W	Description
10	ICIS0	1	R/W	<p>Idle Cycle Insert 0</p> <p>When an external read cycle and external write cycle are performed consecutively, an idle cycle can be inserted between the bus cycles.</p> <p>0: Idle cycle not inserted 1: Idle cycle inserted</p>
9	WDBE	0	R/W	<p>Write Data Buffer Enable</p> <p>The write data buffer function can be used for an external write cycle or DMAC single address transfer cycle.</p> <p>0: Write data buffer function not used 1: Write data buffer function used</p>
8	WAITE	0	R/W	<p>$\overline{\text{WAIT}}$ Pin Enable</p> <p>Selects enabling or disabling of wait input by the $\overline{\text{WAIT}}$ pin.</p> <p>0: Wait input by $\overline{\text{WAIT}}$ pin disabled $\overline{\text{WAIT}}$ pin can be used as I/O port 1: Wait input by $\overline{\text{WAIT}}$ pin enabled</p>
7 to 3	—	0	R/W	<p>Reserved</p> <p>Though these bits can be read from or written to, the write value should always be 0.</p>
2	ICIS2	0	R/W	<p>Idle Cycle Insert 2</p> <p>When an external write cycle and external read cycle are performed consecutively, an idle cycle can be inserted between the bus cycles.</p> <p>0: Idle cycle not inserted 1: Idle cycle inserted</p>
1 and 0	—	0	R/W	<p>Reserved</p> <p>Though these bits can be read from or written to, the write value should always be 0.</p>

6.3.8 DRAM Control Register (DRAMCR)

DRAMCR is used to make DRAM/synchronous DRAM interface settings.

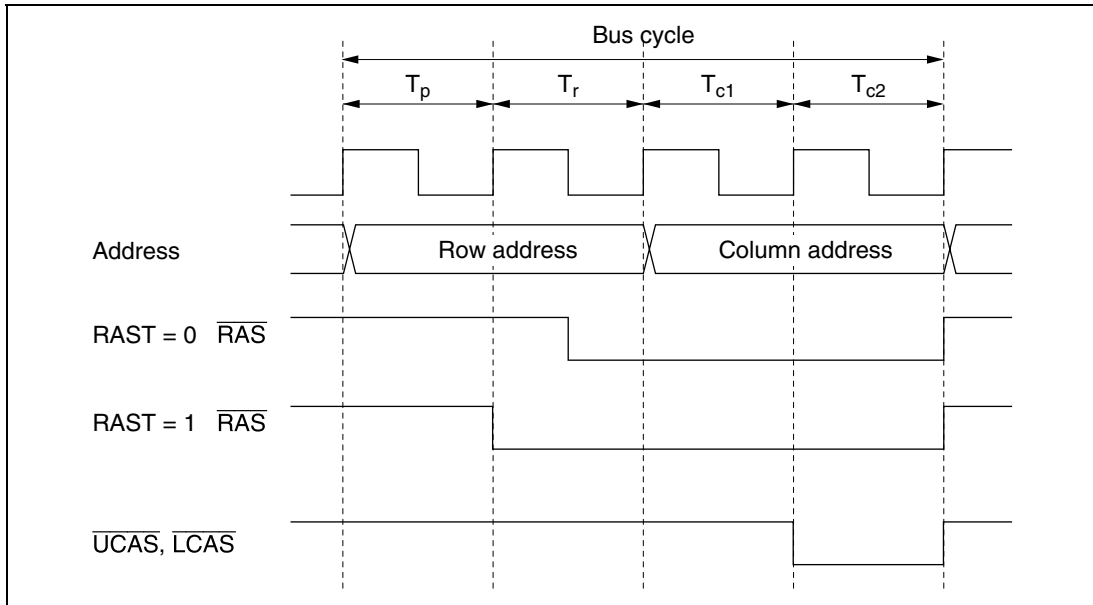

Note: The DRAM interface is not supported by the H8S/2366.

Bit	Bit Name	Initial Value	R/W	Description
15	OEE	0	R/W	<p>\overline{OE} Output Enable</p> <p>The OE signal used when EDO page mode DRAM is connected can be output from the (\overline{OE}) pin. The \overline{OE} signal is common to all areas designated as DRAM space.</p> <p>0: \overline{OE} signal output disabled (\overline{OE}) pin can be used as I/O port</p> <p>1: \overline{OE} signal output enabled</p>
14	RAST	0	R/W	<p>\overline{RAS} Assertion Timing Select</p> <p>Selects whether, in DRAM access, the \overline{RAS} signal is asserted from the start of the T_r cycle (rising edge of ϕ) or from the falling edge of ϕ.</p> <p>Figure 6.4 shows the relationship between the RAST bit setting and the \overline{RAS} assertion timing.</p> <p>The setting of this bit applies to all areas designated as DRAM space.</p> <p>0: \overline{RAS} is asserted from ϕ falling edge in T_r cycle</p> <p>1: \overline{RAS} is asserted from start of T_r cycle</p>
13	—	0	R/W	<p>Reserved</p> <p>Though this bit can be read from or written to, the write value should always be 0.</p>
12	CAST	0	R/W	<p>Column Address Output Cycle Number Select</p> <p>Selects whether the column address output cycle in DRAM access comprises 3 states or 2 states. The setting of this bit applies to all areas designated as DRAM space.</p> <p>0: 2-state column address output cycle</p> <p>1: 3-state column address output cycle</p>
11	—	0	R/W	<p>Reserved</p> <p>Though this bit can be read from or written to, the write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
10	RMTS2	0	R/W	DRAM Space Select
9	RMTS1	0	R/W	These bits designate DRAM space for areas 2 to 5. When continuous DRAM space is set, it is possible to connect large-capacity DRAM exceeding 2 Mbytes per area. In this case, the $\overline{\text{RAS}}$ signal is output from the $\overline{\text{CS2}}$ pin. 000: Normal space 001: Normal space in areas 3 to 5 DRAM space in area 2 010: Normal space in areas 4 and 5 DRAM space in areas 2 and 3 011: Reserved (setting prohibited) 100: Reserved (setting prohibited) 101: Reserved (setting prohibited) 110: Reserved (setting prohibited) 111: Continuous DRAM space in areas 2 to 5
8	RMTS0	0	R/W	
7	BE	0	R/W	Burst Access Enable Selects enabling or disabling of burst access to areas designated as DRAM space. DRAM space burst access is performed in fast page mode. When using EDO page mode DRAM, the $\overline{\text{OE}}$ signal must be connected. 0: Full access 1: Access in fast page mode

Bit	Bit Name	Initial Value	R/W	Description
6	RCDM	0	R/W	<p>$\overline{\text{RAS}}$ Down Mode</p> <p>When access to DRAM space is interrupted by an access to normal space, an access to an internal I/O register, etc., this bit selects whether the $\overline{\text{RAS}}$ signal is held low while waiting for the next DRAM access ($\overline{\text{RAS}}$ down mode), or is driven high again ($\overline{\text{RAS}}$ up mode). The setting of this bit is valid only when the BE bit is set to 1.</p> <p>If this bit is cleared to 0 when set to 1 in the $\overline{\text{RAS}}$ down state, the $\overline{\text{RAS}}$ down state is cleared at that point, and $\overline{\text{RAS}}$ goes high.</p> <p>0: $\overline{\text{RAS}}$ up mode selected for DRAM space access</p> <p>1: $\overline{\text{RAS}}$ down mode selected for DRAM space access</p>
5	DDS	0	R/W	<p>DMAC Single Address Transfer Option</p> <p>Selects whether full access is always performed or burst access is enabled when DMAC single address transfer is performed on the DRAM</p> <p>When the BE bit is cleared to 0 in DRAMCR, disabling DRAM burst access, DMAC single address transfer is performed in full access mode regardless of the setting of this bit.</p> <p>This bit has no effect on other bus master external accesses or DMAC dual address transfers.</p> <p>0: Full access is always executed</p> <p>1: Burst access is enabled</p>
4 and 3	—	0	R/W	<p>Reserved</p> <p>Though these bits can be read from or written to, the write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
2	MXC2	0	R/W	Address Multiplex Select
1	MXC1	0	R/W	<p>These bits select the size of the shift toward the lower half of the row address in row address/column address multiplexing. In burst operation on the DRAM interface, these bits also select the row address bits to be used for comparison.</p> <p>For details, refer to section 6.6.2, Address Multiplexing.</p> <p>000: 8-bit shift</p> <ul style="list-style-type: none"> When 8-bit access space is designated: Row address bits A23 to A8 used for comparison When 16-bit access space is designated: Row address bits A23 to A9 used for comparison <p>001: 9-bit shift</p> <ul style="list-style-type: none"> When 8-bit access space is designated: Row address bits A23 to A9 used for comparison When 16-bit access space is designated: Row address bits A23 to A10 used for comparison <p>010: 10-bit shift</p> <ul style="list-style-type: none"> When 8-bit access space is designated: Row address bits A23 to A10 used for comparison When 16-bit access space is designated: Row address bits A23 to A11 used for comparison <p>011: 11-bit shift</p> <ul style="list-style-type: none"> When 8-bit access space is designated: Row address bits A23 to A11 used for comparison When 16-bit access space is designated: Row address bits A23 to A12 used for comparison <p>1xx: Setting prohibited</p>
0	MXC0	0	R/W	

**Figure 6.4 $\overline{\text{RAS}}$ Signal Assertion Timing
(2-State Column Address Output Cycle, Full Access)**

6.3.9 DRAM Access Control Register (DRACCR)

DRACCR is used to set the DRAM interface bus specifications.

Note: The DRAM interface is not supported by the H8S/2366.

Bit	Bit Name	Initial Value	R/W	Description
7	DRMI	0	R/W	Idle Cycle Insertion An idle cycle can be inserted after a DRAM access cycle when a continuous normal space access cycle follows a DRAM access cycle. Idle cycle insertion conditions, setting of number of states, etc., comply with settings of bits ICIS2, ICIS1, ICIS0, and IDLC in BCR register 0: Idle cycle not inserted 1: Idle cycle inserted
6	—	0	R/W	Reserved Though this bit can be read from or written to, the write value should always be 0.
5	TPC1	0	R/W	Precharge State Control These bits select the number of states in the RAS precharge cycle in normal access and refreshing. 00: 1-state RAS precharge cycle 01: 2-state RAS precharge cycle 10: 3-state RAS precharge cycle 11: 4-state RAS precharge cycle
4	TPC0	0	R/W	
3 and 2	—	0	R/W	Reserved Though these bits can be read from or written to, the write value should always be 0.
1	RCD1	0	R/W	RAS-CAS Wait Control These bits select a wait cycle to be inserted between the $\overline{\text{RAS}}$ assert cycle and $\overline{\text{CAS}}$ assert cycle. A 1- to 4-state wait cycle can be inserted. 00: Wait cycle not inserted 01: 1-state wait cycle inserted 10: 2-state wait cycle inserted 11: 3-state wait cycle inserted
0	RCD0	0	R/W	

6.3.10 Refresh Control Register (REFCR)

REFCR specifies DRAM interface refresh control.

Note: The DRAM interface is not supported by the H8S/2366.

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	0	R/(W)*	Compare Match Flag Status flag that indicates a match between the values of RTCNT and RTCOR. [Clearing conditions] <ul style="list-style-type: none">When 0 is written to CMF after reading CMF = 1 while the RFSHE bit is cleared to 0When CBR refreshing is executed while the RFSHE bit is set to 1 [Setting condition] When RTCOR = RTCNT
14	CMIE	0	R/W	Compare Match Interrupt Enable Enables or disables interrupt requests (CMI) by the CMF flag when the CMF flag is set to 1. This bit is valid when refresh control is not performed. When the refresh control is performed, this bit is always cleared to 0 and cannot be modified. 0: Interrupt request by CMF flag disabled 1: Interrupt request by CMF flag enabled
13	RCW1	0	R/W	CAS-RAS Wait Control These bits select the number of wait cycles to be inserted between the CAS assert cycle and RAS assert cycle in a DRAM refresh cycle. 00: Wait state not inserted 01: 1 wait state inserted 10: 2 wait states inserted 11: 3 wait states inserted
12	RCW0	0	R/W	
11	—	0	R/W	Reserved Though this bit can be read from or written to, the write value should always be 0.

Note: * Only 0 can be written, to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
10	RTCK2	0	R/W	Refresh Counter Clock Select
9	RTCK1	0	R/W	These bits select the clock to be used to increment the refresh counter. When the input clock is selected with bits RTCK2 to RTCK0, the refresh counter begins counting up. 000: Count operation halted 001: Count on $\phi/2$ 010: Count on $\phi/8$ 011: Count on $\phi/32$ 100: Count on $\phi/128$ 101: Count on $\phi/512$ 110: Count on $\phi/2048$ 111: Count on $\phi/4096$
8	RTCK0	0	R/W	
7	RFSHE	0	R/W	Refresh Control Refresh control can be performed. When refresh control is not performed, the refresh timer can be used as an interval timer. 0: Refresh control is not performed 1: Refresh control is performed
6	CBRM	0	R/W	CBR Refresh Control Mode Selects CBR refreshing performed in parallel with other external accesses, or execution of CBR refreshing alone. 0: External access during CAS-before-RAS refreshing is enabled 1: External access during CAS-before-RAS refreshing is disabled
5	RLW1	0	R/W	Refresh Cycle Wait Control These bits select the number of wait states to be inserted in a DRAM interface CAS-before-RAS refresh cycle. This setting applies to all areas designated as DRAM space. 00: No wait state inserted 01: 1 wait state inserted 10: 2 wait states inserted 11: 3 wait states inserted
4	RLW0	0	R/W	

Bit	Bit Name	Initial Value	R/W	Description
3	SLFRF	0	R/W	<p>Self-Refresh Enable</p> <p>If this bit is set to 1, DRAM self-refresh mode is selected when a transition is made to the software standby state. This bit is valid when the RFSHE bit is set to 1, enabling refresh operations. It is cleared after recovery from software standby mode.</p> <p>0: Self-refreshing is disabled</p> <p>1: Self-refreshing is enabled</p>
2	TPCS2	0	R/W	Self-Refresh Precharge Cycle Control
1	TPCS1	0	R/W	<p>These bits select the number of states in the precharge cycle immediately after self-refreshing.</p> <p>The number of states in the precharge cycle immediately after self-refreshing are added to the number of states set by bits TPC1 and TPC0 in DRACCR.</p> <p>000: [TPC set value] states</p> <p>001: [TPC set value + 1] states</p> <p>010: [TPC set value + 2] states</p> <p>011: [TPC set value + 3] states</p> <p>100: [TPC set value + 4] states</p> <p>101: [TPC set value + 5] states</p> <p>110: [TPC set value + 6] states</p> <p>111: [TPC set value + 7] states</p>
0	TPCS0	0	R/W	

6.3.11 Refresh Timer Counter (RTCNT)

RTCNT is an 8-bit readable/writable up-counter. RTCNT counts up using the internal clock selected by bits RTCK2 to RTCK0 in REFCR.

When RTCNT matches RTCOR (compare match), the CMF flag in REFCR is set to 1 and RTCNT is cleared to H'00. If the RFSHE bit in REFCR is set to 1 at this time, a refresh cycle is started. If the RFSHE bit is cleared to 0 and the CMIE bit in REFCR is set to 1, a compare match interrupt (CMI) is generated.

RTCNT is initialized to H'00 by a reset and in hardware standby mode. It is not initialized in software standby mode.

Note: Not supported by the H8S/2366.

6.3.12 Refresh Time Constant Register (RTCOR)

RTCOR is an 8-bit readable/writable register that sets the period for compare match operations with RTCNT.

The values of RTCOR and RTCNT are constantly compared, and if they match, the CMF flag in REFCR is set to 1 and RTCNT is cleared to H'00.

RTCOR is initialized to H'FF by a reset and in hardware standby mode. It is not initialized in software standby mode.

Note: Not supported by the H8S/2366.

6.4 Operation

6.4.1 Area Division

The bus controller divides the 16-Mbyte address space into eight areas, 0 to 7, in 2-Mbyte units, and performs bus control for external address space in area units. Chip select signals ($\overline{CS0}$ to $\overline{CS7}$) can be output for each area. Figure 6.5 shows an outline of the memory map.

H'000000	Area 0 (2 Mbytes)
H'1FFFFFF H'200000	Area 1 (2 Mbytes)
H'3FFFFFF H'400000	Area 2 (2 Mbytes)
H'5FFFFFF H'600000	Area 3 (2 Mbytes)
H'7FFFFFF H'800000	Area 4 (2 Mbytes)
H'9FFFFFF H'A00000	Area 5 (2 Mbytes)
H'BFFFFFF H'C00000	Area 6 (2 Mbytes)
H'DFFFFFF H'E00000	Area 7 (2 Mbytes)
--- H'FFFFFF	

Figure 6.5 Area Divisions

6.4.2 Bus Specifications

The external space bus specifications consist of five elements: bus width, number of access states, number of program wait states, read strobe timing, and chip select (\overline{CS}) assertion period extension states. The bus width and number of access states for on-chip memory and internal I/O registers are fixed, and are not affected by the bus controller.

Bus Width: A bus width of 8 or 16 bits can be selected with ABWCR. An area for which an 8-bit bus is selected functions as an 8-bit access space, and an area for which a 16-bit bus is selected functions as a 16-bit access space. If all areas are designated as 8-bit access space, 8-bit bus mode is set; if any area is designated as 16-bit access space, 16-bit bus mode is set.

Number of Access States: Two or three access states can be selected with ASTCR. An area for which 2-state access is selected functions as a 2-state access space, and an area for which 3-state access is selected functions as a 3-state access space. With the DRAM interface* and burst ROM interface, the number of access states may be determined without regard to the setting of ASTCR.

When 2-state access space is designated, wait insertion is disabled. When 3-state access space is designated, it is possible to insert program waits by means of the WTCRA and WTCRB, and external waits by means of the WAIT pin.

Note: * The DRAM interface is not supported by the H8S/2366.

Number of Program Wait States: When 3-state access space is designated by ASTCR, the number of program wait states to be inserted automatically is selected with WTCRA and WTCRB. From 0 to 7 program wait states can be selected. Table 6.2 shows the bus specifications (bus width, and number of access states and program wait states) for each basic bus interface area.

Table 6.2 Bus Specifications for Each Area (Basic Bus Interface)

ABWCR	ASTCR	WTCRA, WTCRB			Bus Specifications (Basic Bus Interface)		
ABWn	ASTn	Wn2	Wn1	Wn0	Bus Width	Access States	Program Wait States
0	0	—	—	—	16	2	0
	1	0	0	0		3	0
				1			1
			1	0			2
				1			3
		1	0	0			4
				1			5
			1	0			6

			1	0			2
				1			3
		1	0	0			4
				1			5
			1	0			6
				1			7

(n = 0 to 7)

Read Strobe Timing: RDNCR can be used to select either of two negation timings (at the end of the read cycle or one half-state before the end of the read cycle) for the read strobe ($\overline{\text{RD}}$) used in the basic bus interface space.

Chip Select ($\overline{\text{CS}}$) Assertion Period Extension States: Some external I/O devices require a setup time and hold time between address and $\overline{\text{CS}}$ signals and strobe signals such as $\overline{\text{RD}}$, $\overline{\text{HWR}}$, and $\overline{\text{LWR}}$. CSACR can be used to insert states in which only the $\overline{\text{CS}}$, $\overline{\text{AS}}$, and address signals are asserted before and after a basic bus space access cycle.

6.4.3 Memory Interfaces

The memory interfaces in this LSI comprise a basic bus interface that allows direct connection of ROM, SRAM, and so on a synchronous DRAM interface* that allows direct connection of synchronous DRAM; and a burst ROM interface that allows direct connection of burst ROM. The interface can be selected independently for each area.

An area for which the basic bus interface is designated functions as normal space, an area for which the DRAM interface is designated functions as DRAM space*, and an area for which the burst ROM interface is designated functions as burst ROM space.

The initial state of each area is basic bus interface, 3-state access space. The initial bus width is selected according to the operating mode.

Note: * The DRAM interface is not supported by the H8S/2366.

Area 0: Area 0 includes on-chip ROM in expanded mode with on-chip ROM enabled and the space excluding on-chip ROM is external space, and in expanded mode with on-chip ROM disabled, all of area 0 is external space.

When area 0 external space is accessed, the $\overline{CS0}$ signal can be output.

Either basic bus interface or burst ROM interface can be selected for area 0.

Area 1: In externally expanded mode, all of area 1 is external space.

When area 1 external space is accessed, the $\overline{CS1}$ signal can be output.

Either basic bus interface or burst ROM interface can be selected for area 1.

Areas 2 to 5: In externally expanded mode, areas 2 to 5 are all external space.

When area 2 to 5 external space is accessed, signals $\overline{CS2}$ to $\overline{CS5}$ can be output.

Basic bus interface, or DRAM interface can be selected for areas 2 to 5. With the DRAM interface, signals $\overline{CS2}$ and $\overline{CS3}$ are used as \overline{RAS} signals.

If areas 2 to 5 are designated as continuous DRAM space, large-capacity (e.g. 64-Mbit) DRAM can be connected. In this case, the $\overline{CS2}$ signal is used as the \overline{RAS} signal for the continuous DRAM space.

Area 6: In externally expanded mode, all of area 6 is external space.

When area 6 external space is accessed, the $\overline{CS6}$ signal can be output.

Only the basic bus interface can be used for area 6.

Area 7: Area 7 includes the on-chip RAM and internal I/O registers. In externally expanded mode, the space excluding the on-chip RAM and internal I/O registers is external space. The on-chip RAM is enabled when the RAME bit is set to 1 in the system control register (SYSCR); when the RAME bit is cleared to 0, the on-chip RAM is disabled and the corresponding addresses are in external space.

When area 7 external space is accessed, the $\overline{\text{CS7}}$ signal can be output.

Only the basic bus interface can be used for the area 7 memory interface.

6.4.4 Chip Select Signals

This LSI can output chip select signals ($\overline{\text{CS0}}$ to $\overline{\text{CS7}}$) for areas 0 to 7. The signal outputs low when the corresponding external space area is accessed. Figure 6.6 shows an example of $\overline{\text{CS0}}$ to $\overline{\text{CS7}}$ signals output timing.

Enabling or disabling of $\overline{\text{CS0}}$ to $\overline{\text{CS7}}$ signals output is set by the data direction register (DDR) bit for the port corresponding to the $\overline{\text{CS0}}$ to $\overline{\text{CS7}}$ pins.

In expanded mode with on-chip ROM disabled, the $\overline{\text{CS0}}$ pin is placed in the output state after a reset. Pins $\overline{\text{CS1}}$ to $\overline{\text{CS7}}$ are placed in the input state after a reset and so the corresponding DDR bits should be set to 1 when outputting signals $\overline{\text{CS1}}$ to $\overline{\text{CS7}}$.

In expanded mode with on-chip ROM enabled, pins $\overline{\text{CS0}}$ to $\overline{\text{CS7}}$ are all placed in the input state after a reset and so the corresponding DDR bits should be set to 1 when outputting signals $\overline{\text{CS0}}$ to $\overline{\text{CS7}}$.

When areas 2 to 5 are designated as DRAM space, outputs $\overline{\text{CS2}}$ is used as $\overline{\text{RAS}}$ signals.

Note: The DRAM interface is not supported by the H8S/2366.

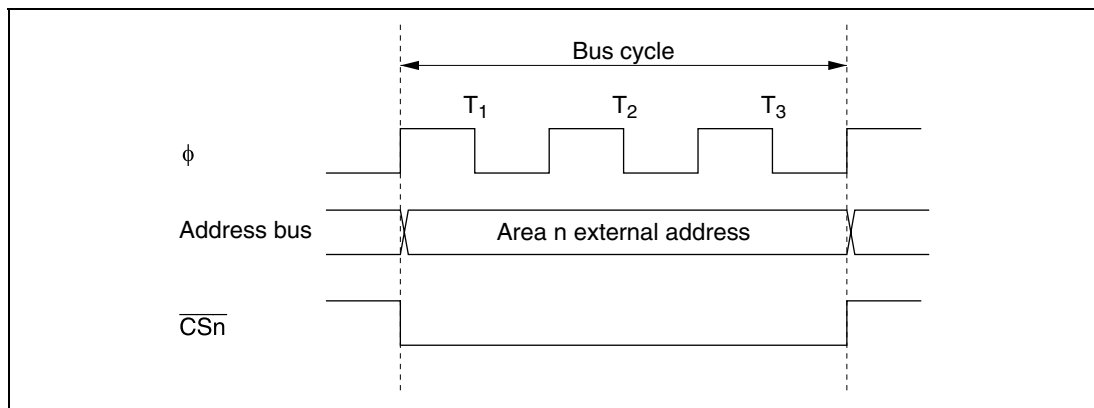

Figure 6.6 $\overline{\text{CSn}}$ Signal Output Timing (n = 0 to 7)

6.5 Basic Bus Interface

The basic bus interface enables direct connection of ROM, SRAM, and so on.

6.5.1 Data Size and Data Alignment

Data sizes for the CPU and other internal bus masters are byte, word, and longword. The bus controller has a data alignment function, and when accessing external space, controls whether the upper data bus (D15 to D8) or lower data bus (D7 to D0) is used according to the bus specifications for the area being accessed (8-bit access space or 16-bit access space) and the data size.

8-Bit Access Space: Figure 6.7 illustrates data alignment control for the 8-bit access space. With the 8-bit access space, the upper data bus (D15 to D8) is always used for accesses. The amount of data that can be accessed at one time is one byte: a word access is performed as two byte accesses, and a longword access, as four byte accesses.

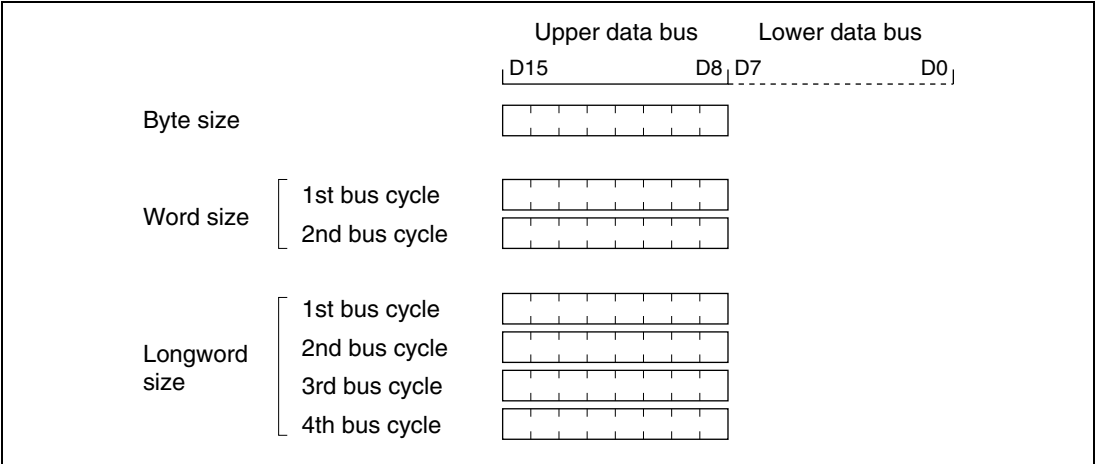

Figure 6.7 Access Sizes and Data Alignment Control (8-Bit Access Space)

16-Bit Access Space: Figure 6.8 illustrates data alignment control for the 16-bit access space. With the 16-bit access space, the upper data bus (D15 to D8) and lower data bus (D7 to D0) are used for accesses. The amount of data that can be accessed at one time is one byte or one word, and a longword access is executed as two word accesses.

In byte access, whether the upper or lower data bus is used is determined by whether the address is even or odd. The upper data bus is used for an even address, and the lower data bus for an odd address.

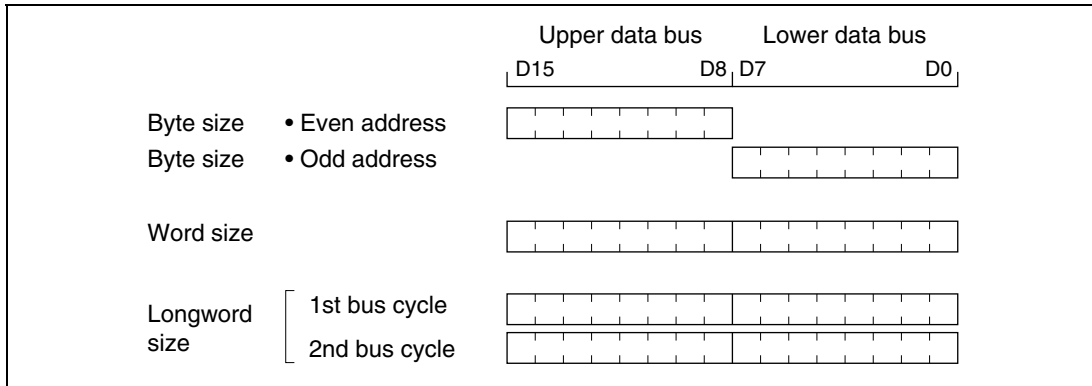

Figure 6.8 Access Sizes and Data Alignment Control (16-bit Access Space)

6.5.2 Valid Strobes

Table 6.3 shows the data buses used and valid strobes for the access spaces.

In a read, the \overline{RD} signal is valid for both the upper and the lower half of the data bus. In a write, the \overline{HWR} signal is valid for the upper half of the data bus, and the \overline{LWR} signal for the lower half.

Table 6.3 Data Buses Used and Valid Strobes

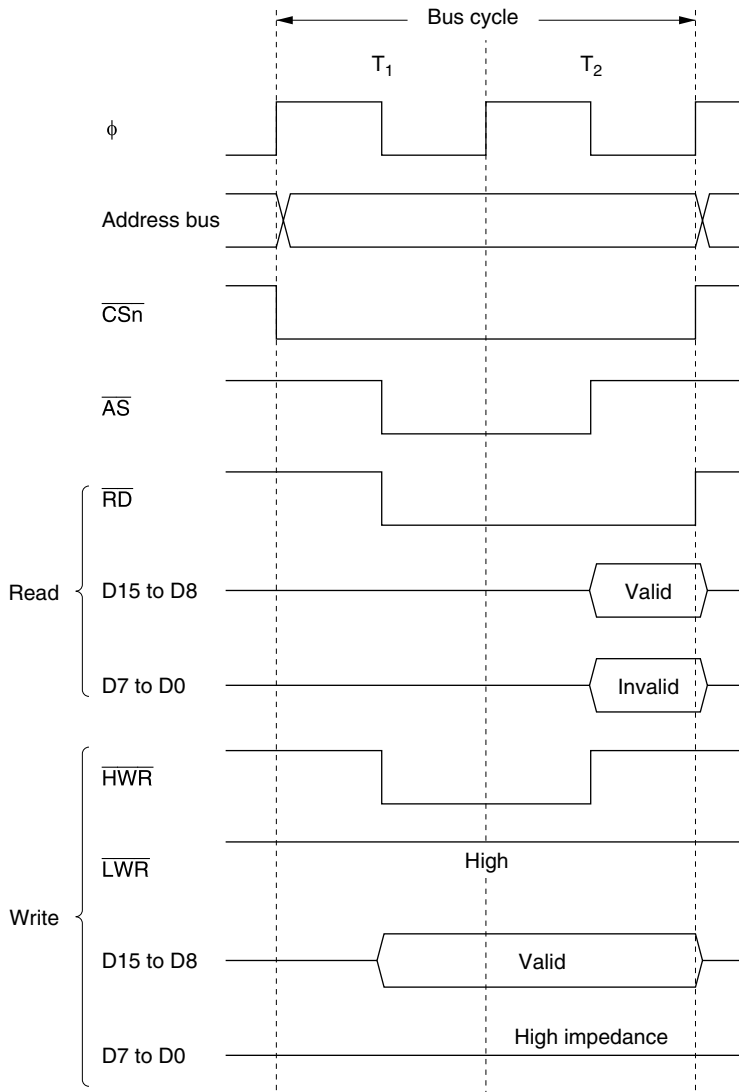

Area	Access Size	Read/Write	Address	Valid Strobe	Upper Data Bus (D15 to D8)	Lower Data Bus (D7 to D0)
8-bit access space	Byte	Read	—	\overline{RD}	Valid	Invalid
		Write	—	\overline{HWR}		Hi-Z
16-bit access space	Byte	Read	Even	\overline{RD}	Valid	Invalid
			Odd		Invalid	Valid
		Write	Even	\overline{HWR}	Valid	Hi-Z
			Odd	\overline{LWR}	Hi-Z	Valid
	Word	Read	—	\overline{RD}	Valid	Valid
		Write	—	$\overline{HWR}, \overline{LWR}$	Valid	Valid

Notes: Hi-Z: High-impedance state

Invalid: Input state; input value is ignored.

6.5.3 Basic Timing

8-Bit, 2-State Access Space: Figure 6.9 shows the bus timing for an 8-bit, 2-state access space. When an 8-bit access space is accessed, the upper half (D15 to D8) of the data bus is used. The $\overline{\text{LWR}}$ pin is always fixed high. Wait states can be inserted.

- Notes: 1. $n = 0$ to 7
2. When $\text{RDNn} = 0$

Figure 6.9 Bus Timing for 8-Bit, 2-State Access Space

8-Bit, 3-State Access Space: Figure 6.10 shows the bus timing for an 8-bit, 3-state access space. When an 8-bit access space is accessed, the upper half (D15 to D8) of the data bus is used. The $\overline{\text{LWR}}$ pin is always fixed high. Wait states can be inserted.

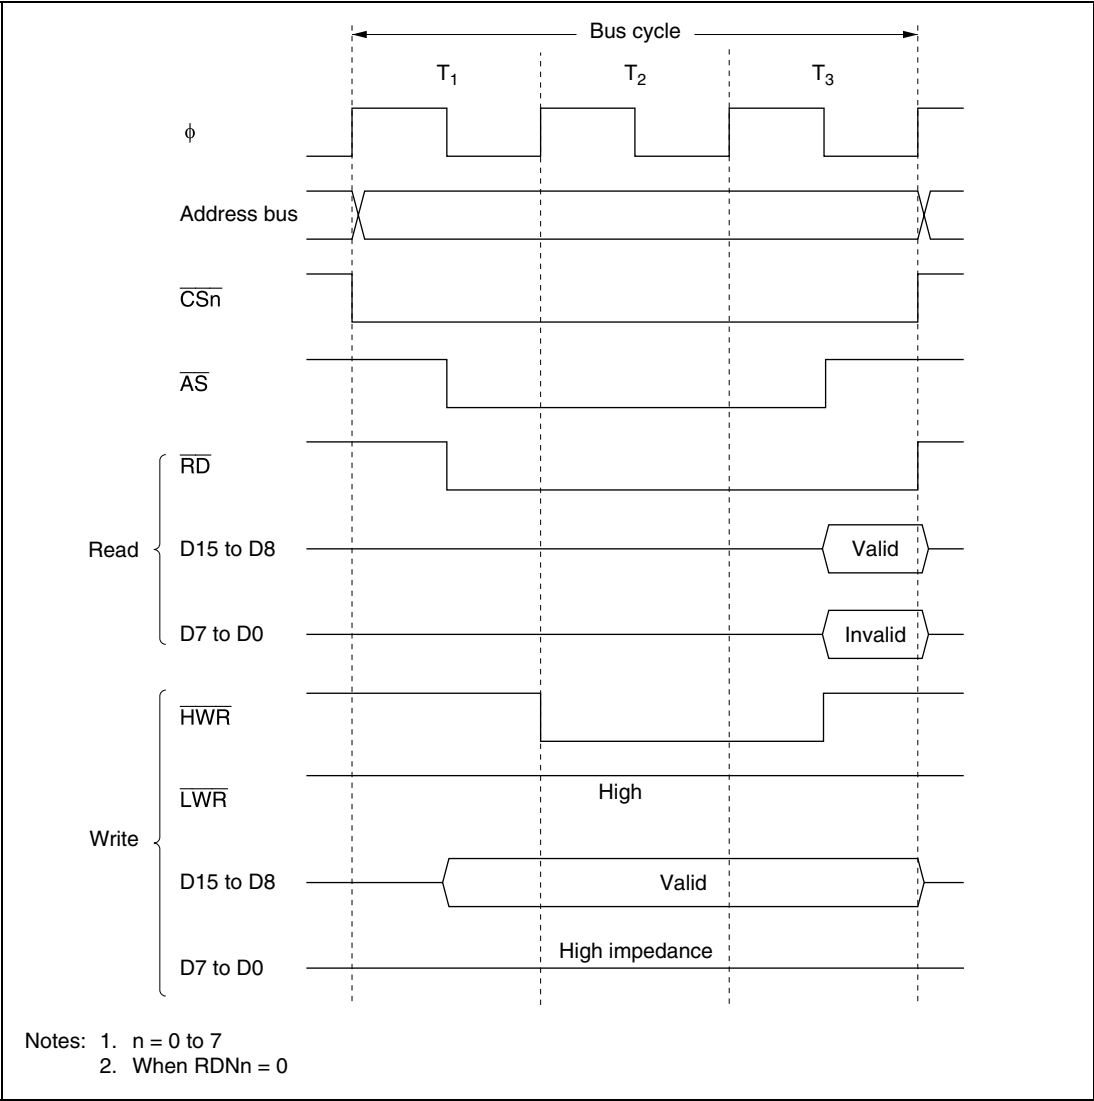

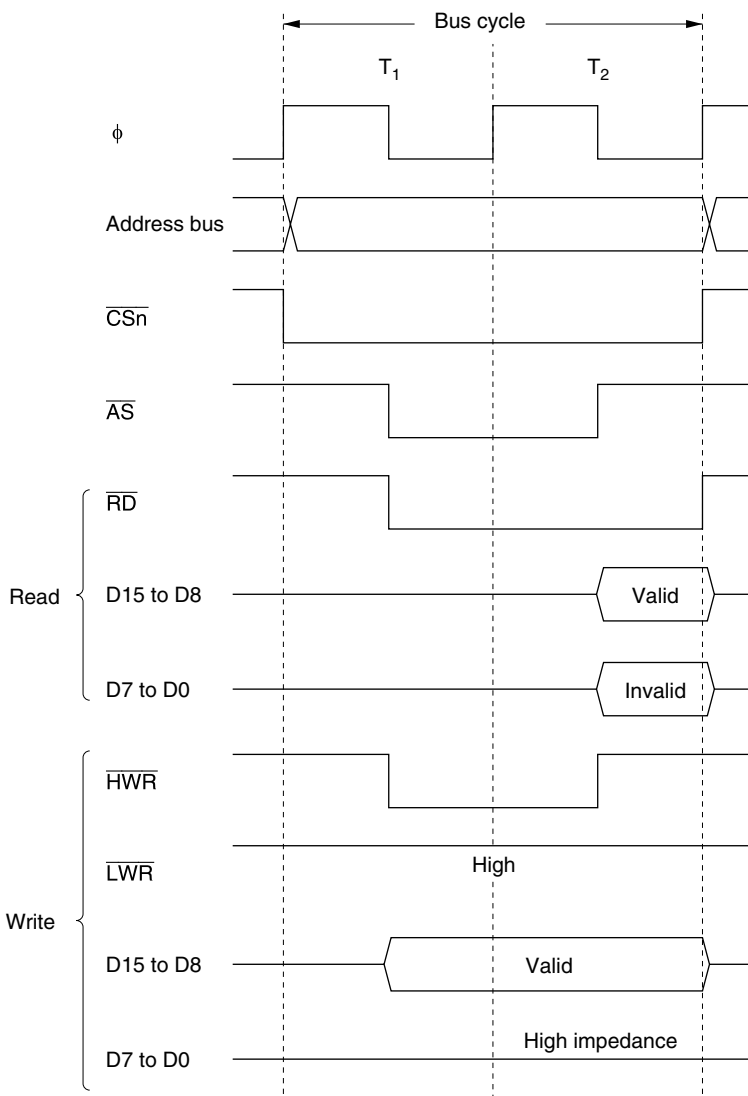

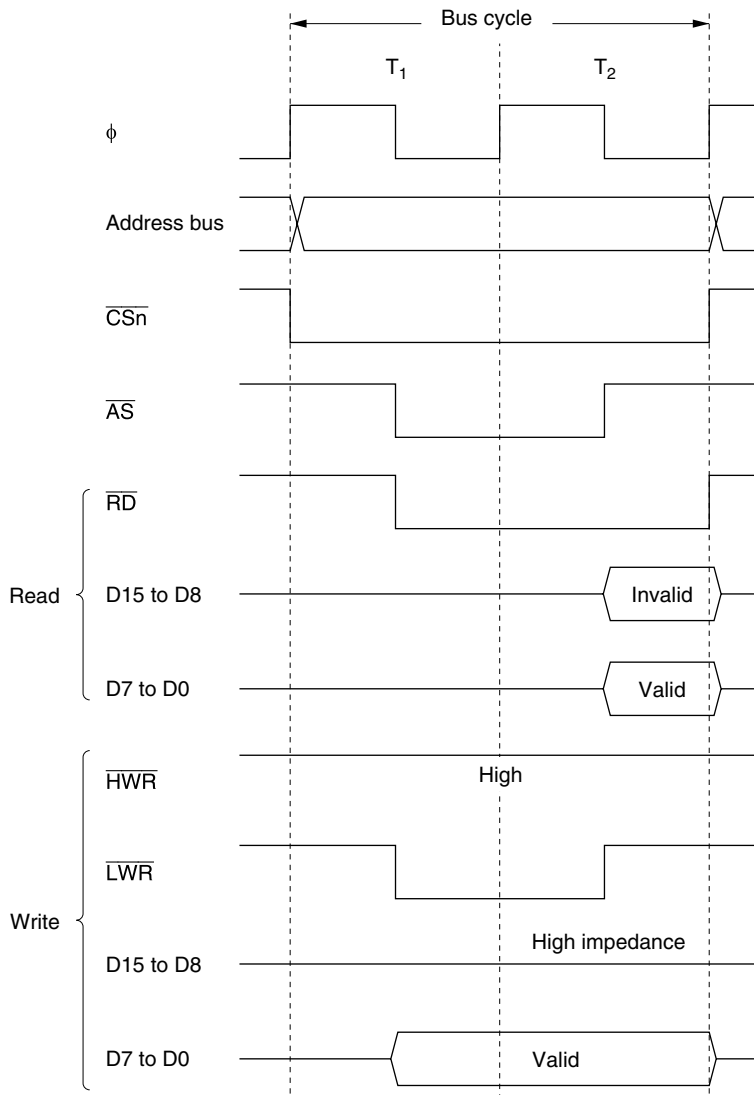

Figure 6.10 Bus Timing for 8-Bit, 3-State Access Space

16-Bit, 2-State Access Space: Figures 6.11 to 6.13 show bus timings for a 16-bit, 2-state access space. When a 16-bit access space is accessed, the upper half (D15 to D8) of the data bus is used for odd addresses, and the lower half (D7 to D0) for even addresses. Wait states cannot be inserted.

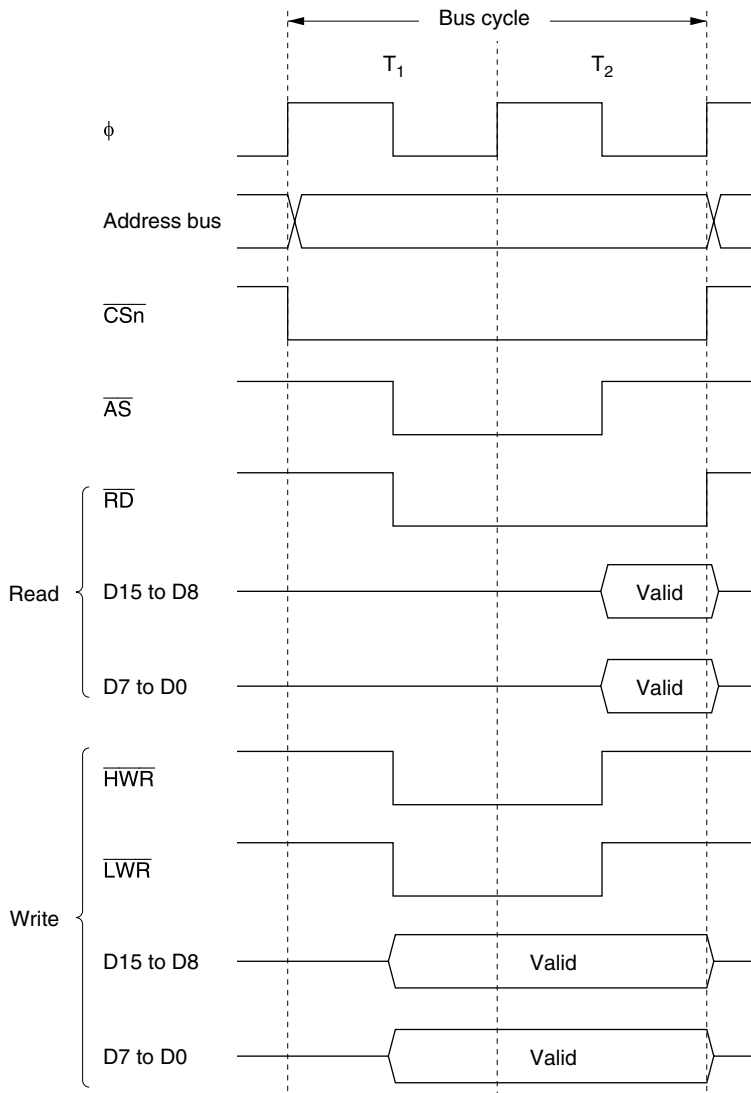

- Notes: 1. $n = 0$ to 7
2. When $RDNn = 0$

**Figure 6.11 Bus Timing for 16-Bit, 2-State Access Space
(Even Address Byte Access)**

- Notes: 1. $n = 0$ to 7
2. When $RDNn = 0$

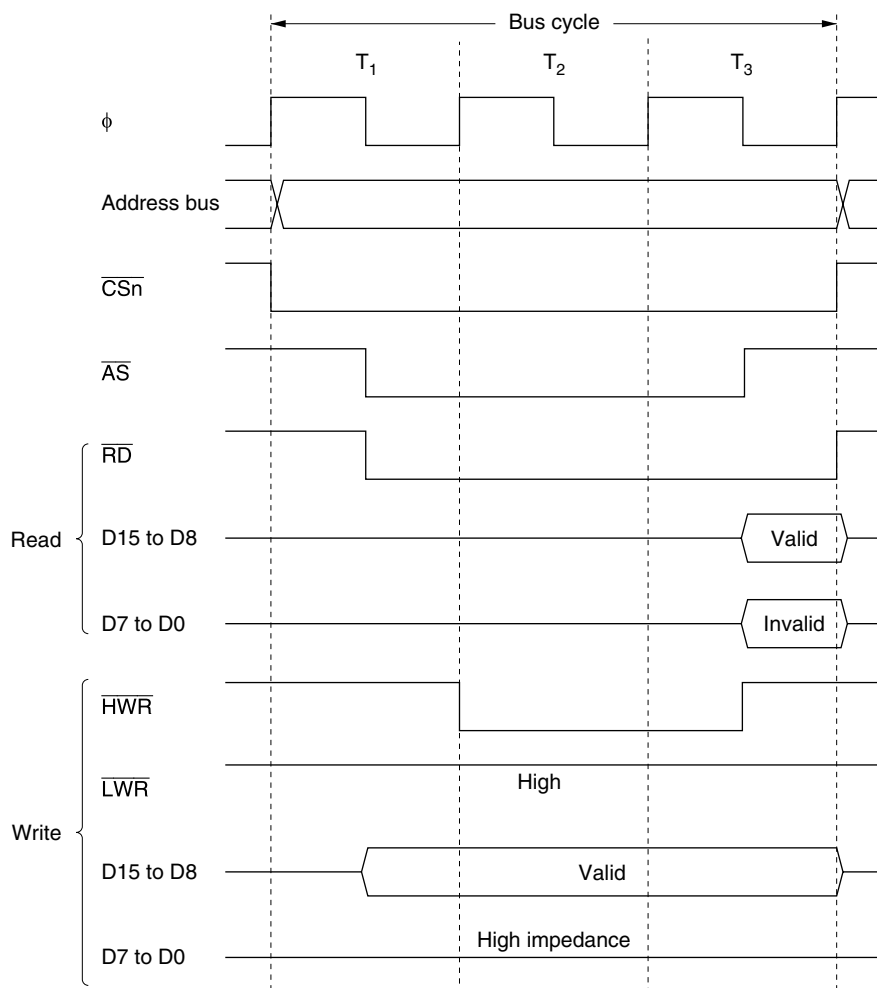

**Figure 6.12 Bus Timing for 16-Bit, 2-State Access Space
(Odd Address Byte Access)**

- Notes: 1. $n = 0$ to 7
2. When $RDNn = 0$

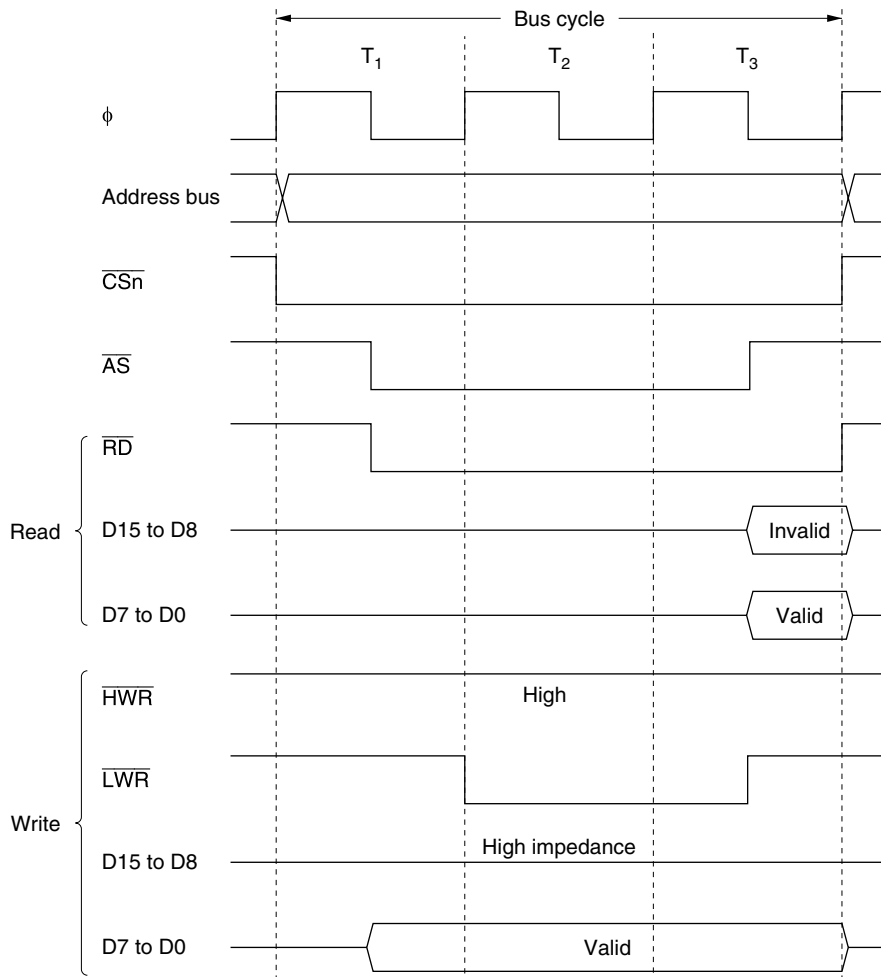

Figure 6.13 Bus Timing for 16-Bit, 2-State Access Space (Word Access)

16-Bit, 3-State Access Space: Figures 6.14 to 6.16 show bus timings for a 16-bit, 3-state access space. When a 16-bit access space is accessed, the upper half (D15 to D8) of the data bus is used for the even address, and the lower half (D7 to D0) for the odd address. Wait states can be inserted.

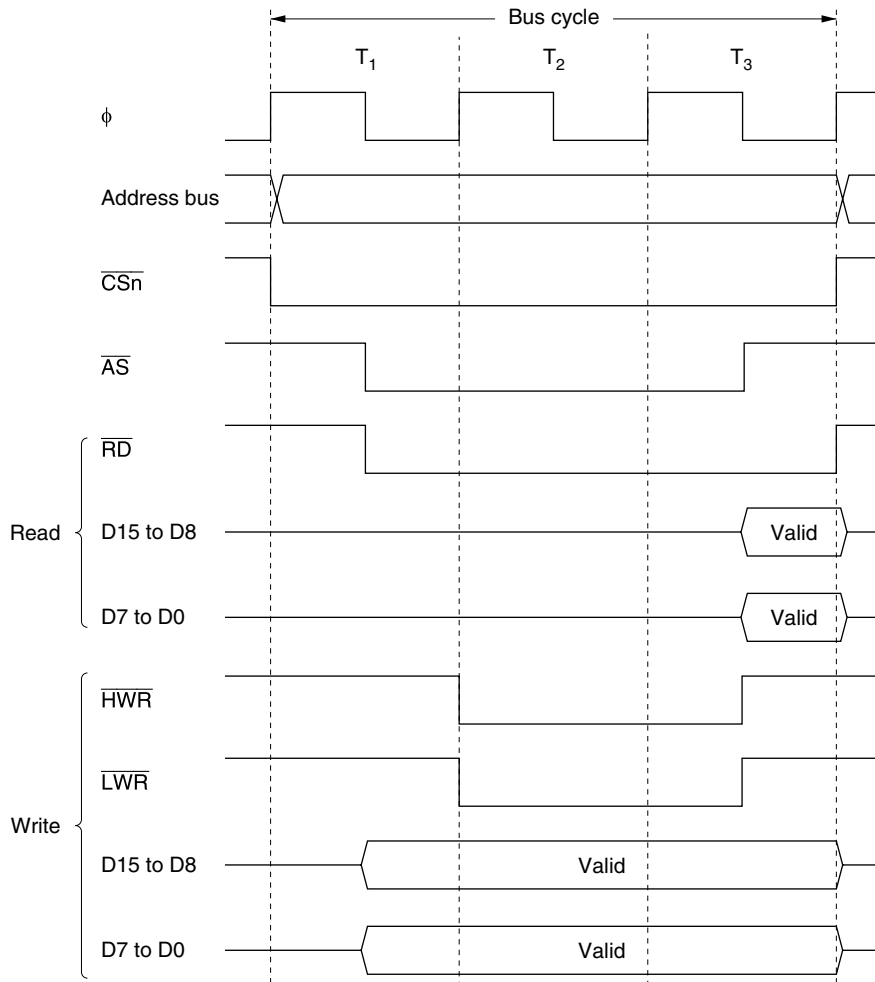

- Notes: 1. $n = 0$ to 7
2. When $RDNn = 0$

(Odd Address Byte Access)**

- Notes:
1. $n = 0$ to 7
 2. When $RDNn = 0$

**Figure 6.16 Bus Timing for 16-Bit, 3-State Access Space
(Word Access)**

6.5.4 Wait Control

When accessing external space, this LSI can extend the bus cycle by inserting one or more wait states (T_w). There are two ways of inserting wait states: program wait insertion and pin wait insertion using the $\overline{\text{WAIT}}$ pin.

Program Wait Insertion: From 0 to 7 wait states can be inserted automatically between the T_2 state and T_3 state on an individual area basis in 3-state access space, according to the settings in WTCRA and WTCRB.

Pin Wait Insertion: Setting the WAITE bit to 1 in BCR enables wait input by means of the $\overline{\text{WAIT}}$ pin. When external space is accessed in this state, a program wait is first inserted in accordance with the settings in WTCRA and WTCRB. If the $\overline{\text{WAIT}}$ pin is low at the falling edge of ϕ in the last T_2 or T_w state, another T_w state is inserted. If the $\overline{\text{WAIT}}$ pin is held low, T_w states are inserted until it goes high. This is useful when inserting seven or more T_w states, or when changing the number of T_w states to be inserted for different external devices. The WAITE bit setting applies to all areas. Figure 6.17 shows an example of wait state insertion timing.

The settings after a reset are: 3-state access, insertion of 7 program wait states, and $\overline{\text{WAIT}}$ input disabled.

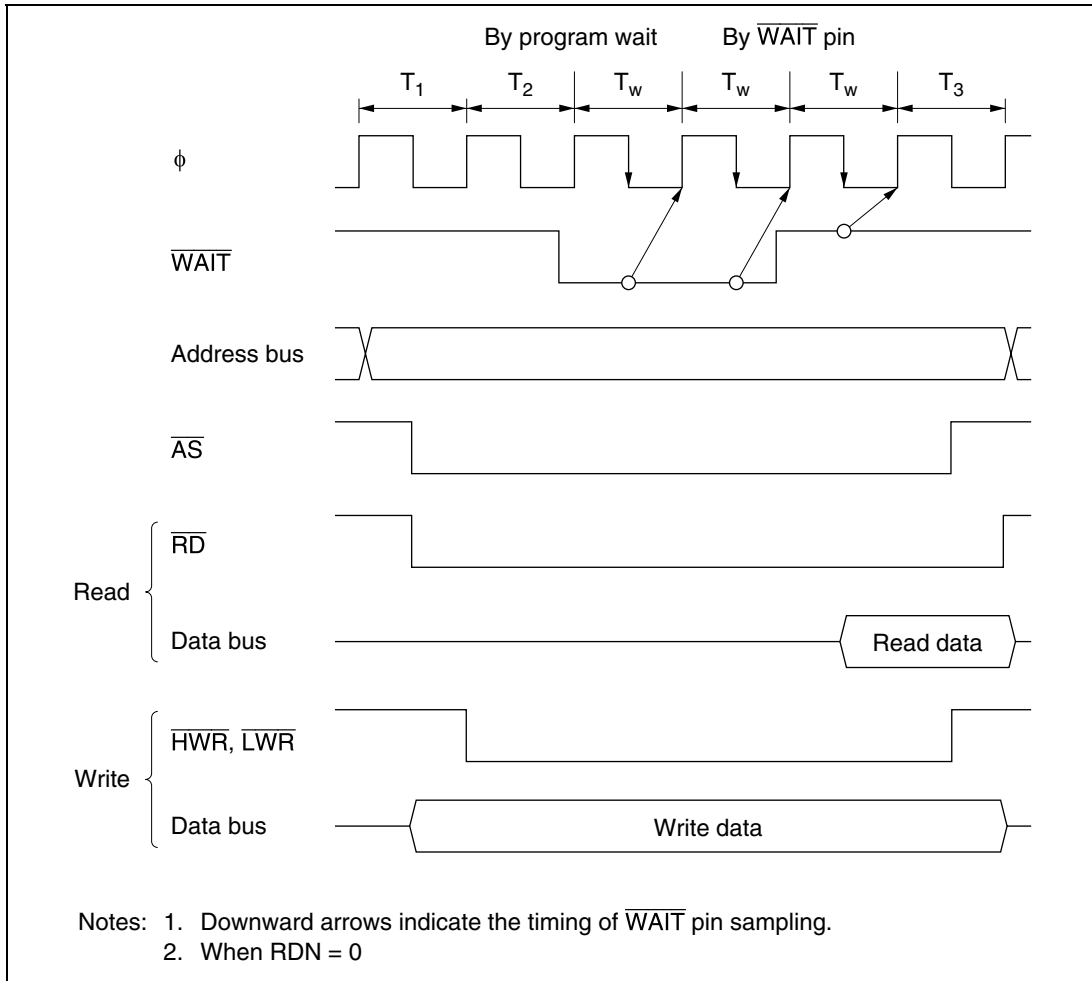

Figure 6.17 Example of Wait State Insertion Timing

6.5.5 Read Strobe ($\overline{\text{RD}}$) Timing

The read strobe ($\overline{\text{RD}}$) timing can be changed for individual areas by setting bits RDN7 to RDN0 to 1 in RDNCr . Figure 6.18 shows an example of the timing when the read strobe timing is changed in basic bus 3-state access space.

When the DMAC is used in single address mode, note that if the $\overline{\text{RD}}$ timing is changed by setting RDNn to 1, the $\overline{\text{RD}}$ timing will change relative to the rise of $\overline{\text{DACK}}$.

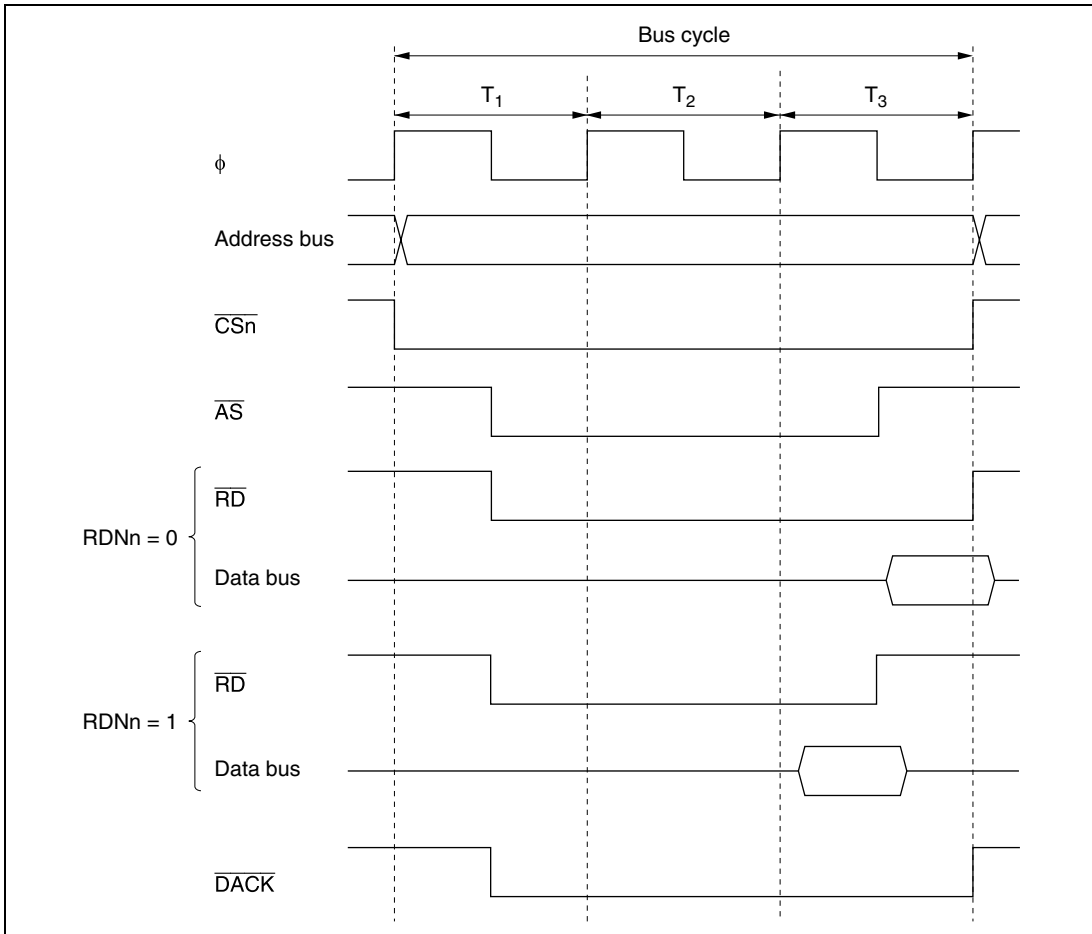

Figure 6.18 Example of Read Strobe Timing

6.5.6 Extension of Chip Select (\overline{CS}) Assertion Period

Some external I/O devices require a setup time and hold time between address and \overline{CS} signals and strobe signals such as \overline{RD} , \overline{HWR} , and \overline{LWR} . Settings can be made in the CSACR register to insert states in which only the \overline{CS} , \overline{AS} , and address signals are asserted before and after a basic bus space access cycle. Extension of the \overline{CS} assertion period can be set for individual areas. With the \overline{CS} assertion extension period in write access, the data setup and hold times are less stringent since the write data is output to the data bus.

Figure 6.19 shows an example of the timing when the \overline{CS} assertion period is extended in basic bus 3-state access space.

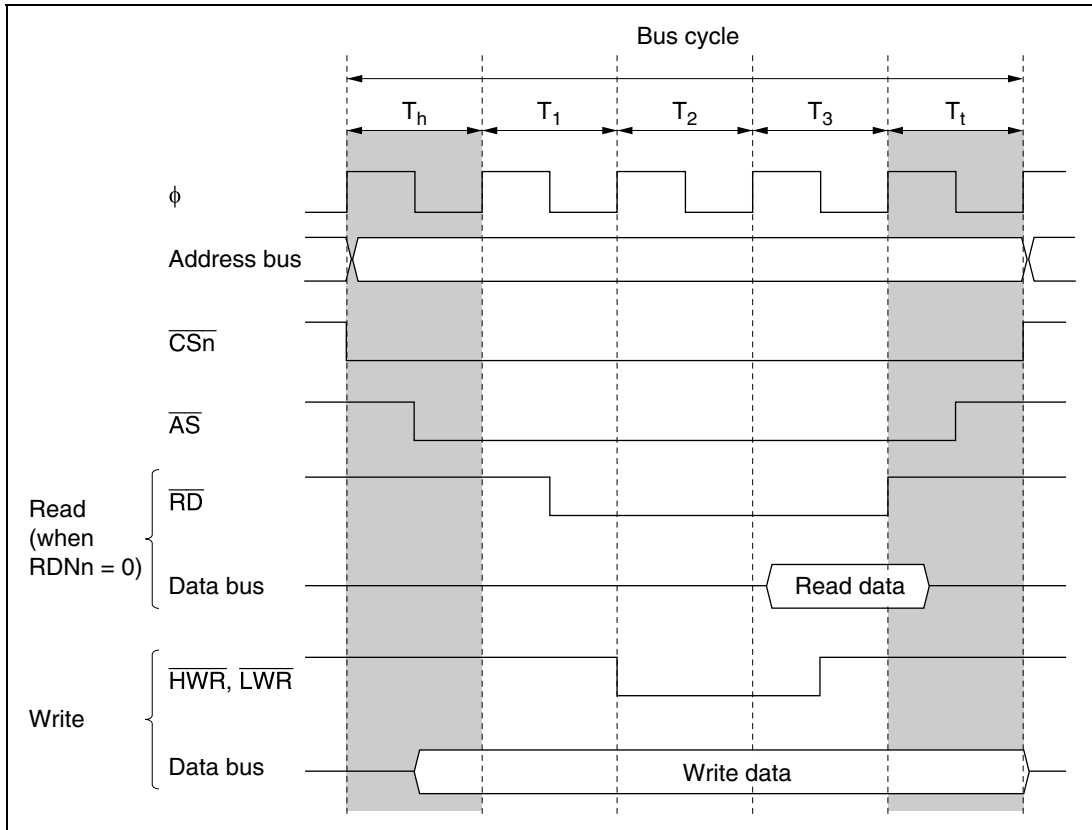

Figure 6.19 Example of Timing when Chip Select Assertion Period is Extended

Both extension state T_h inserted before the basic bus cycle and extension state T_t inserted after the basic bus cycle, or only one of these, can be specified for individual areas. Insertion or non-insertion can be specified for the T_h state with the upper 8 bits (CSXH7 to CSXH0) in the CSACR register, and for the T_t state with the lower 8 bits (CSXT7 to CSXT0).

6.6 DRAM Interface

In this LSI, external space areas 2 to 5 can be designated as DRAM space, and DRAM interfacing performed. The DRAM interface allows DRAM to be directly connected to this LSI. A DRAM space of 2, 4, or 8 Mbytes can be set by means of bits RMTS2 to RMTS0 in DRAMCR. Burst operation is also possible, using fast page mode.

Note: The DRAM interface is not supported by the H8S/2366.

6.6.1 Setting DRAM Space

Areas 2 to 5 are designated as DRAM space by setting bits RMTS2 to RMTS0 in DRAMCR. The relation between the settings of bits RMTS2 to RMTS0 and DRAM space is shown in table 6.4. Possible DRAM space settings are: one area (area 2), two areas (areas 2 and 3), and continuous area (areas 2 to 5).

Table 6.4 Relation between Settings of Bits RMTS2 to RMTS0 and DRAM Space

RMTS2	RMTS1	RMTS0	Area 5	Area 4	Area 3	Area 2
0	0	1	Normal space	Normal space	Normal space	DRAM space
		0	Normal space	Normal space	DRAM space	DRAM space
		1	Reserved (setting prohibited)			
1	0	0	Reserved (setting prohibited)			
		1	Reserved (setting prohibited)			
		0	Reserved (setting prohibited)			
	1	0	Reserved (setting prohibited)			
		1	Continuous DRAM space	Continuous DRAM space	Continuous DRAM space	Continuous DRAM space

With continuous DRAM space, $\overline{\text{RAS2}}$ is valid. The bus specifications (bus width, number of wait states, etc.) for continuous DRAM space conform to the settings for area 2.

6.6.2 Address Multiplexing

With DRAM space, the row address and column address are multiplexed. In address multiplexing, the size of the shift of the row address is selected with bits MXC2 to MXC0 in DRAMCR. Table 6.5 shows the relation between the settings of MXC2 to MXC0 and the shift size.

The MXC2 bit should be cleared to 0 when the DRAM interface is used.

Table 6.5 Relation between Settings of Bits MXC2 to MXC0 and Address Multiplexing

DRAMCR					Address Pins																	
					A23 to																	
	MXC2	MXC1	MXC0	Shift Size	A16	A15	A14	A13	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0	
Row address	0	0	0	8 bits	A23 to A16	A23	A23	A22	A21	A20	A19	A18	A17	A16	A15	A14	A13	A12	A11	A10	A9	A8
			1	9 bits	A23 to A16	A23	A15	A23	A22	A21	A20	A19	A18	A17	A16	A15	A14	A13	A12	A11	A10	A9
	1	0		10 bits	A23 to A16	A23	A15	A14	A23	A22	A21	A20	A19	A18	A17	A16	A15	A14	A13	A12	A11	A10
			1	11 bits	A23 to A16	A23	A15	A14	A13	A23	A22	A21	A20	A19	A18	A17	A16	A15	A14	A13	A12	A11
	1	X	X		Reserved (setting prohibited)																	
Column address	0	X	X	—	A23 to A16	A23	A15	A14	A13	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0
	1	X	X		Reserved (setting prohibited)																	

x: Don't care.

6.6.3 Data Bus

If a bit in ABWCR corresponding to an area designated as DRAM space is set to 1, that area is designated as 8-bit DRAM space; if the bit is cleared to 0, the area is designated as 16-bit DRAM space. In 16-bit DRAM space, ×16-bit configuration DRAM can be connected directly.

In 8-bit DRAM space the upper half of the data bus, D15 to D8, is enabled, while in 16-bit DRAM space both the upper and lower halves of the data bus, D15 to D0, are enabled.

Access sizes and data alignment are the same as for the basic bus interface: see section 6.5.1, Data Size and Data Alignment.

6.6.4 Pins Used for DRAM Interface

Table 6.6 shows the pins used for DRAM interfacing and their functions. Since the $\overline{\text{CS2}}$, $\overline{\text{CS5}}$ pins are in the input state after a reset, set the corresponding DDR to 1 when $\overline{\text{RAS2}}$, $\overline{\text{RAS5}}$ signals are output.

Table 6.6 DRAM Interface Pins

Pin	With DRAM Setting	Name	I/O	Function
$\overline{\text{HWR}}$	$\overline{\text{WE}}$	Write enable	Output	Write enable for DRAM space access
$\overline{\text{CS2}}$	$\overline{\text{RAS2}}$	Row address strobe 2/ row address strobe	Output	Row address strobe when area 2 is designated as DRAM space or row address strobe when areas 2 to 5 are designated as continuous DRAM space
$\overline{\text{CS3}}$	$\overline{\text{RAS3}}$	Row address strobe 3	Output	Row address strobe when area 3 is designated as DRAM space
$\overline{\text{UCAS}}$	$\overline{\text{UCAS}}$	Upper column address strobe	Output	Upper column address strobe for 16-bit DRAM space access or column address strobe for 8-bit DRAM space access
$\overline{\text{LCAS}}$	$\overline{\text{LCAS}}$	Lower column address strobe	Output	Lower column address strobe signal for 16-bit DRAM space access
$\overline{\text{RD}}$, $\overline{\text{OE}}$	$\overline{\text{OE}}$	Output enable	Output	Output enable signal for DRAM space access
$\overline{\text{WAIT}}$	$\overline{\text{WAIT}}$	Wait	Input	Wait request signal
A15 to A0	A15 to A0	Address pins	Output	Row address/column address multiplexed output
D15 to D0	D15 to D0	Data pins	I/O	Data input/output pins

6.6.5 Basic Timing

Figure 6.20 shows the basic access timing for DRAM space.

The four states of the basic timing consist of one T_p (precharge cycle) state, one T_r (row address output cycle) state, and the T_{c1} and two T_{c2} (column address output cycle) states.

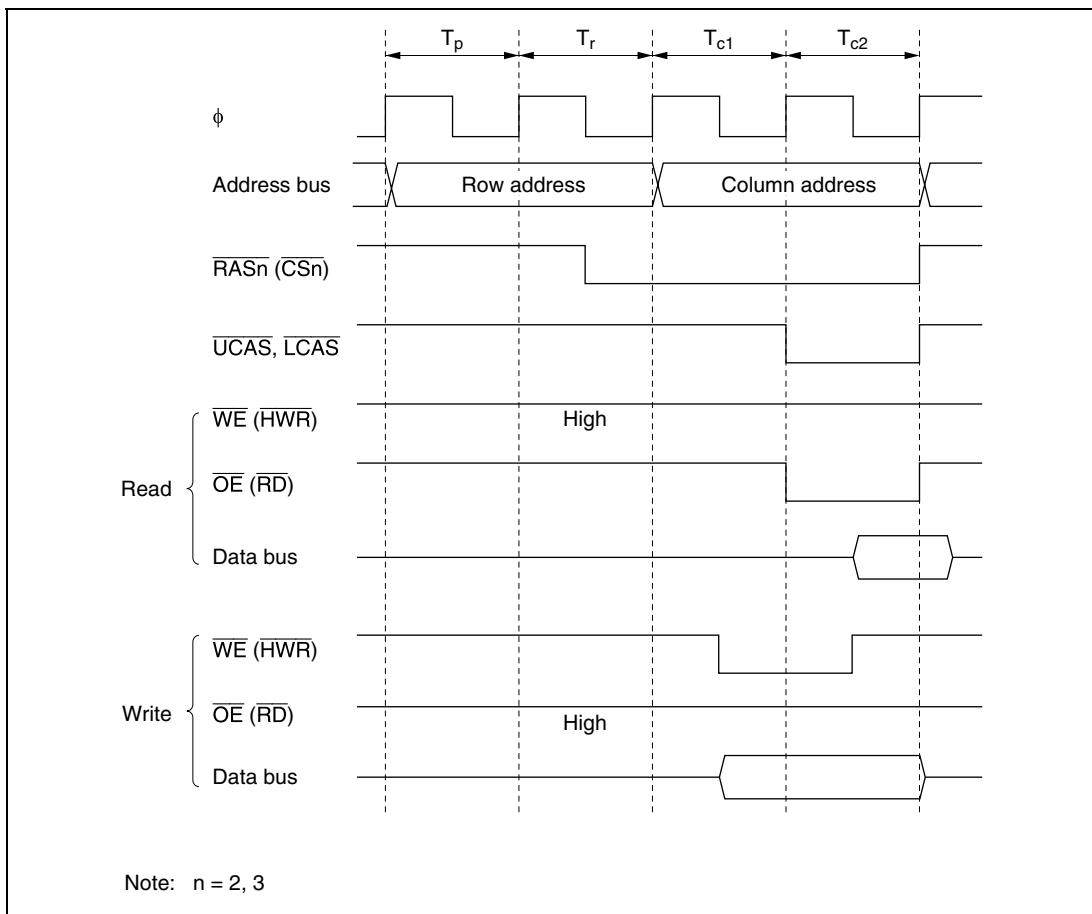

Figure 6.20 DRAM Basic Access Timing (RAST = 0, CAST = 0)

When DRAM space is accessed, the \overline{RD} signal is output as the \overline{OE} signal for DRAM. When connecting DRAM provided with an EDO page mode, the \overline{OE} signal should be connected to the (\overline{OE}) pin of the DRAM. Setting the \overline{OEE} bit to 1 in DRAMCR enables the \overline{OE} signal for DRAM space to be output from a dedicated \overline{OE} pin. In this case, the \overline{OE} signal for DRAM space is output from both the \overline{RD} pin and the (\overline{OE}) pin, but in external read cycles for other than DRAM space, the signal is output only from the \overline{RD} pin.

6.6.6 Column Address Output Cycle Control

The column address output cycle can be changed from 2 states to 3 states by setting the CAST bit to 1 in DRAMCR. Use the setting that gives the optimum specification values ($\overline{\text{CAS}}$ pulse width, etc.) according to the DRAM connected and the operating frequency of this LSI. Figure 6.21 shows an example of the timing when a 3-state column address output cycle is selected.

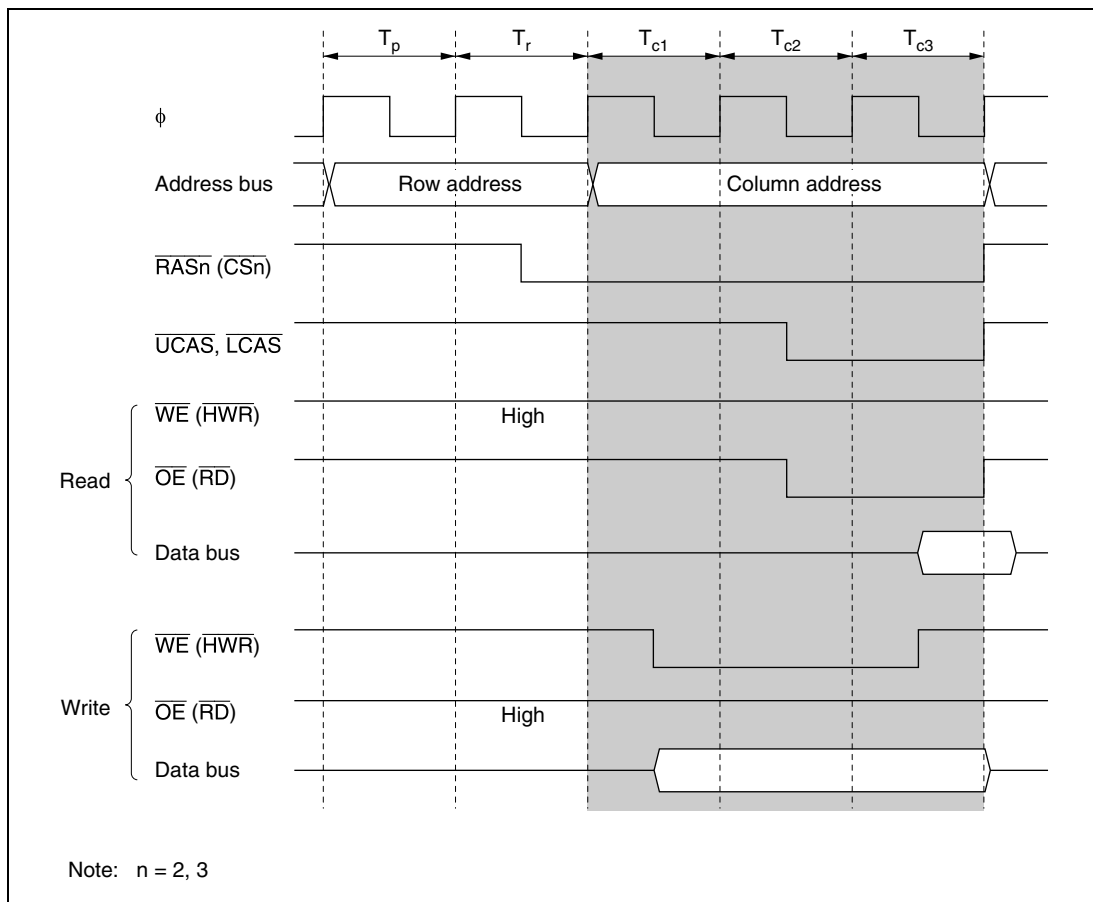

Figure 6.21 Example of Access Timing with 3-State Column Address Output Cycle ($\text{RAST} = 0$)

6.6.7 Row Address Output State Control

If the RAST bit is set to 1 in DRAMCR, the $\overline{\text{RAS}}$ signal goes low from the beginning of the T_r state, and the row address hold time and DRAM read access time are changed relative to the fall of the RAS signal. Use the optimum setting according to the DRAM connected and the operating

frequency of this LSI. Figure 6.22 shows an example of the timing when the $\overline{\text{RAS}}$ signal goes low from the beginning of the T_r state.

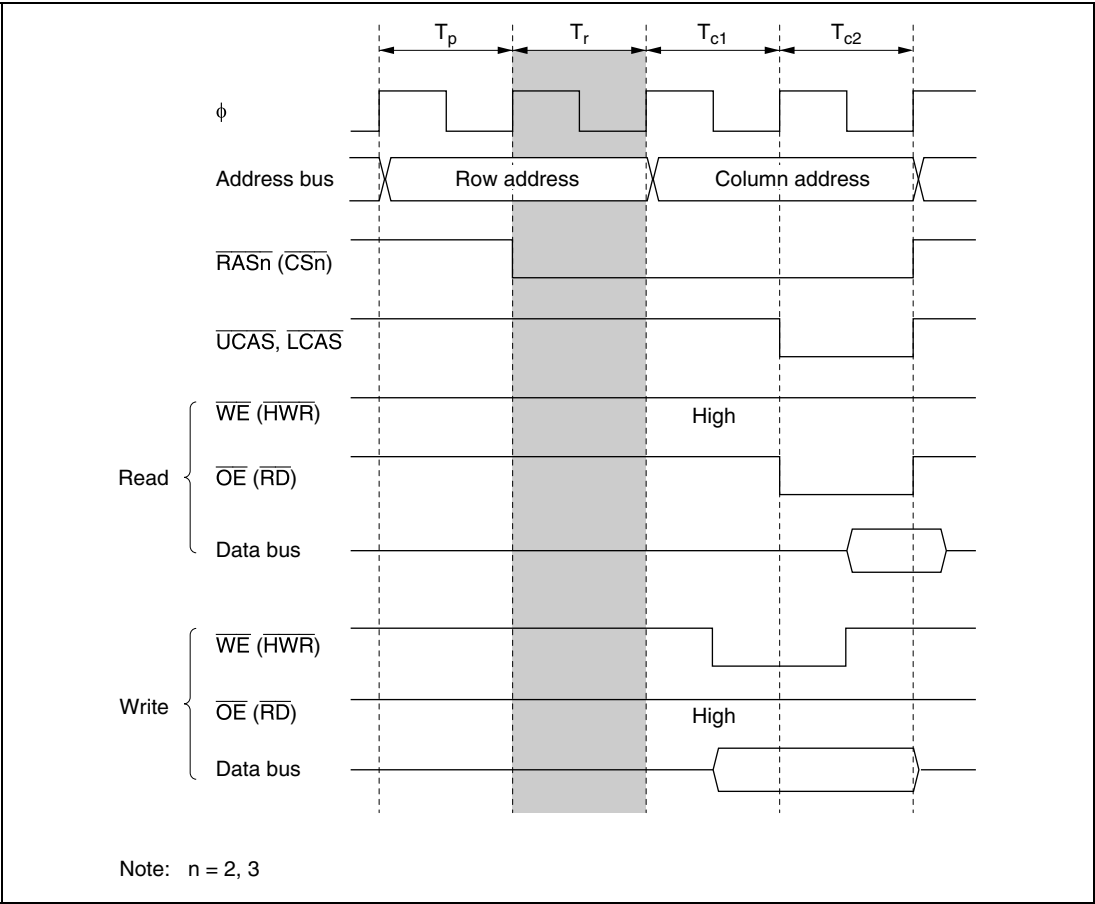

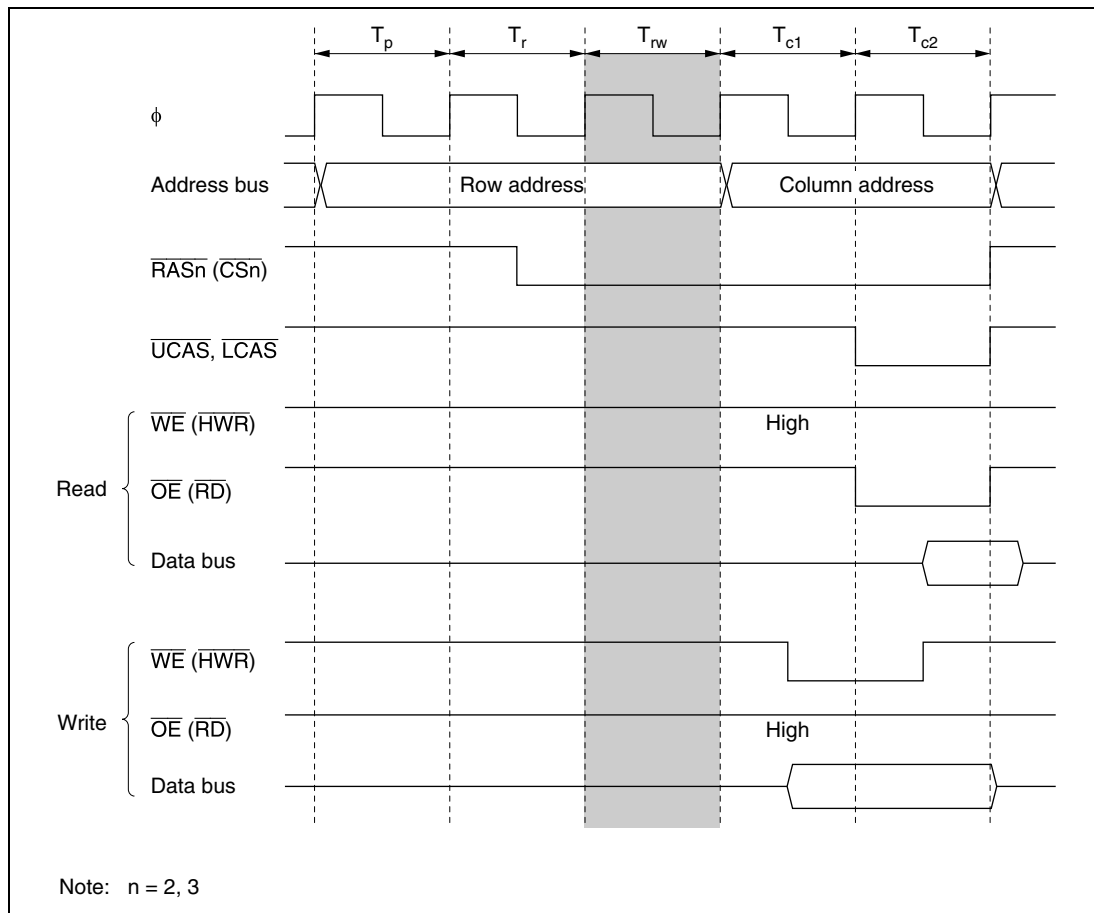

Figure 6.22 Example of Access Timing when $\overline{\text{RAS}}$ Signal Goes Low from Beginning of T_r State (CAST = 0)

If a row address hold time or read access time is necessary, making a setting in bits RCD1 and RCD0 in DRACCR allows from one to three T_{rw} states, in which row address output is maintained, to be inserted between the T_r cycle, in which the \overline{RAS} signal goes low, and the T_{c1} cycle, in which the column address is output. Use the setting that gives the optimum row address signal hold time relative to the falling edge of the \overline{RAS} signal according to the DRAM connected and the operating frequency of this LSI. Figure 6.23 shows an example of the timing when one T_{rw} state is set.

**Figure 6.23 Example of Timing with One Row Address Output Maintenance State
(RAST = 0, CAST = 0)**

6.6.8 Precharge State Control

When DRAM is accessed, a $\overline{\text{RAS}}$ precharge time must be secured. With this LSI, one T_p state is always inserted when DRAM space is accessed. From one to four T_p states can be selected by setting bits TPC1 and TPC0 in DRACCR. Set the optimum number of T_p cycles according to the DRAM connected and the operating frequency of this LSI. Figure 6.24 shows the timing when two T_p states are inserted. The setting of bits TPC1 and TPC0 is also valid for T_p states in refresh cycles.

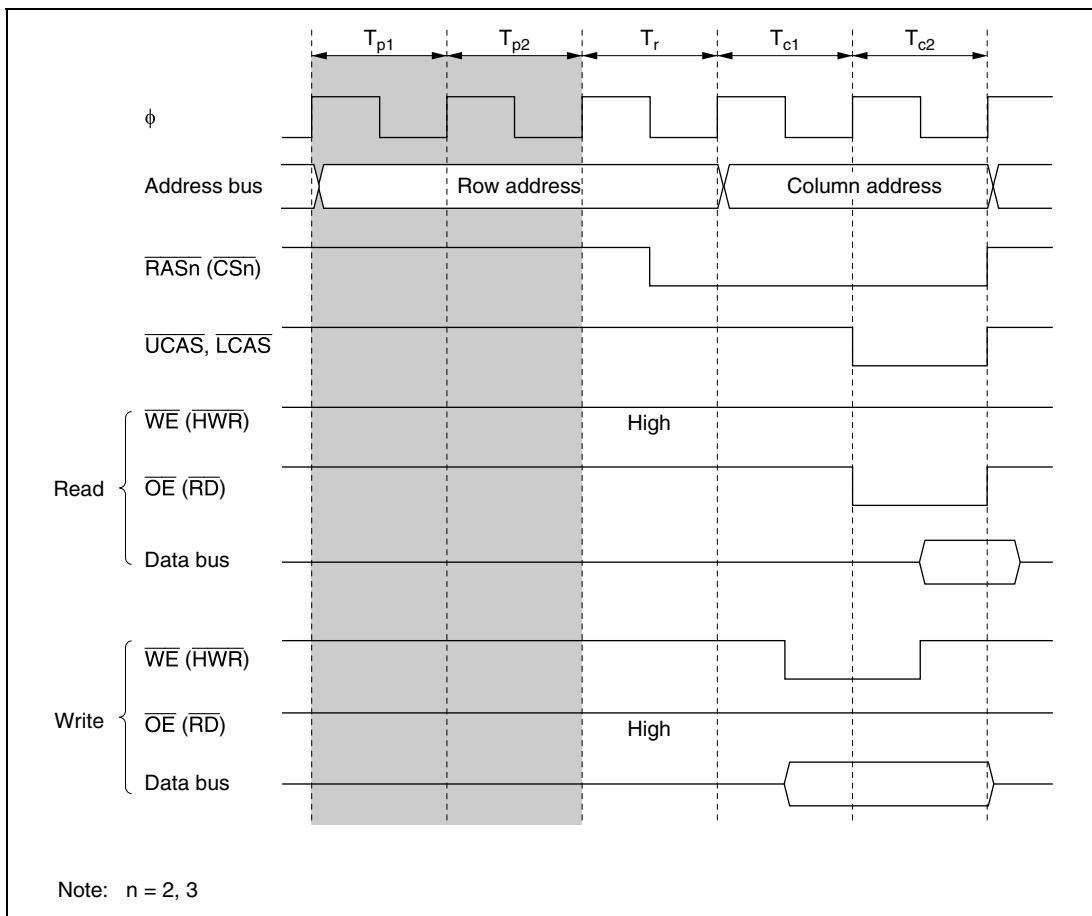

Figure 6.24 Example of Timing with Two-State Precharge Cycle
($\text{RAST} = 0, \text{CAST} = 0$)

6.6.9 Wait Control

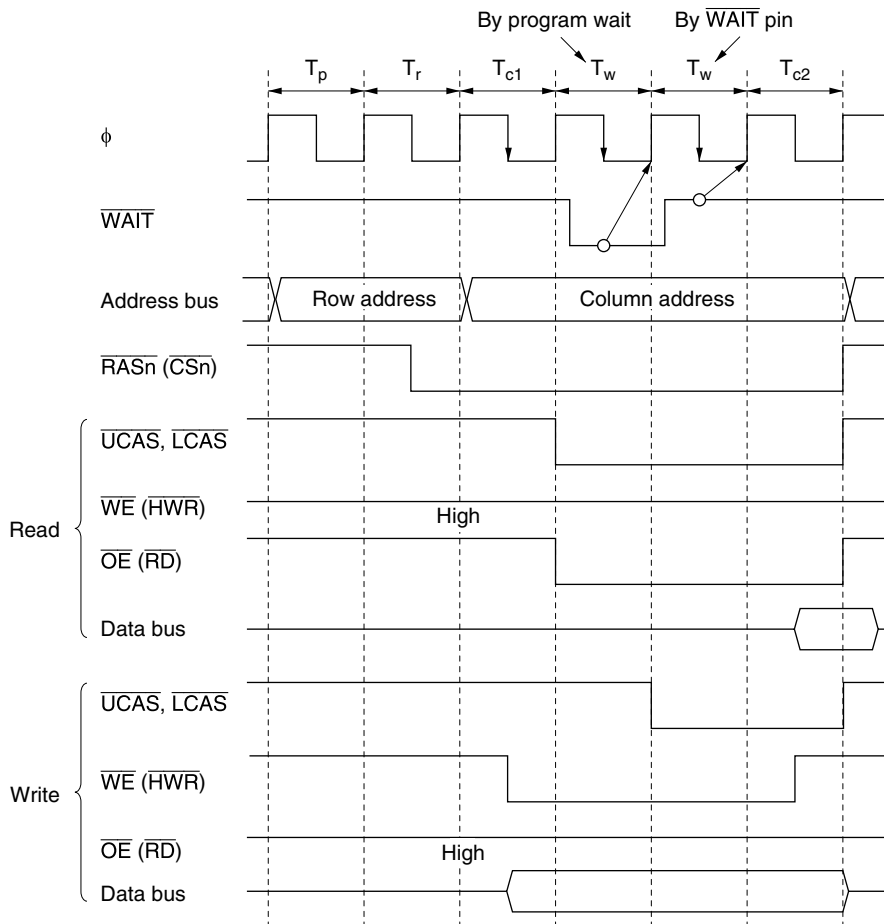

There are two ways of inserting wait states in a DRAM access cycle: program wait insertion and pin wait insertion using the $\overline{\text{WAIT}}$ pin.

Wait states are inserted to extend the $\overline{\text{CAS}}$ assertion period in a read access to DRAM space, and to extend the write data setup time relative to the falling edge of $\overline{\text{CAS}}$ in a write access.

Program Wait Insertion: When the bit in ASTCR corresponding to an area designated as DRAM space is set to 1, from 0 to 7 wait states can be inserted automatically between the T_{c1} state and T_{c2} state, according to the WTCR setting.

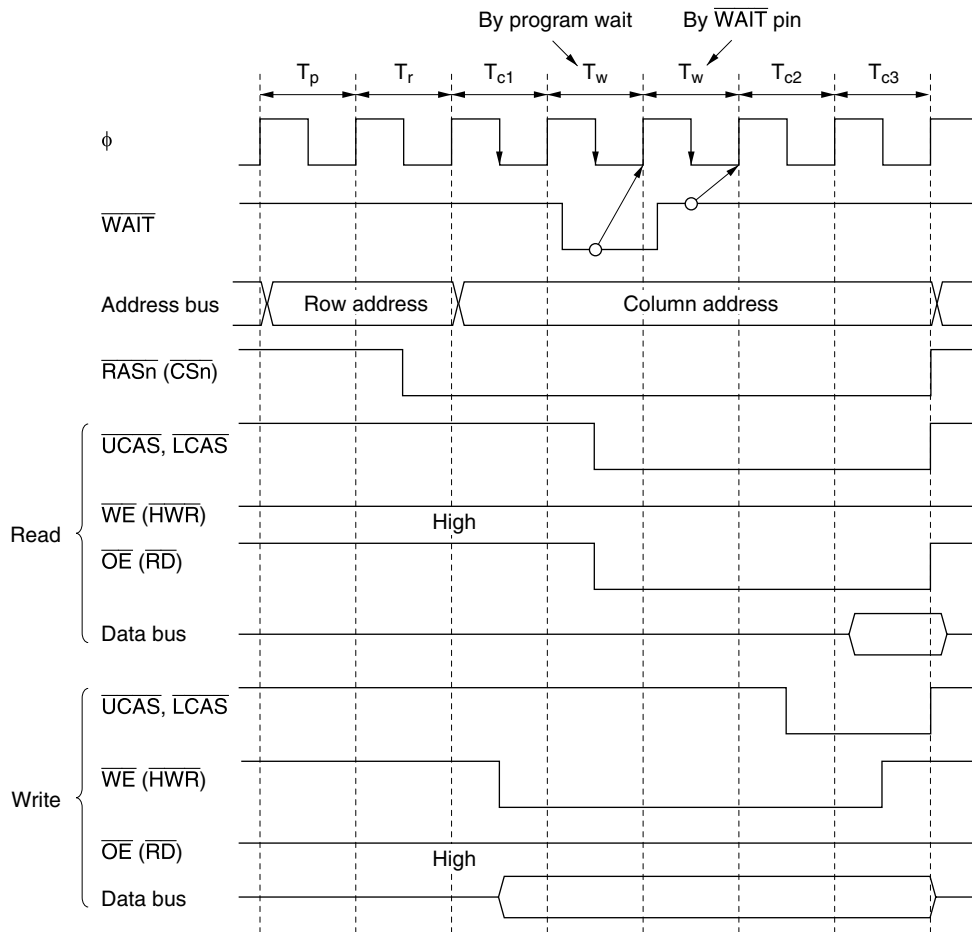

Pin Wait Insertion: When the WAITE bit in BCR is set to 1 and the ASTCR bit is set to 1, wait input by means of the $\overline{\text{WAIT}}$ pin is enabled. When DRAM space is accessed in this state, a program wait (T_w) is first inserted. If the $\overline{\text{WAIT}}$ pin is low at the falling edge of ϕ in the last T_{c1} or T_w state, another T_w state is inserted. If the $\overline{\text{WAIT}}$ pin is held low, T_w states are inserted until it goes high.

Figures 6.25 and 6.26 show examples of wait cycle insertion timing in the case of 2-state and 3-state column address output cycles.

Notes: Downward arrows indicate the timing of \overline{WAIT} pin sampling.
 $n = 2, 3$

**Figure 6.25 Example of Wait State Insertion Timing
 (2-State Column Address Output)**

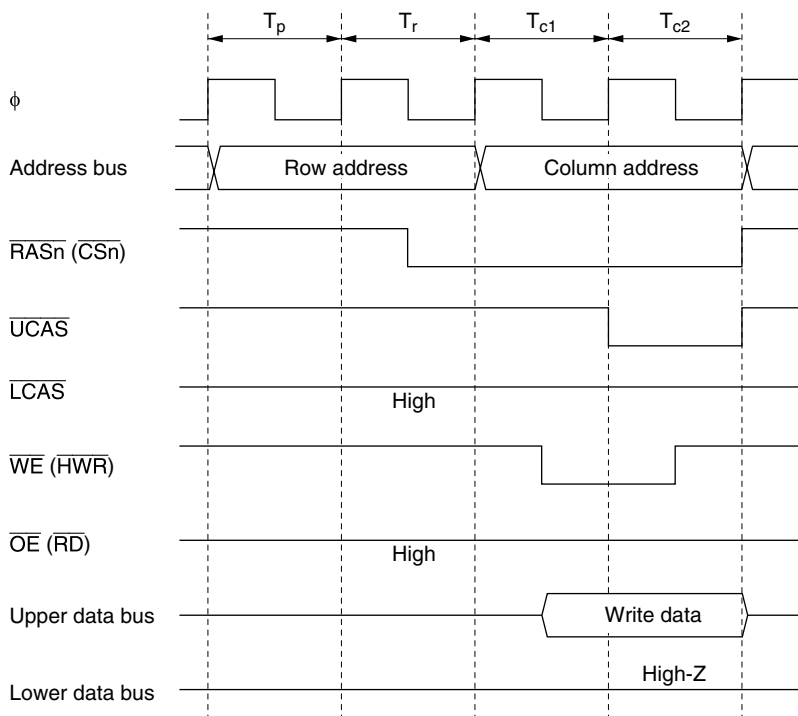

Notes: Downward arrows indicate the timing of \overline{WAIT} pin sampling.
 $n = 2, 3$

**Figure 6.26 Example of Wait State Insertion Timing
 (3-State Column Address Output)**

6.6.10 Byte Access Control

When DRAM with a $\times 16$ -bit configuration is connected, the 2-CAS access method is used for the control signals needed for byte access. Figure 6.27 shows the control timing for 2-CAS access, and figure 6.28 shows an example of 2-CAS DRAM connection.

Note: $n = 2, 3$

Figure 6.27 2-CAS Control Timing
(Upper Byte Write Access: $RAST = 0$, $CAST = 0$)

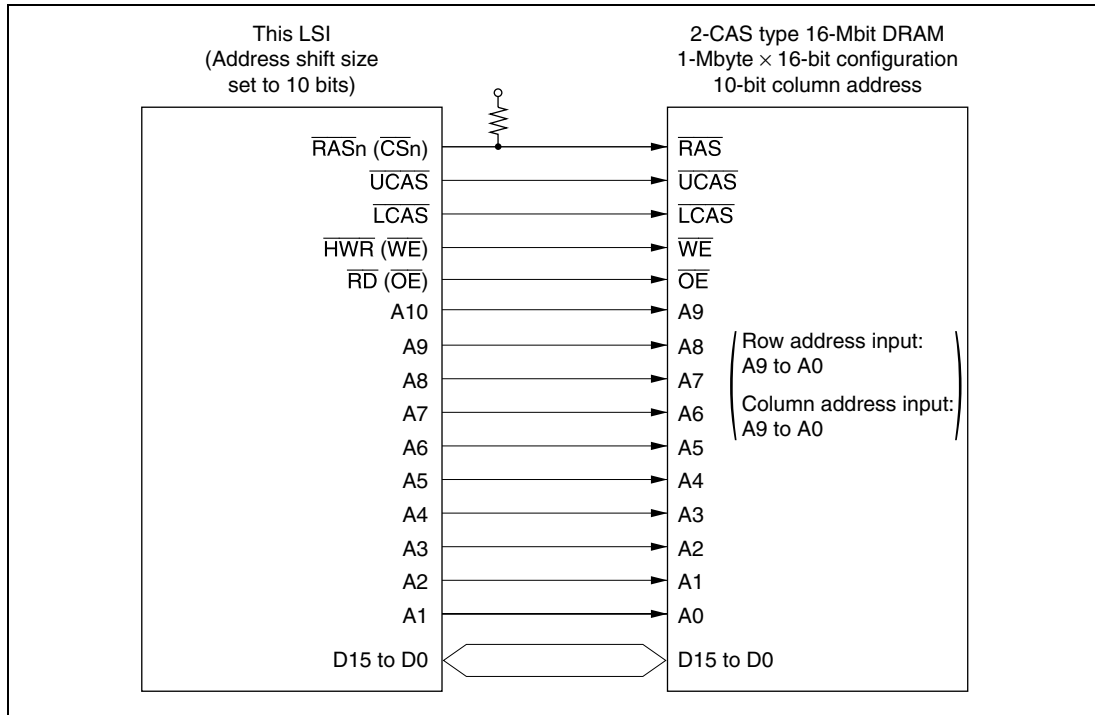

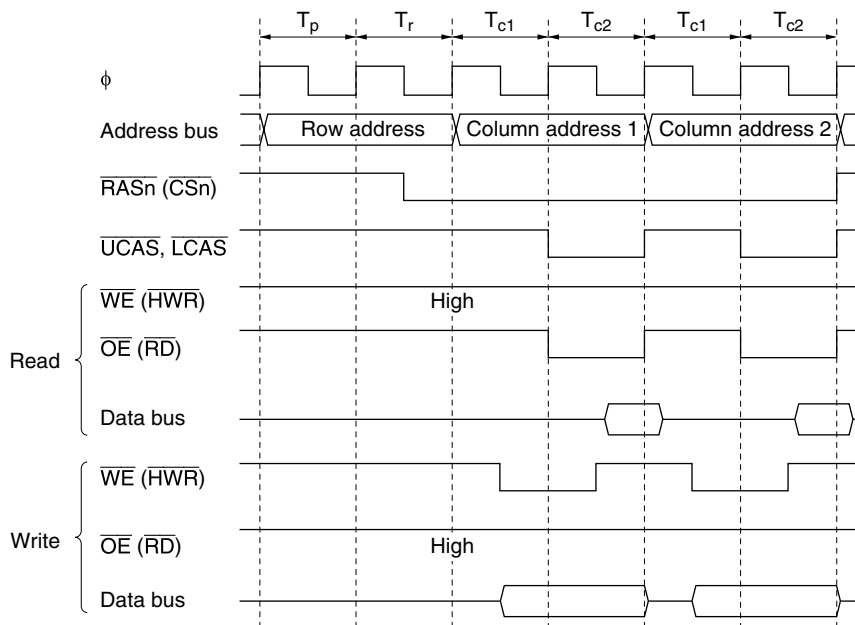

Figure 6.28 Example of 2-CAS DRAM Connection

6.6.11 Burst Operation

With DRAM, in addition to full access (normal access) in which data is accessed by outputting a row address for each access, a fast page mode is also provided which can be used when making consecutive accesses to the same row address. This mode enables fast (burst) access of data by simply changing the column address after the row address has been output. Burst access can be selected by setting the BE bit to 1 in DRAMCR.

Burst Access (Fast Page Mode): Figures 6.29 and 6.30 show the operation timing for burst access. When there are consecutive access cycles for DRAM space, the \overline{CAS} signal and column address output cycles (two states) continue as long as the row address is the same for consecutive access cycles. The row address used for the comparison is set with bits MXC2 to MXC0 in DRAMCR.

Note: $n = 2, 3$

Figure 6.29 Operation Timing in Fast Page Mode
(RAST = 0, CAST = 0)

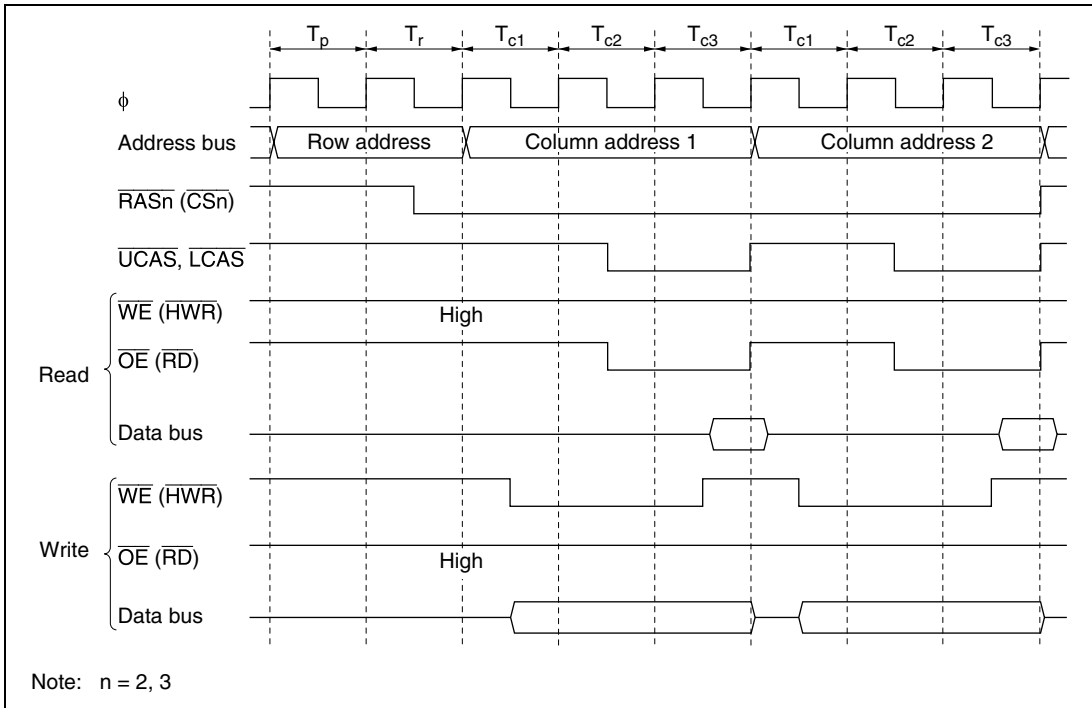

Figure 6.30 Operation Timing in Fast Page Mode
(RAST = 0, CAST = 1)

The bus cycle can also be extended in burst access by inserting wait states. The wait state insertion method and timing are the same as for full access. For details see section 6.6.9, Wait Control.

RAS Down Mode and RAS Up Mode: Even when burst operation is selected, it may happen that access to DRAM space is not continuous, but is interrupted by access to another space. In this case, if the $\overline{\text{RAS}}$ signal is held low during the access to the other space, burst operation can be resumed when the same row address in DRAM space is accessed again.

- **RAS Down Mode**

To select RAS down mode, set both the RCDM bit and the BE bit to 1 in DRAMCR. If access to DRAM space is interrupted and another space is accessed, the $\overline{\text{RAS}}$ signal is held low during the access to the other space, and burst access is performed when the row address of the next DRAM space access is the same as the row address of the previous DRAM space access. Figure 6.31 shows an example of the timing in RAS down mode.

Note, however, that the $\overline{\text{RAS}}$ signal will go high if:

- a refresh operation is initiated in the RAS down state
- self-refreshing is performed
- the chip enters software standby mode
- the external bus is released

— the RCDM bit or BE bit is cleared to 0

If a transition is made to the all-module-clocks-stopped mode in the $\overline{\text{RAS}}$ down state, the clock will stop with $\overline{\text{RAS}}$ low. To enter the all-module-clocks-stopped mode with $\overline{\text{RAS}}$ high, the RCDM bit must be cleared to 0 before executing the SLEEP instruction.

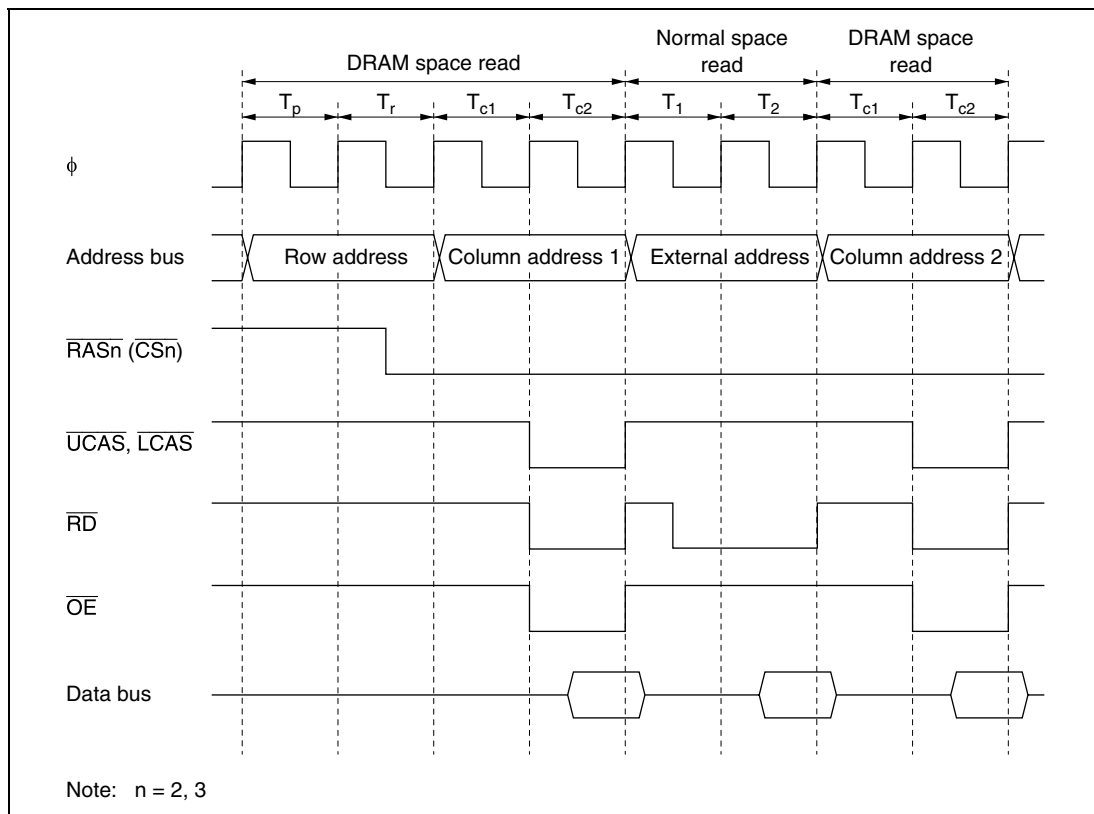

Figure 6.31 Example of Operation Timing in RAS Down Mode
($\text{RAST} = 0$, $\text{CAST} = 0$)

- RAS Up Mode

To select RAS up mode, clear the RCDM bit to 0 in DRAMCR. Each time access to DRAM space is interrupted and another space is accessed, the $\overline{\text{RAS}}$ signal goes high again. Burst operation is only performed if DRAM space is continuous. Figure 6.32 shows an example of the timing in RAS up mode.

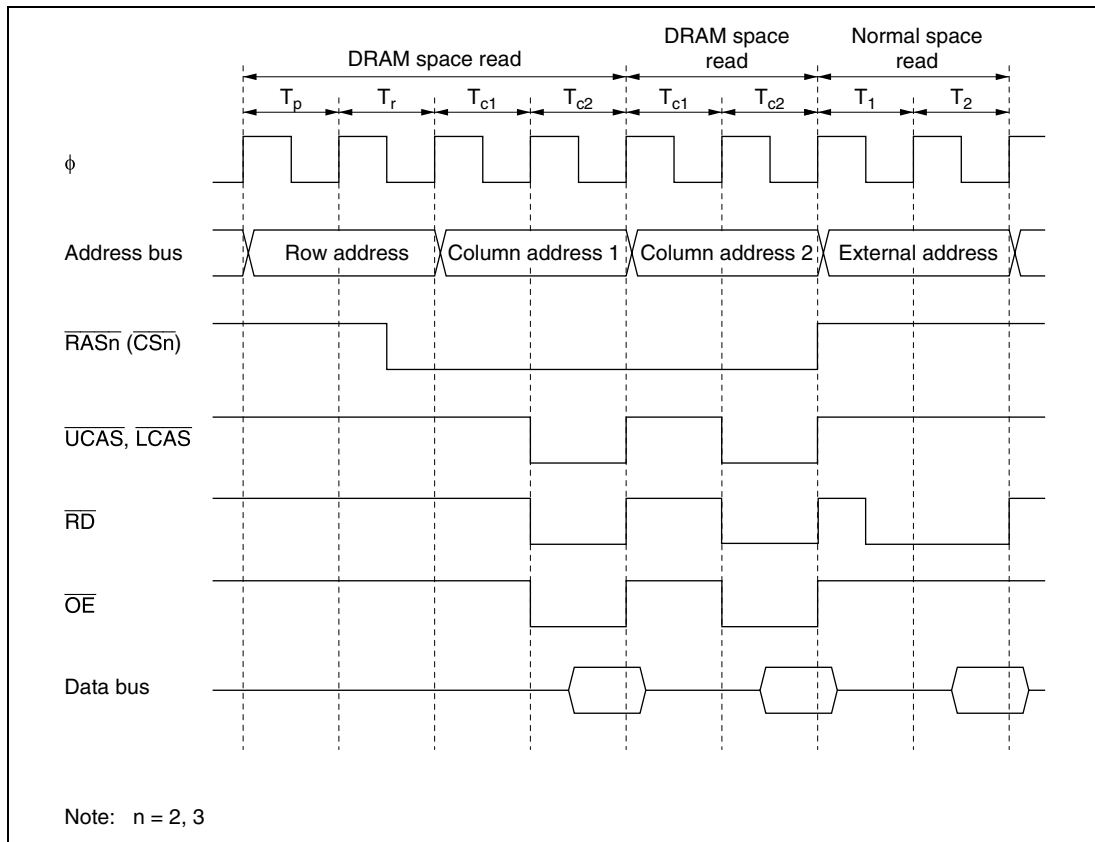

Figure 6.32 Example of Operation Timing in RAS Up Mode
($\text{RAST} = 0$, $\text{CAST} = 0$)

6.6.12 Refresh Control

This LSI is provided with a DRAM refresh control function. CAS-before-RAS (CBR) refreshing is used. In addition, self-refreshing can be executed when the chip enters the software standby state.

Refresh control is enabled when any area is designated as DRAM space in accordance with the setting of bits RMTS2 to RMTS0 in DRAMCR.

CAS-before-RAS (CBR) Refreshing: To select CBR refreshing, set the RFSHE bit to 1 in REFCR.

With CBR refreshing, RTCNT counts up using the input clock selected by bits RTCK2 to RTCK0 in REFCR, and when the count matches the value set in RTCOR (compare match), refresh control is performed. At the same time, RTCNT is reset and starts counting up again from H'00. Refreshing is thus repeated at fixed intervals determined by RTCOR and bits RTCK2 to RTCK0. Set a value in RTCOR and bits RTCK2 to RTCK0 that will meet the refreshing interval specification for the DRAM used.

When bits RTCK2 to RTCK0 in REFCR are set, RTCNT starts counting up. RTCNT and RTCOR settings should therefore be completed before setting bits RTCK2 to RTCK0. RTCNT operation is shown in figure 6.33, compare match timing in figure 6.34, and CBR refresh timing in figure 6.35.

When the CBRM bit in REFCR is cleared to 0, access to external space other than DRAM space is performed in parallel during the CBR refresh period.

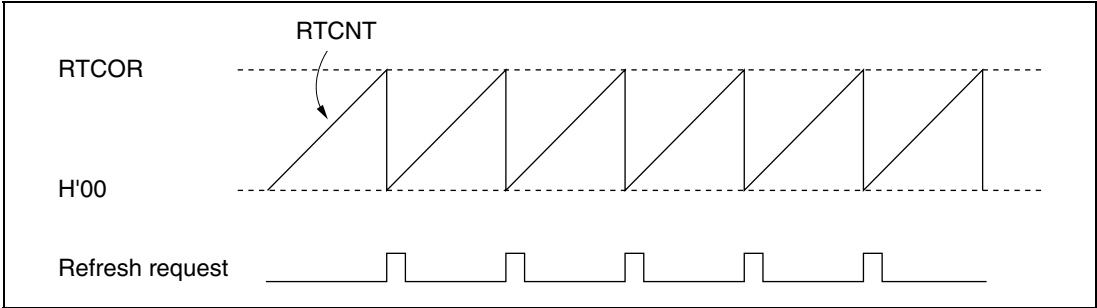

Figure 6.33 RTCNT Operation

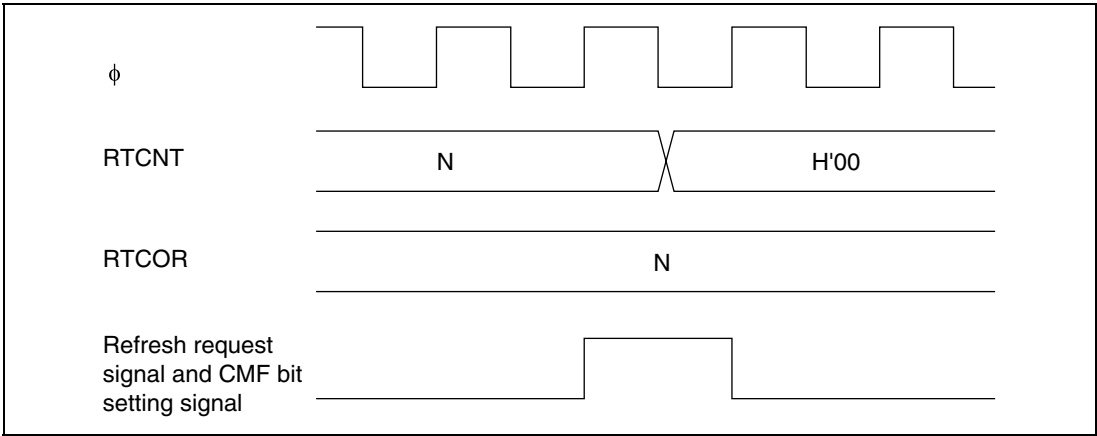

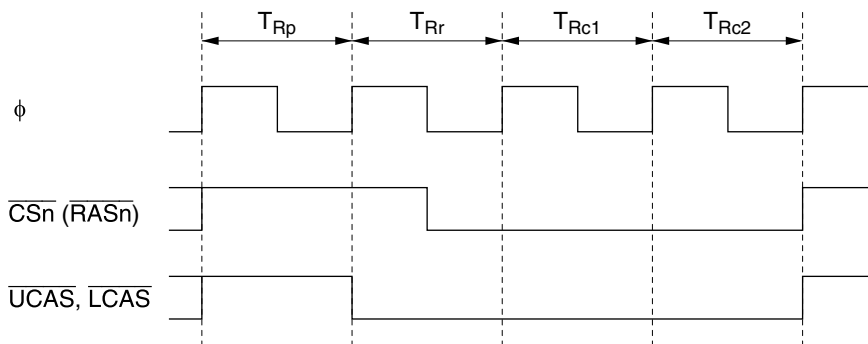

Figure 6.34 Compare Match Timing

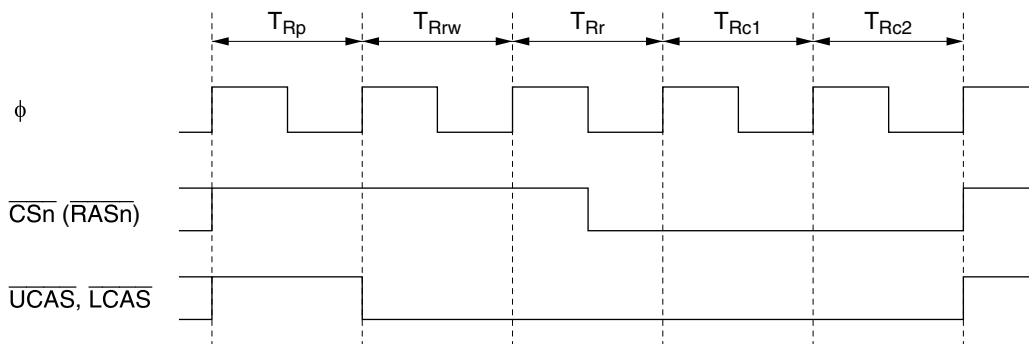

Note: $n = 2, 3$

Figure 6.35 CBR Refresh Timing

A setting can be made in bits RCW1 and RCW0 in REFCR to delay $\overline{\text{RAS}}$ signal output by one to three cycles. Use bits RLW1 and RLW0 in REFCR to adjust the width of the $\overline{\text{RAS}}$ signal. The settings of bits RCW1, RCW0, RLW1, and RLW0 are valid only in refresh operations.

Figure 6.36 shows the timing when bits RCW1 and RCW0 are set.

Note: $n = 2, 3$

Figure 6.36 CBR Refresh Timing
(RCW1 = 0, RCW0 = 1, RLW1 = 0, RLW0 = 0)

Depending on the DRAM used, modification of the $\overline{\text{WE}}$ signal may not be permitted during the refresh period. In this case, the CBRM bit in REFCR should be set to 1. The bus controller will then insert refresh cycles in appropriate breaks between bus cycles. Figure 6.37 shows an example of the timing when the CBRM bit is set to 1. In this case the $\overline{\text{CS}}$ signal is not controlled, and retains its value prior to the start of the refresh period.

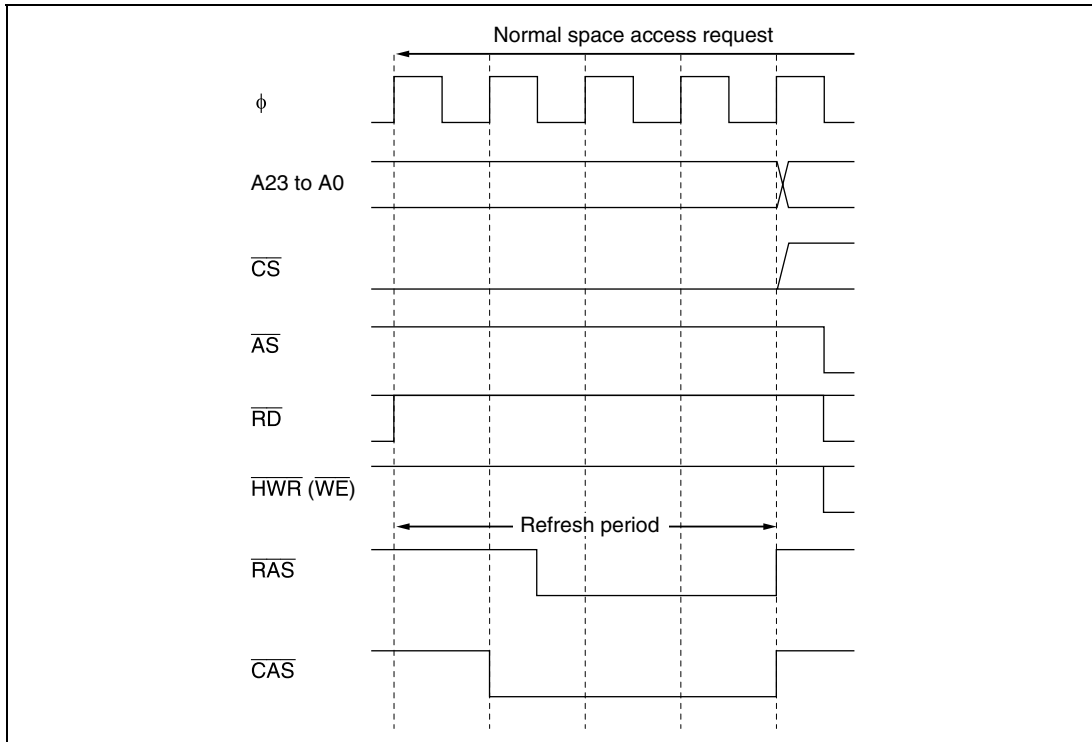

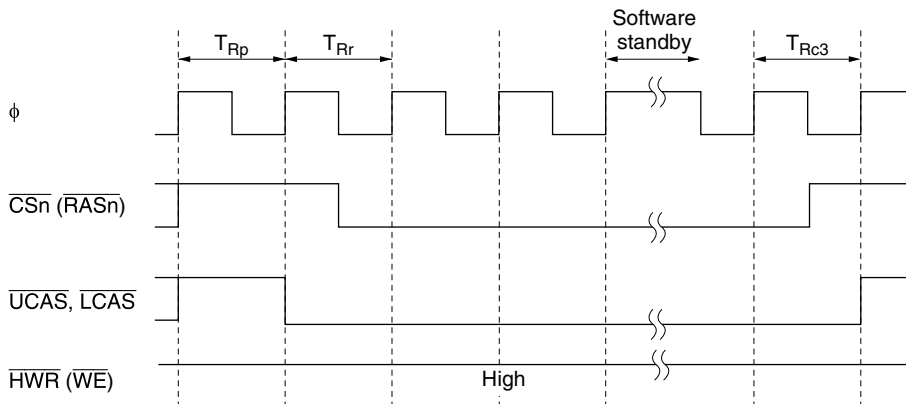

Figure 6.37 Example of CBR Refresh Timing (CBRM = 1)

Self-Refreshing: A self-refresh mode (battery backup mode) is provided for DRAM as a kind of standby mode. In this mode, refresh timing and refresh addresses are generated within the DRAM.

To select self-refreshing, set the RFSHE bit and SLFRF bit to 1 in REFCR. When a SLEEP instruction is executed to enter software standby mode, the $\overline{\text{CAS}}$ and $\overline{\text{RAS}}$ signals are output and DRAM enters self-refresh mode, as shown in figure 6.38.

When software standby mode is exited, the SLFRF bit is cleared to 0 and self-refresh mode is exited automatically. If a CBR refresh request occurs when making a transition to software standby mode, CBR refreshing is executed, and then self-refresh mode is entered.

When using self-refresh mode, the OPE bit must not be cleared to 0 in the SBYCR register.

Note: $n = 2, 3$

Figure 6.38 Self-Refresh Timing

In some DRAMs provided with a self-refresh mode, the $\overline{\text{RAS}}$ signal precharge time immediately after self-refreshing is longer than the normal precharge time. A setting can be made in bits TPCS2 to TPCS0 in REFCR to make the precharge time immediately after self-refreshing from 1 to 7 states longer than the normal precharge time. In this case, too, normal precharging is performed according to the setting of bits TPC1 and TPC0 in DRACCR, and therefore a setting should be made to give the optimum post-self-refresh precharge time, including this time. Figure 6.39 shows an example of the timing when the precharge time immediately after self-refreshing is extended by 2 states.

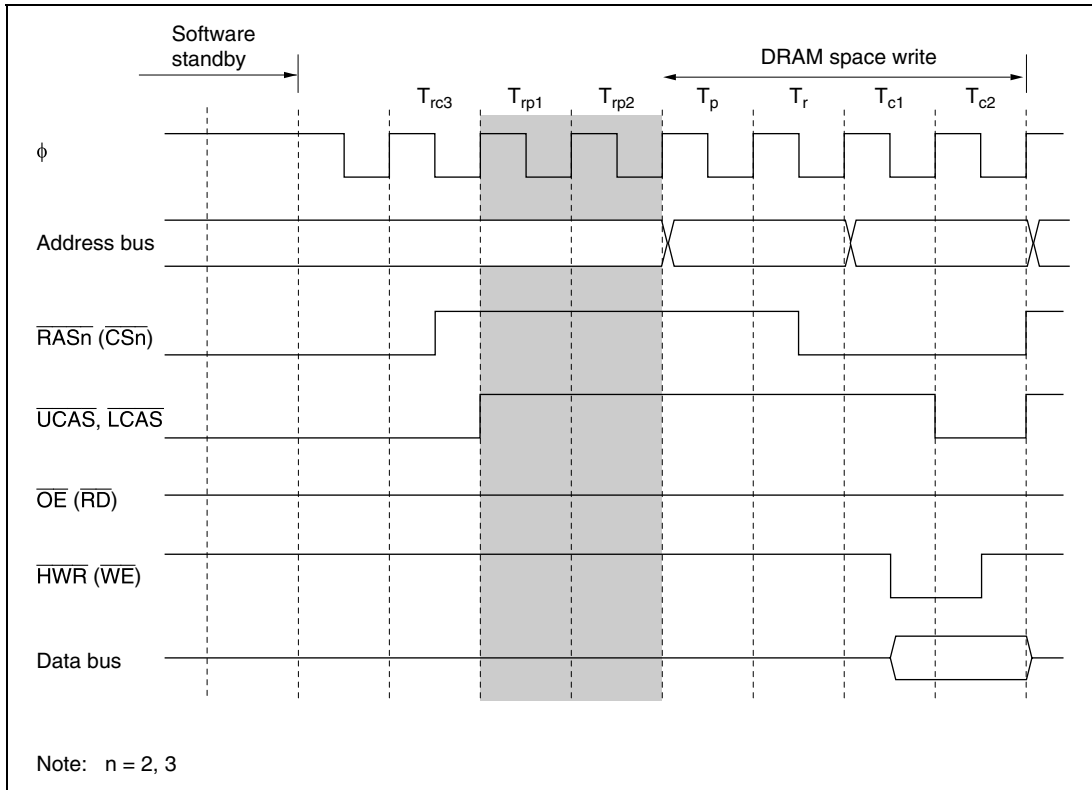

Figure 6.39 Example of Timing when Precharge Time after Self-Refreshing is Extended by 2 States

Refreshing and All-Module-Clocks-Stopped Mode: In this LSI, if the ACSE bit is set to 1 in MSTPCR_H, and then a SLEEP instruction is executed with the setting for all peripheral module clocks to be stopped (MSTPCR = H'FFFF, EXMSTPCR = H'FFFF) or for operation of the 8-bit timer module alone (MSTPCR = H'FFFE, EXMSTPCR = H'FFFF), and a transition is made to the sleep state, the all-module-clocks-stopped mode is entered, in which the bus controller and I/O port clocks are also stopped. As the bus controller clock is also stopped in this mode, CBR refreshing is not executed. If DRAM is connected externally and DRAM data is to be retained in sleep mode, the ACSE bit must be cleared to 0 in MSTPCR_H.

6.6.13 DMAC Single Address Transfer Mode and DRAM Interface

When burst mode is selected on the DRAM interface, the $\overline{\text{DACK}}$ output timing can be selected with the DDS bit in DRAMCR. When DRAM space is accessed in DMAC single address mode at the same time, these bits select whether or not burst access is to be performed.

When DDS = 1 : Burst access is performed by determining the address only, irrespective of the bus master. With the DRAM interface, the $\overline{\text{DACK}}$ output goes low from the T_{c1} state.

Figure 6.40 shows the $\overline{\text{DACK}}$ output timing for the DRAM interface when $\text{DDS} = 1$.

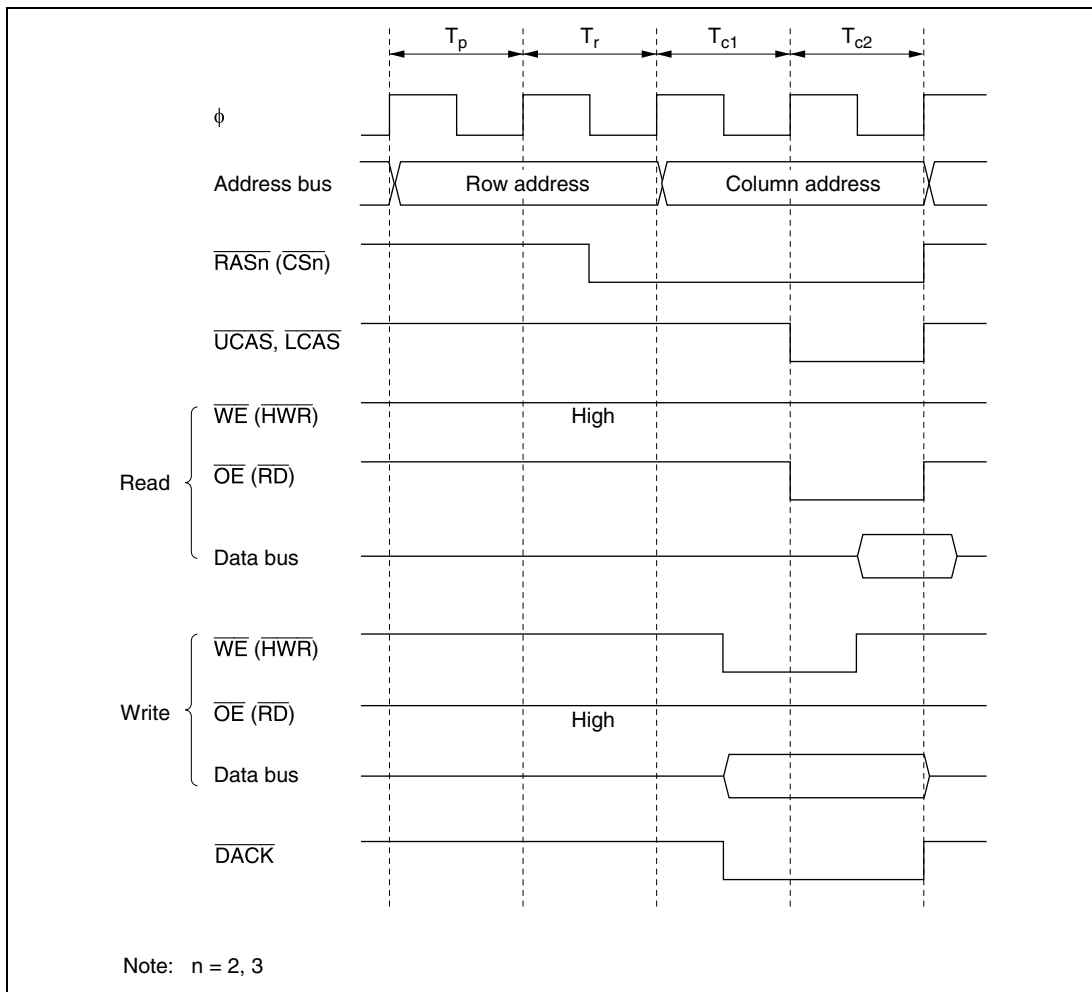

Figure 6.40 Example of $\overline{\text{DACK}}$ Output Timing when $\text{DDS} = 1$ ($\text{RAST} = 0$, $\text{CAST} = 0$)

When $\text{DDS} = 0$: When DRAM space is accessed in DMAC single address transfer mode, full access (normal access) is always performed. With the DRAM interface, the $\overline{\text{DACK}}$ output goes low from the T_r state.

In modes other than DMAC single address transfer mode, burst access can be used when accessing DRAM space.

Figure 6.41 shows the $\overline{\text{DACK}}$ output timing for the DRAM interface when $\text{DDS} = 0$.

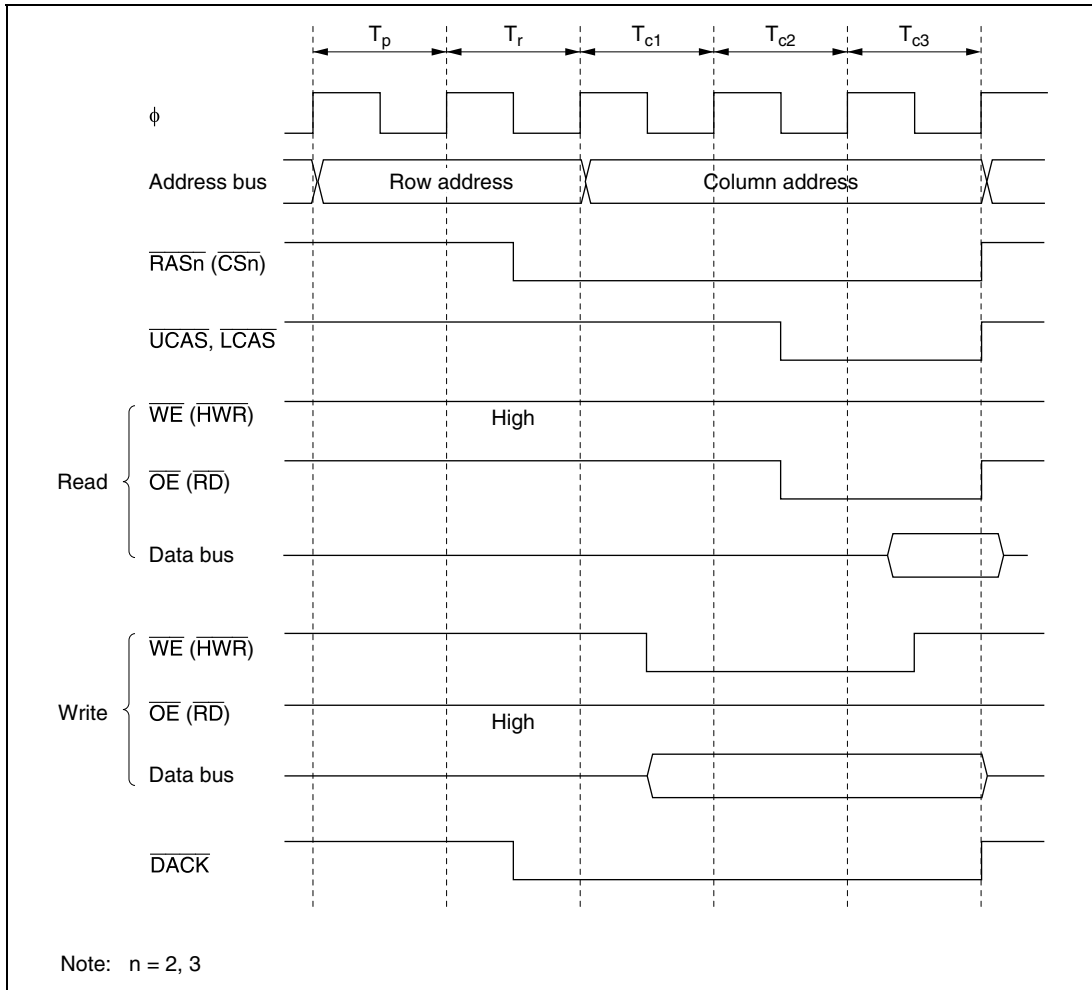

Figure 6.41 Example of $\overline{\text{DACK}}$ Output Timing when $\text{DDS} = 0$ ($\text{RAST} = 0$, $\text{CAST} = 1$)

6.7 Burst ROM Interface

In this LSI, external address space areas 0 and 1 can be designated as burst ROM space, and burst ROM interfacing performed. The burst ROM space enables ROM with burst access capability to be accessed at high speed.

Areas 1 and 0 can be designated as burst ROM space by means of bits BSRM1 and BSRM0 in BROMCR. Continuous burst accesses of 4, 8, 16, or 32 words can be performed, according to the setting of the BSWD11 and BSWD10 bits in BROMCR. From 1 to 8 states can be selected for burst access.

Settings can be made independently for area 0 and area 1.

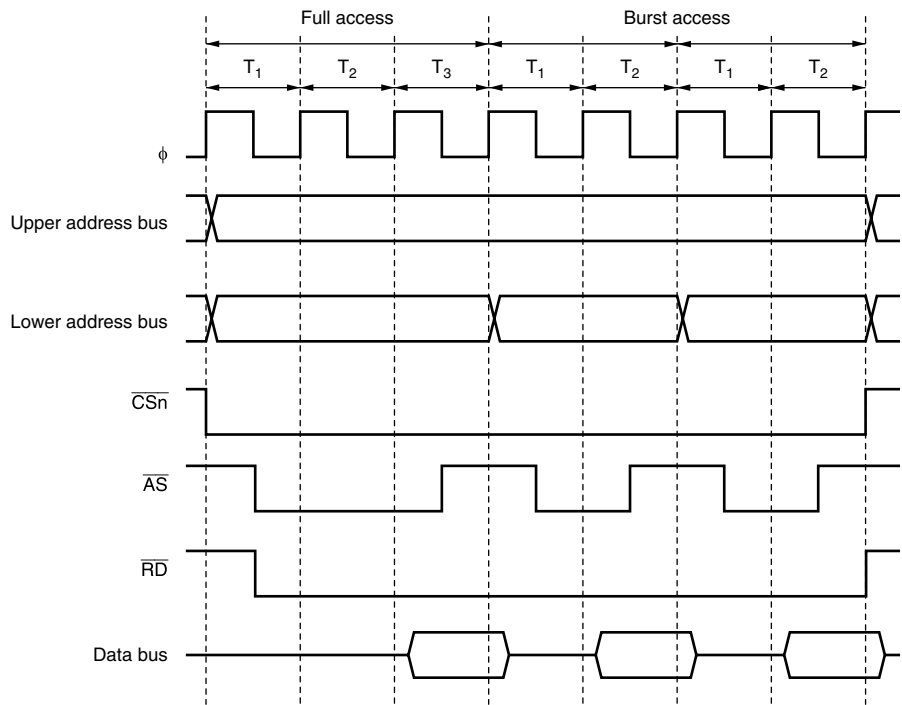

In burst ROM space, burst access covers only CPU read accesses.

6.7.1 Basic Timing

The number of access states in the initial cycle (full access) on the burst ROM interface is determined by the basic bus interface settings in ASTCR, ABWCR, WTCRA, WTCRB, and CSACRH. When area 0 or area 1 is designated as burst ROM space, the settings in RDNCR and CSACRL are ignored.

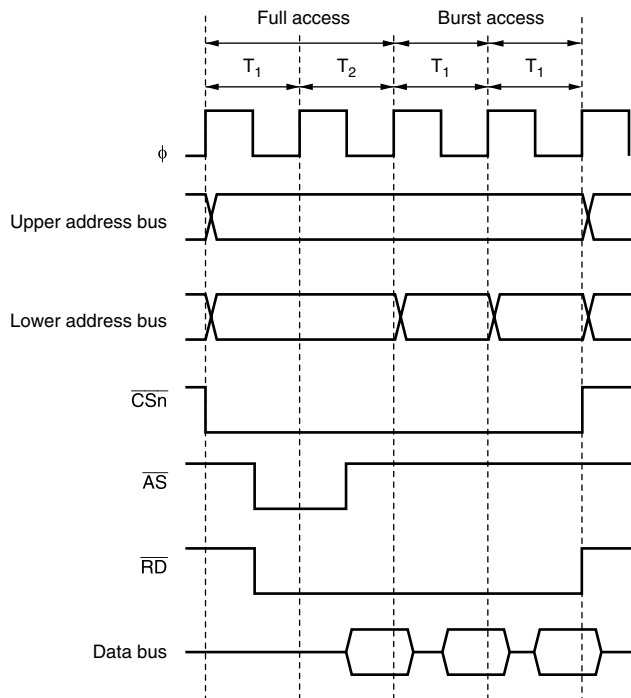

From 1 to 8 states can be selected for the burst cycle, according to the settings of bits BSTS02 to BSTS00 and BSTS12 to BSTS10 in BROMCR. Wait states cannot be inserted. Burst access of up to 32 words is performed, according to the settings of bits BSTS01, BSTS00, BSTS11, and BSTS10 in BROMCR.

The basic access timing for burst ROM space is shown in figures 6.42 and 6.43.

Note: $n = 1, 0$

Figure 6.42 Example of Burst ROM Access Timing
(ASTn = 1, 2-State Burst Cycle)

Note: $n = 1, 0$

Figure 6.43 Example of Burst ROM Access Timing
($ASTn = 0$, 1-State Burst Cycle)

6.7.2 Wait Control

As with the basic bus interface, either program wait insertion or pin wait insertion using the \overline{WAIT} pin can be used in the initial cycle (full access) on the burst ROM interface. See section 6.5.4, Wait Control. Wait states cannot be inserted in a burst cycle.

6.7.3 Write Access

When a write access to burst ROM space is executed, burst access is interrupted at that point and the write access is executed in line with the basic bus interface settings. Write accesses are not performed in burst mode even though burst ROM space is designated.

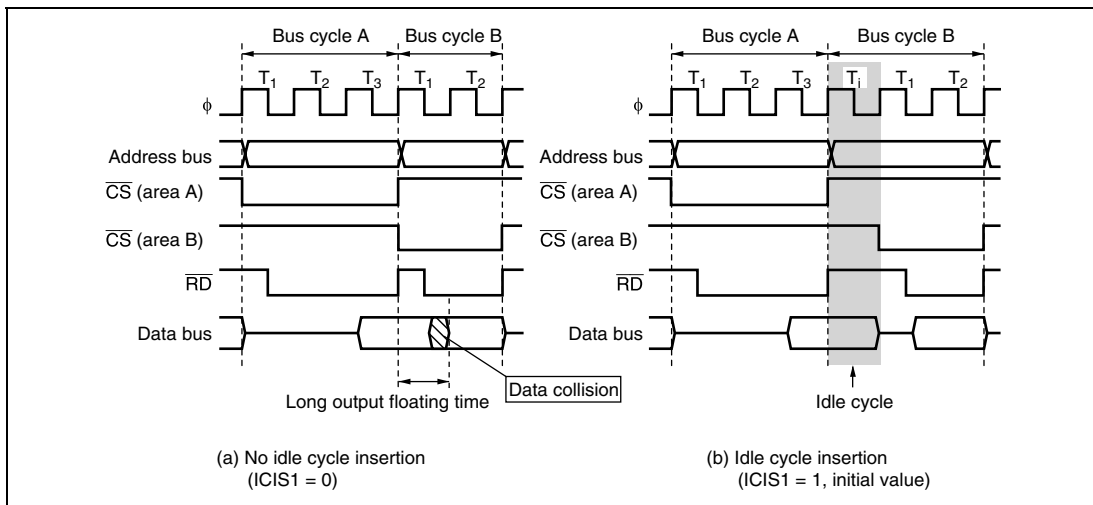

6.8 Idle Cycle

6.8.1 Operation

When this LSI accesses external address space, it can insert an idle cycle (T_i) between bus cycles in the following three cases: (1) when read accesses in different areas occur consecutively, (2) when a write cycle occurs immediately after a read cycle, and (3) when a read cycle occurs immediately after a write cycle. Insertion of a 1-state or 2-state idle cycle can be selected with the IDLC bit in BCR. By inserting an idle cycle it is possible, for example, to avoid data collisions between ROM, etc., with a long output floating time, and high-speed memory, I/O interfaces, and so on.

Consecutive Reads in Different Areas: If consecutive reads in different areas occur while the ICIS1 bit is set to 1 in BCR, an idle cycle is inserted at the start of the second read cycle.

Figure 6.44 shows an example of the operation in this case. In this example, bus cycle A is a read cycle for ROM with a long output floating time, and bus cycle B is a read cycle for SRAM, each being located in a different area. In (a), an idle cycle is not inserted, and a collision occurs in bus cycle B between the read data from ROM and that from SRAM. In (b), an idle cycle is inserted, and a data collision is prevented.

**Figure 6.44 Example of Idle Cycle Operation
(Consecutive Reads in Different Areas)**

Write after Read: If an external write occurs after an external read while the ICIS0 bit is set to 1 in BCR, an idle cycle is inserted at the start of the write cycle.

Figure 6.45 shows an example of the operation in this case. In this example, bus cycle A is a read cycle for ROM with a long output floating time, and bus cycle B is a CPU write cycle. In (a), an idle cycle is not inserted, and a collision occurs in bus cycle B between the read data from ROM and the CPU write data. In (b), an idle cycle is inserted, and a data collision is prevented.

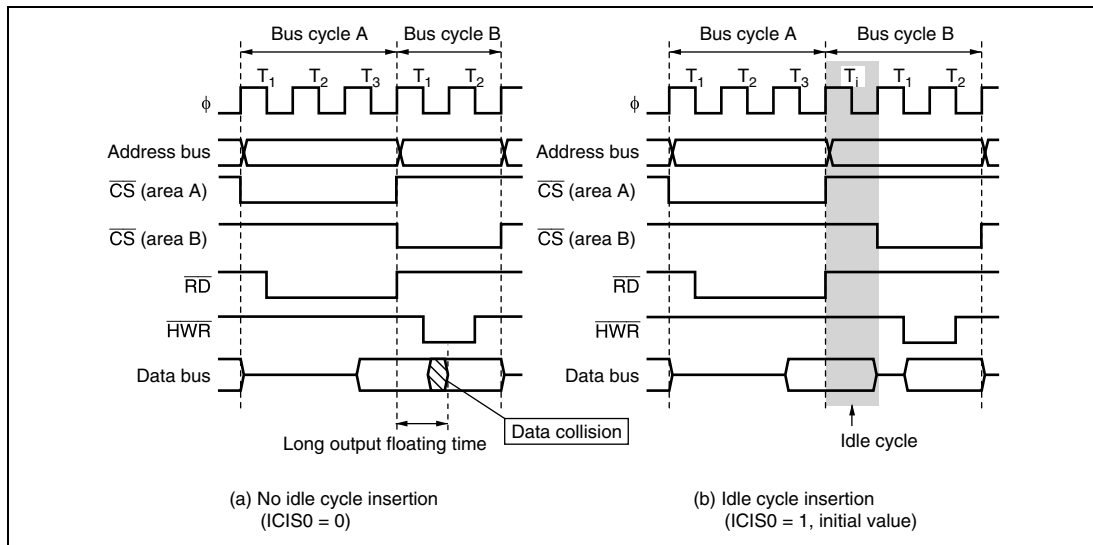

Figure 6.45 Example of Idle Cycle Operation (Write after Read)

Read after Write: If an external read occurs after an external write while the ICIS2 bit is set to 1 in BCR, an idle cycle is inserted at the start of the read cycle.

Figure 6.46 shows an example of the operation in this case. In this example, bus cycle A is a CPU write cycle and bus cycle B is a read cycle from an external device. In (a), an idle cycle is not inserted, and a collision occurs in bus cycle B between the CPU write data and read data from an external device. In (b), an idle cycle is inserted, and a data collision is prevented.

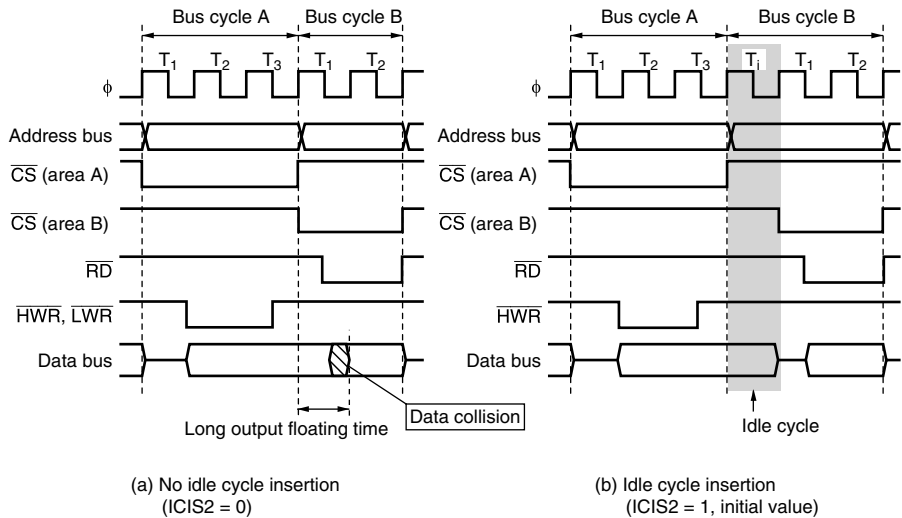

Figure 6.46 Example of Idle Cycle Operation (Read after Write)

Relationship between Chip Select (\overline{CS}) Signal and Read (\overline{RD}) Signal: Depending on the system's load conditions, the \overline{RD} signal may lag behind the \overline{CS} signal. An example is shown in figure 6.47. In this case, with the setting for no idle cycle insertion (a), there may be a period of overlap between the bus cycle A \overline{RD} signal and the bus cycle B \overline{CS} signal. Setting idle cycle insertion, as in (b), however, will prevent any overlap between the \overline{RD} and \overline{CS} signals. In the initial state after reset release, idle cycle insertion (b) is set.

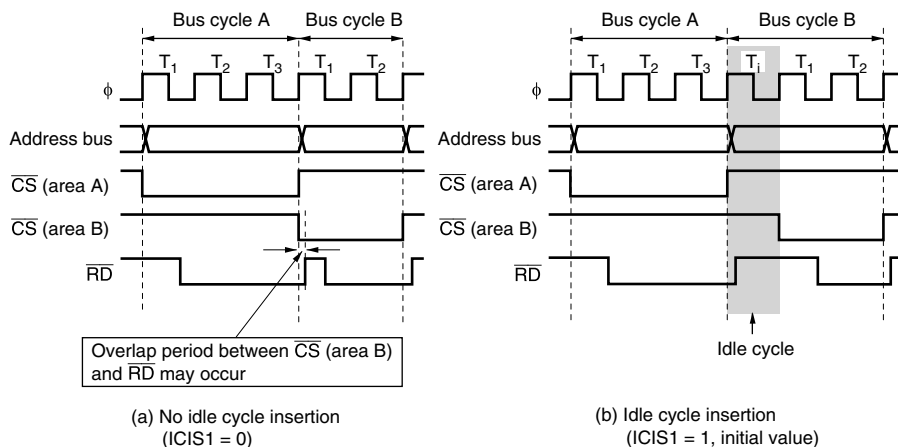

Figure 6.47 Relationship between Chip Select (\overline{CS}) and Read (\overline{RD})

Idle Cycle in Case of DRAM Space Access after Normal Space Access: In a DRAM space access following a normal space access, the settings of bits ICIS2, ICIS1, ICIS0, and IDLC in BCR are valid. However, in the case of consecutive reads in different areas, for example, if the second read is a full access to DRAM space, only a T_p cycle is inserted, and a T_i cycle is not. The timing in this case is shown in figure 6.48.

Note: The DRAM interface is not supported by the H8S/2366.

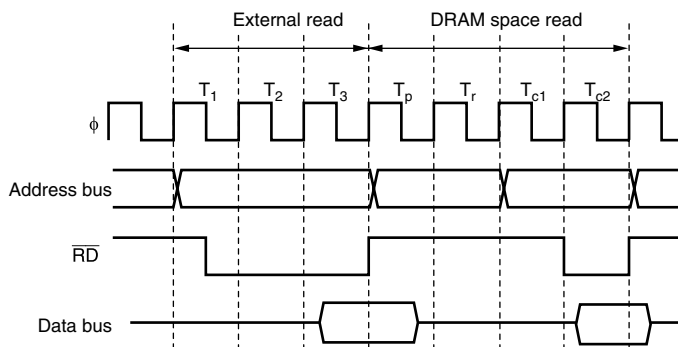

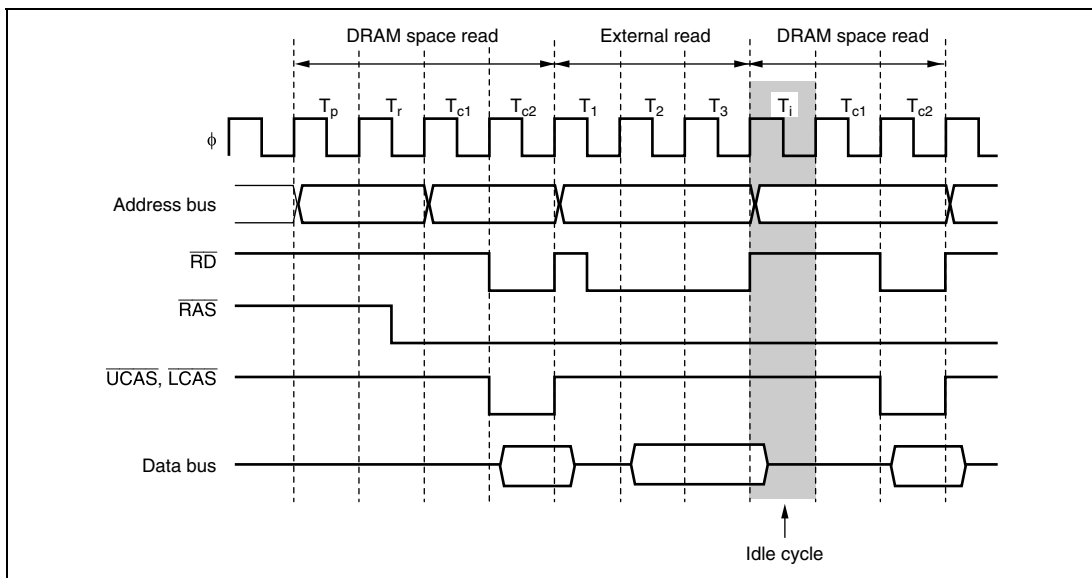

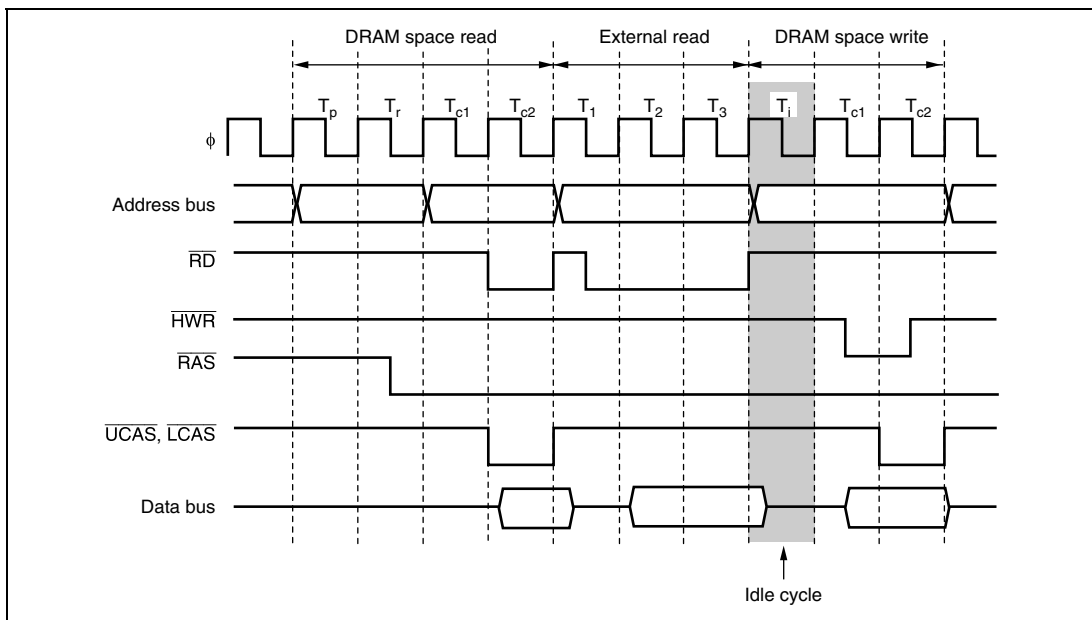

Figure 6.48 Example of DRAM Full Access after External Read (CAST = 0)

In burst access in RAS down mode, the settings of bits ICIS2, ICIS1, ICIS0, and IDLC are valid and an idle cycle is inserted. The timing in this case is illustrated in figures 6.49 and 6.50.

**Figure 6.49 Example of Idle Cycle Operation in RAS Down Mode
(Consecutive Reads in Different Areas) (IDLC = 0, RAST = 0, CAST = 0)**

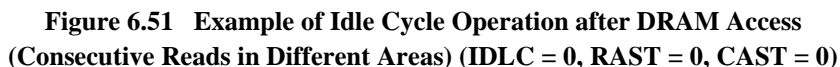

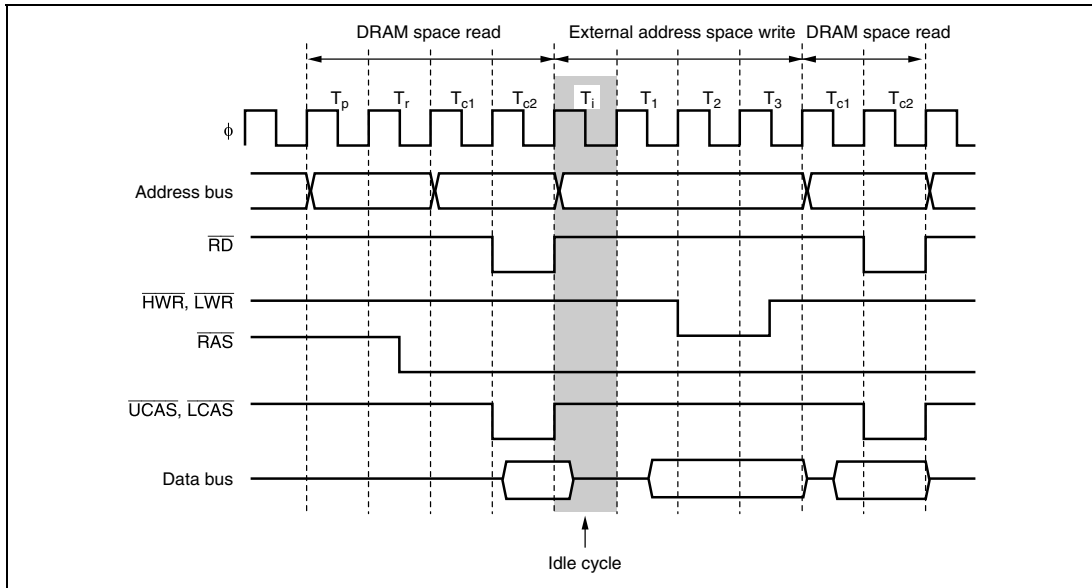

**Figure 6.50 Example of Idle Cycle Operation in RAS Down Mode
(Write after Read) (IDLC = 0, RAST = 0, CAST = 0)**

- Normal space access after DRAM space read access

When the DRMI bit is cleared to 0, an idle cycle is not inserted after DRAM space access even if bits ICIS1 and ICIS0 are set to 1.

Note: The DRAM interface is not supported by the H8S/2366.

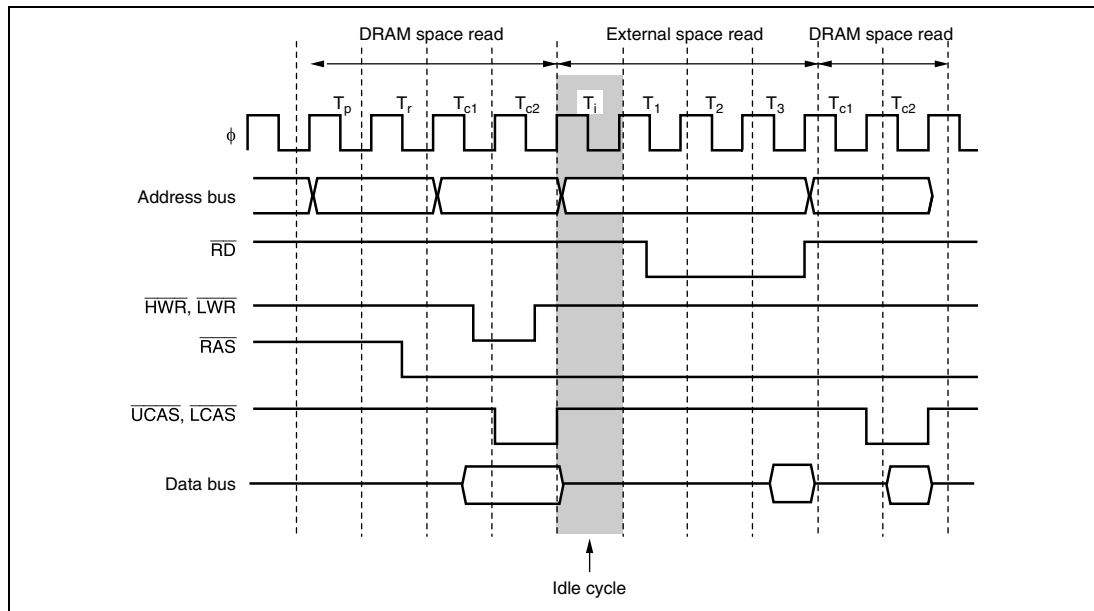

**Figure 6.52 Example of Idle Cycle Operation after DRAM Access
(Write after Read) (IDLC = 0, RAST = 0, CAST = 0)**

- Normal space access after DRAM space write access

While the ICIS2 bit is set to 1 in BCR and a normal space read access occurs after DRAM space write access, idle cycle is inserted in the first read cycle. The number of states of the idle cycle to be inserted is in accordance with the setting of the IDLC bit. It does not depend on the DRMI bit in DRACCR. Figure 6.53 shows an example of idle cycle operation when the ICIS2 bit is set to 1.

Note: The DRAM interface is not supported by the H8S/2366.

**Figure 6.53 Example of Idle Cycle Operation after DRAM Write Access
(IDLC = 0, ICIS1 = 0, RAST = 0, CAST = 0)**

Table 6.7 shows whether an idle cycle is inserted or not in mixed access to normal space and DRAM.

Table 6.7 Idle Cycles in Mixed Accesses to Normal Space and DRAM

Previous Access	Next Access	ICIS2	ICIS1	ICIS0	DRMI	IDLK	Idle cycle
Normal space read	Normal space read (different area)	—	0	—	—	—	Disabled
		—	1	—	—	0	1 state inserted
						1	2 states inserted
	DRAM/ space read	—	0	—	—	—	Disabled
		—	1	—	—	0	1 state inserted
						1	2 states inserted
	Normal space write	—	—	0	—	—	Disabled
		—	—	1	—	0	1 state inserted
						1	2 states inserted
	DRAM/ space write	—	—	0	—	—	Disabled
		—	—	1	—	0	1 state inserted
						1	2 states inserted
DRAM/ space read	Normal space read	—	0	—	—	—	Disabled
		—	1	—	0	—	Disabled
					1	0	1 state inserted
						1	2 states inserted
	DRAM/ space read	—	0	—	—	—	Disabled
		—	1	—	0	—	Disabled
					1	0	1 state inserted
						1	2 states inserted
	Normal space write	—	—	0	—	—	Disabled
		—	—	1	0	—	Disabled
					1	0	1 state inserted
						1	2 states inserted
	DRAM/ space write	—	—	0	—	—	Disabled
		—	—	1	0	—	Disabled
					1	0	1 state inserted
						1	2 states inserted

Previous Access	Next Access	ICIS2	ICIS1	ICIS0	DRMI	IDLC	Idle cycle
Normal space write	Normal space read	0	—	—	—	—	Disabled
		1	—	—	—	0	1 state inserted
						1	2 states inserted
	DRAM/ space read	0	—	—	—	—	Disabled
		1	—	—	—	0	1 state inserted
						1	2 states inserted
DRAM/ space write	Normal space read	0	—	—	—	—	Disabled
		1	—	—	—	0	1 state inserted
						1	2 states inserted
	DRAM/ space read	0	—	—	—	—	Disabled
		1	—	—	—	0	1 state inserted
						1	2 states inserted

Setting the DRMI bit in DRACCR to 1 enables an idle cycle to be inserted in the case of consecutive read and write operations in DRAM/ space burst access. Figures 6.54 shows an example of the timing for idle cycle insertion in the case of consecutive read and write accesses to DRAM/continuous synchronous DRAM space.

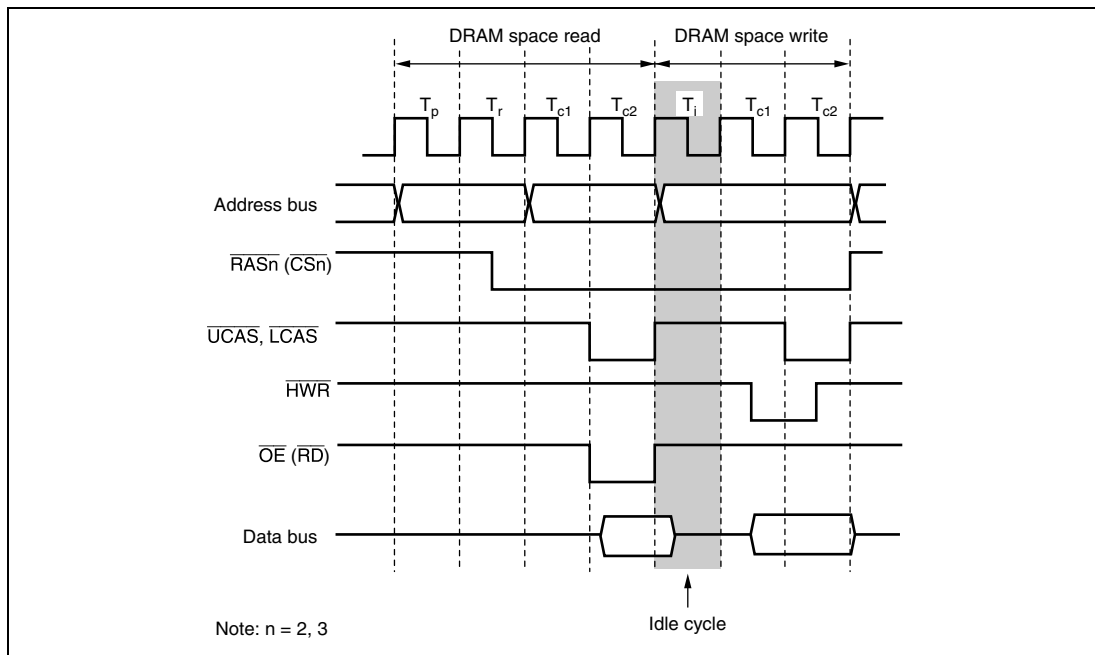

Figure 6.54 Example of Timing for Idle Cycle Insertion in Case of Consecutive Read and Write Accesses to DRAM Space in RAS Down Mode

6.8.2 Pin States in Idle Cycle

Table 6.8 shows the pin states in an idle cycle.

Table 6.8 Pin States in Idle Cycle

Pins	Pin State
A23 to A0	Contents of following bus cycle
D15 to D0	High impedance
\overline{CSn} (n = 7 to 0)	High* ¹ * ²
\overline{UCAS}^{*3} , \overline{LCAS}^{*3}	High* ²
\overline{AS}	High
\overline{RD}	High
\overline{OE}	High
\overline{HWR} , \overline{LWR}	High
\overline{DACKn}^{*3} (n = 1, 0)	High

Notes: *1 Remains low in DRAM space RAS down mode.

*2 Remains low in a DRAM space refresh cycle.

*3 Not supported by the H8S/2366.

6.9 Write Data Buffer Function

This LSI has a write data buffer function for the external data bus. Using the write data buffer function enables external writes and DMA single address mode transfers* to be executed in parallel with internal accesses. The write data buffer function is made available by setting the WDBE bit to 1 in BCR.

Figure 6.55 shows an example of the timing when the write data buffer function is used. When this function is used, if an external address space write or DMA single address mode transfer* continues for two states or longer, and there is an internal access next, an external write only is executed in the first state, but from the next state onward an internal access (on-chip memory or internal I/O register read/write) is executed in parallel with the external address space write rather than waiting until it ends.

Note: * Not supported by the H8S/2366.

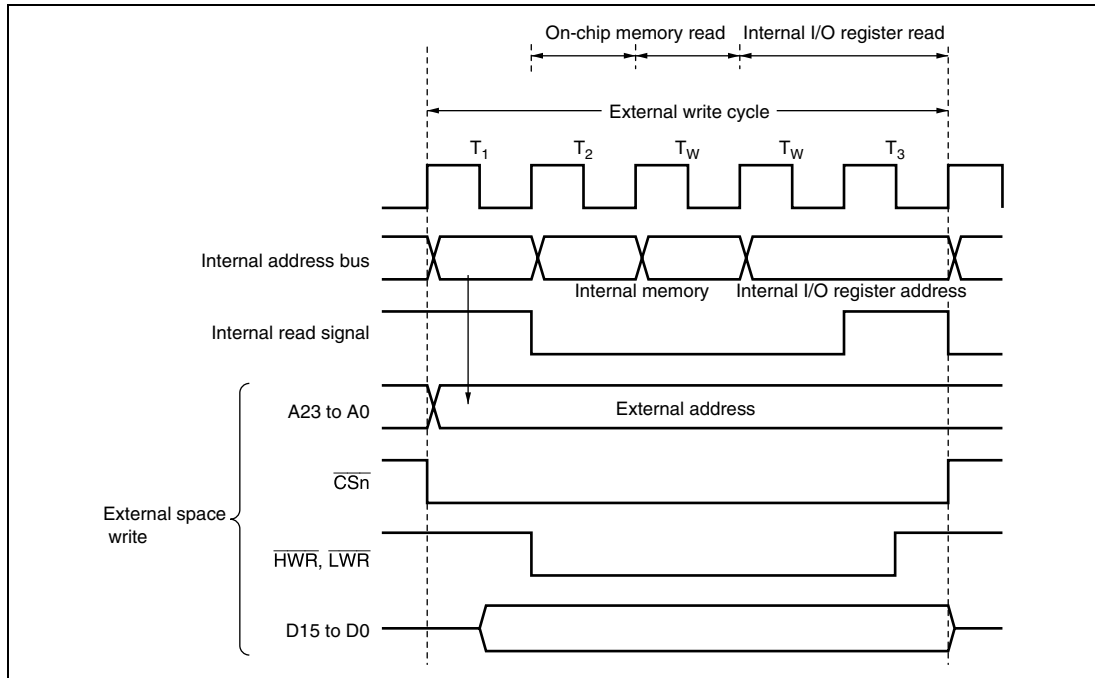

Figure 6.55 Example of Timing when Write Data Buffer Function is Used

6.10 Bus Release

This LSI can release the external bus in response to a bus request from an external device. In the external bus released state, internal bus masters continue to operate as long as there is no external access. If any of the following requests are issued in the external bus released state, the $\overline{\text{BREQO}}$ signal can be driven low to output a bus request externally.

- When an internal bus master wants to perform an external access
- When a refresh request is generated
- When a SLEEP instruction is executed to place the chip in software standby mode or all-module-clocks-stopped mode

6.10.1 Operation

In externally expanded mode, the bus can be released to an external device by setting the BRLE bit to 1 in BCR. Driving the $\overline{\text{BREQ}}$ pin low issues an external bus request to this LSI. When the $\overline{\text{BREQ}}$ pin is sampled, at the prescribed timing the $\overline{\text{BACK}}$ pin is driven low, and the address bus, data bus, and bus control signals are placed in the high-impedance state, establishing the external bus released state.

In the external bus released state, internal bus masters can perform accesses using the internal bus. When an internal bus master wants to make an external access, it temporarily defers initiation of the bus cycle, and waits for the bus request from the external bus master to be canceled. If a refresh request is generated in the external bus released state, or if a SLEEP instruction is executed to place the chip in software standby mode or all-module-clocks-stopped mode, refresh control and software standby or all-module-clocks-stopped control is deferred until the bus request from the external bus master is canceled.

If the BREQOE bit is set to 1 in BCR, the $\overline{\text{BREQO}}$ pin can be driven low when any of the following requests are issued, to request cancellation of the bus request externally.

- When an internal bus master wants to perform an external access
- When a refresh request is generated
- When a SLEEP instruction is executed to place the chip in software standby mode or all-module-clocks-stopped mode

When the $\overline{\text{BREQ}}$ pin is driven high, the $\overline{\text{BACK}}$ pin is driven high at the prescribed timing and the external bus released state is terminated.

If an external bus release request and external access occur simultaneously, the order of priority is as follows:

(High) External bus release > External access by internal bus master (Low)

If a refresh request and external bus release request occur simultaneously, the order of priority is as follows:

(High) Refresh > External bus release (Low)

6.10.2 Pin States in External Bus Released State

Table 6.9 shows pin states in the external bus released state.

Table 6.9 Pin States in Bus Released State

Pins	Pin State
A23 to A0	High impedance
D15 to D0	High impedance
$\overline{\text{CS}}_n$ (n = 7 to 0)	High impedance
$\overline{\text{UCAS}}^*$, $\overline{\text{LCAS}}^*$	High impedance
$\overline{\text{AS}}$	High impedance
$\overline{\text{RD}}$	High impedance
$\overline{\text{OE}}$	High impedance
$\overline{\text{HWR}}$, $\overline{\text{LWR}}$	High impedance
$\overline{\text{DACK}}_n^*$ (n = 1, 0)	High

Note: * Not supported by the H8S/2366.

6.10.3 Transition Timing

Figure 6.56 shows the timing for transition to the bus released state.

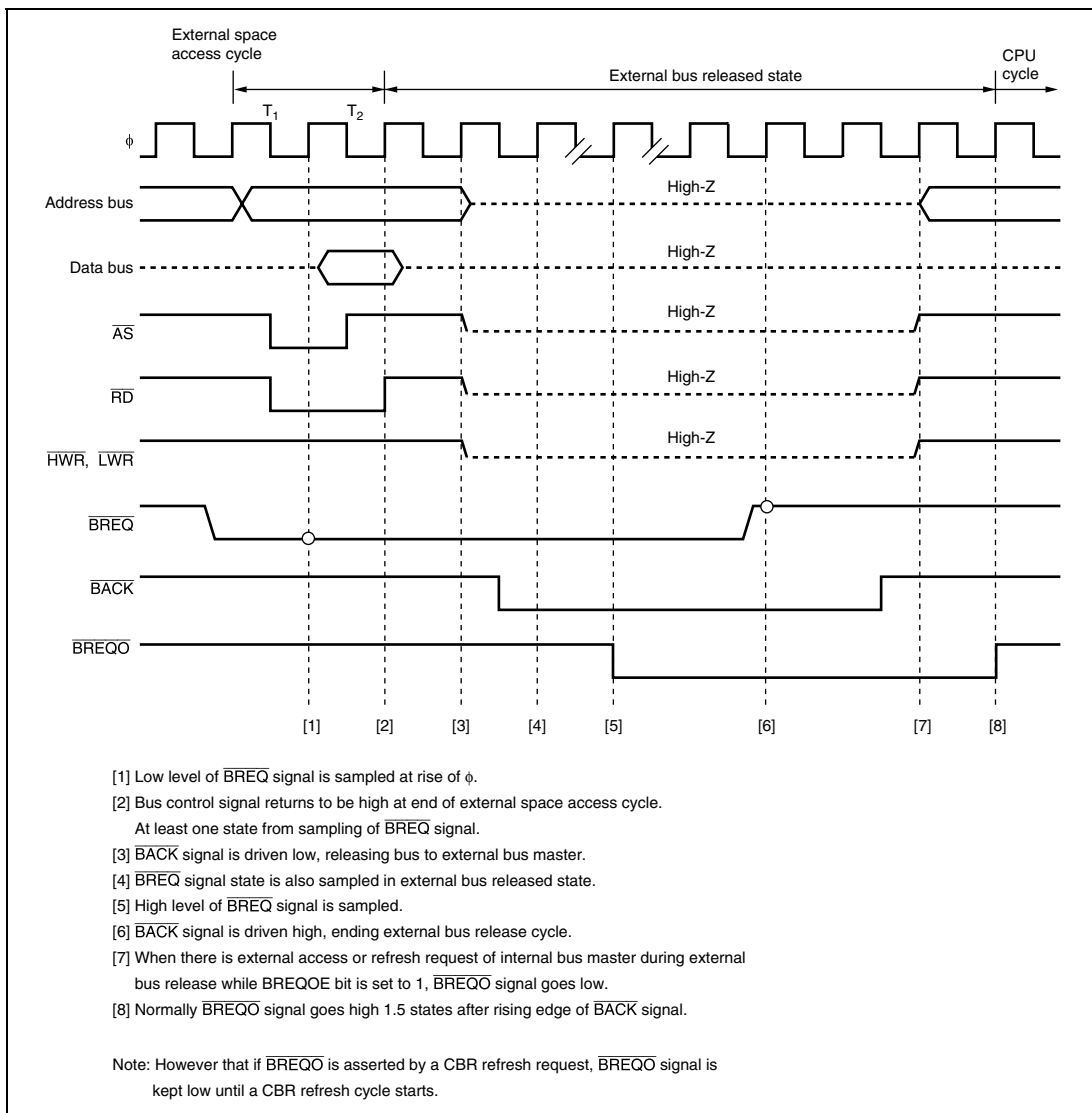

Figure 6.56 Bus Released State Transition Timing

6.11 Bus Arbitration

This LSI has a bus arbiter that arbitrates bus master operations (bus arbitration).

There are three bus masters—the CPU, DTC, and DMAC*—which perform read/write operations when they have possession of the bus. Each bus master requests the bus by means of a bus request signal. The bus arbiter determines priorities at the prescribed timing, and permits use of the bus by means of a bus request acknowledge signal. The selected bus master then takes possession of the bus and begins its operation.

Note: * Not supported by the H8S/2366.

6.11.1 Operation

The bus arbiter detects the bus masters' bus request signals, and if the bus is requested, sends a bus request acknowledge signal to the bus master. If there are bus requests from more than one bus master, the bus request acknowledge signal is sent to the one with the highest priority. When a bus master receives the bus request acknowledge signal, it takes possession of the bus until that signal is canceled.

The order of priority of the bus masters is as follows:

(High) DMAC* > DTC > CPU (Low)

An internal bus access by internal bus masters and external bus release, a refresh when the CBRM bit is 0 can be executed in parallel.

If an external bus release request, a refresh request, and an external access by an internal bus master occur simultaneously, the order of priority is as follows:

(High) Refresh > External bus release (Low)

(High) External bus release > External access by internal bus master (Low)

As a refresh when the CBRM bit in REFCR is cleared to 0 and an external access other than to DRAM space by an internal bus master can be executed simultaneously, there is no relative order of priority for these two operations.

Note: * Not supported by the H8S/2366.

6.11.2 Bus Transfer Timing

Even if a bus request is received from a bus master with a higher priority than that of the bus master that has acquired the bus and is currently operating, the bus is not necessarily transferred immediately. There are specific timings at which each bus master can relinquish the bus.

CPU: The CPU is the lowest-priority bus master, and if a bus request is received from the DTC, or DMAC*, the bus arbiter transfers the bus to the bus master that issued the request. The timing for transfer of the bus is as follows:

- The bus is transferred at a break between bus cycles. However, if a bus cycle is executed in discrete operations, as in the case of a longword-size access, the bus is not transferred between the component operations.
- With bit manipulation instructions such as BSET and BCLR, the sequence of operations is: data read (read), relevant bit manipulation operation (modify), write-back (write). The bus is not transferred during this read-modify-write cycle, which is executed as a series of bus cycles.
- If the CPU is in sleep mode, the bus is transferred immediately.

Note: * Not supported by the H8S/2366.

DTC: The DTC sends the bus arbiter a request for the bus when an activation request is generated.

The DTC can release the bus after a vector read, a register information read (3 states), a single data transfer, or a register information write (3 states). It does not release the bus during a register information read (3 states), a single data transfer, or a register information write (3 states).

DMAC: The DMAC sends the bus arbiter a request for the bus when an activation request is generated.

In the case of an external request in short address mode or normal mode, and in cycle steal mode, the DMAC releases the bus after a single transfer.

In block transfer mode, it releases the bus after transfer of one block, and in burst mode, after completion of the transfer. However, in the event of external bus release request, which have a higher priority than the DMAC, the bus may be transferred to the bus master even if block or burst transfer is in progress.

Note: Not supported by the H8S/2366.

External Bus Release: When the $\overline{\text{BREQ}}$ pin goes low and an external bus release request is issued while the BRLE bit is set to 1 in BCR, a bus request is sent to the bus arbiter.

External bus release can be performed on completion of an external bus cycle.

6.12 Bus Controller Operation in Reset

In a reset, this LSI, including the bus controller, enters the reset state immediately, and any executing bus cycle is aborted.

6.13 Usage Notes

6.13.1 External Bus Release Function and All-Module-Clocks-Stopped Mode

In this LSI, if the ACSE bit is set to 1 in MSTPCR, and then a SLEEP instruction is executed with the setting for all peripheral module clocks to be stopped (MSTPCR = H'FFFF, EXMSTPCR = H'FFFF) or for operation of the 8-bit timer module alone (MSTPCR = H'FFFE, EXMSTPCR = H'FFFF), and a transition is made to the sleep state, the all-module-clocks-stopped mode is entered in which the clock is also stopped for the bus controller and I/O ports. In this state, the external bus release function is halted. To use the external bus release function in sleep mode, the ACSE bit in MSTPCR must be cleared to 0. Conversely, if a SLEEP instruction to place the chip in all-module-clocks-stopped mode is executed in the external bus released state, the transition to all-module-clocks-stopped mode is deferred and performed until after the bus is recovered.

6.13.2 External Bus Release Function and Software Standby

In this LSI, internal bus master operation does not stop even while the bus is released, as long as the program is running in on-chip ROM, etc., and no external access occurs. If a SLEEP instruction to place the chip in software standby mode is executed while the external bus is released, the transition to software standby mode is deferred and performed after the bus is recovered.

Also, since clock oscillation halts in software standby mode, if $\overline{\text{BREQ}}$ goes low in this mode, indicating an external bus release request, the request cannot be answered until the chip has recovered from the software standby state.

6.13.3 External Bus Release Function and CBR Refreshing

CBR refreshing cannot be executed while the external bus is released. Setting the BREQOE bit to 1 in BCR beforehand enables the $\overline{\text{BREQO}}$ signal to be output when a CBR refresh request is issued.

Note: Not supported by the H8S/2366.

6.13.4 $\overline{\text{BREQO}}$ Output Timing

When the BREQOE bit is set to 1 and the $\overline{\text{BREQO}}$ signal is output, $\overline{\text{BREQO}}$ may go low before the $\overline{\text{BACK}}$ signal.

This will occur if the next external access request or CBR refresh request occurs while internal bus arbitration is in progress after the chip samples a low level of $\overline{\text{BREQ}}$.

Section 7 DMA Controller (DMAC)

This LSI has a built-in DMA controller (DMAC) which can carry out data transfer on up to 4 channels.

Note: Not supported by the H8S/2366.

7.1 Features

- Choice of short address mode or full address mode
 - Short address mode
 - Maximum of 4 channels can be used
 - Dual address mode or single address mode can be selected
 - In dual address mode, one of the two addresses, transfer source and transfer destination, is specified as 24 bits and the other as 16 bits
 - In single address mode, transfer source or transfer destination address only is specified as 24 bits
 - In single address mode, transfer can be performed in one bus cycle
 - Choice of sequential mode, idle mode, or repeat mode for dual address mode and single address mode
 - Full address mode
 - Maximum of 2 channels can be used
 - Transfer source and transfer destination addresses as specified as 24 bits
 - Choice of normal mode or block transfer mode
- 16-Mbyte address space can be specified directly
- Byte or word can be set as the transfer unit
- Activation sources: internal interrupt, external request, auto-request (depending on transfer mode)
 - Six 16-bit timer-pulse unit (TPU) compare match/input capture interrupts
 - Serial communication interface (SCI_0, SCI_1) transmission complete interrupt, reception complete interrupt
 - A/D converter conversion end interrupt
 - External request
 - Auto-request
- Module stop mode can be set

A block diagram of the DMAC is shown in figure 7.1.

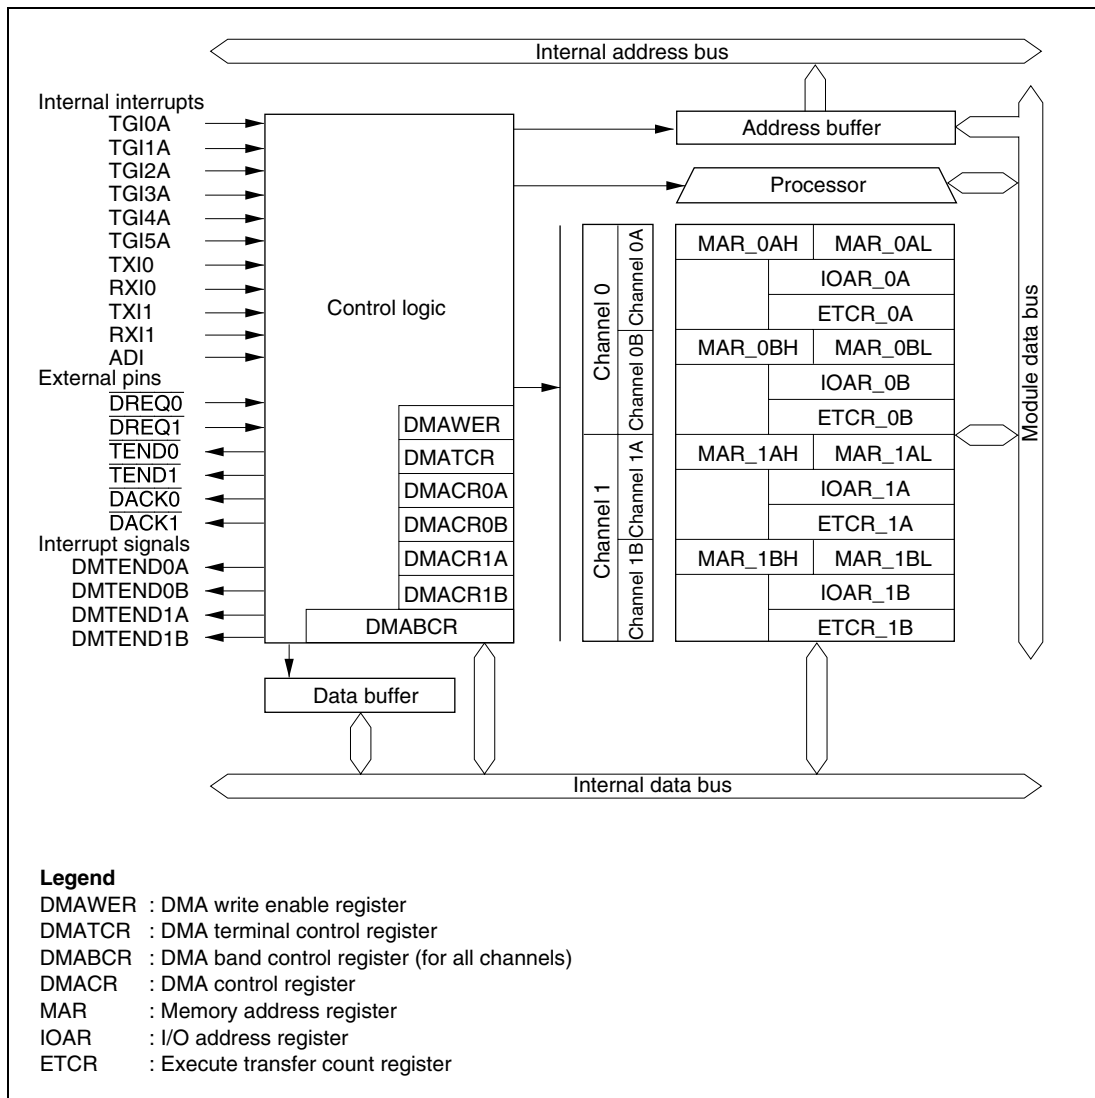

Figure 7.1 Block Diagram of DMAC

7.2 Input/Output Pins

Table 7.1 summarizes the pins of the interrupt controller.

Table 7.1 Pin Configuration

Channel	Pin Name	Symbol	I/O	Function
0	DMA request 0	$\overline{\text{DREQ0}}$	Input	Channel 0 external request
	DMA transfer acknowledge 0	$\overline{\text{DACK0}}$	Output	Channel 0 single address transfer acknowledge
	DMA transfer end 0	$\overline{\text{TEND0}}$	Output	Channel 0 transfer end
1	DMA request 1	$\overline{\text{DREQ1}}$	Input	Channel 1 external request
	DMA transfer acknowledge 1	$\overline{\text{DACK1}}$	Output	Channel 1 single address transfer acknowledge
	DMA transfer end 1	$\overline{\text{TEND1}}$	Output	Channel 1 transfer end

7.3 Register Descriptions

- Memory address register_0AH (MAR_0AH)
- Memory address register_0AL (MAR_0AL)
- I/O address register_0A (IOAR_0A)
- Transfer count register_0A (ECTR_0A)
- Memory address register_0BH (MAR_0BH)
- Memory address register_0BL (MAR_0BL)
- I/O address register_0B (IOAR_0B)
- Transfer count register_0B (ECTR_0B)
- Memory address register_1AH (MAR_1AH)
- Memory address register_1AL (MAR_1AL)
- I/O address register_1A (IOAR_1A)
- Transfer count register_1A (ETCR_1B)
- Memory address register_1BH (MAR_1BH)
- Memory address register_1BL (MAR_1BL)
- I/O address register_1B (IOAR_1B)
- Transfer count register_1B (ETCR_1B)
- DMA control register_0A (DMACR_0A)
- DMA control register_0B (DMACR_0B)
- DMA control register_1A (DMACR_1A)
- DMA control register_1B (DMACR_1B)

- DMA band control register H (DMABCRH)
- DMA band control register L (DMABCR L)
- DMA write enable register (DMAWER)
- DMA terminal control register (DMATCR)

The functions of MAR, IOAR, ETCR, DMACR, and DMABCR differ according to the transfer mode (short address mode or full address mode). The transfer mode can be selected by means of the FAE1 and FAE0 bits in DMABCRH. The register configurations for short address mode and full address mode of channel 0 are shown in table 7.2.

Table 7.2 Short Address Mode and Full Address Mode (Channel 0)

FAE0	Description	
0	Short address mode specified (channels 0A and 0B operate independently)	
Channel 0A	MAR_0AH	← Specifies transfer source/transfer destination address
	MAR_0AL	← Specifies transfer destination/transfer source address
	IOAR_0A	← Specifies number of transfers
	ETCR_0A	← Specifies transfer size, mode, activation source
Channel 0B	MAR_0BH	← Specifies transfer source/transfer destination address
	MAR_0BL	← Specifies transfer destination/transfer source address
	IOAR_0B	← Specifies number of transfers
	ETCR_0B	← Specifies transfer size, mode, activation source
1	Full address mode specified (channels 0A and 0B operate in combination as channel 0)	
Channel 0	MAR_0AH	← Specifies transfer source address
	MAR_0AL	← Specifies transfer destination address
	MAR_0BH	← Not used
	MAR_0BL	← Not used
	IOAR_0A	← Specifies number of transfers
	IOAR_0B	← Specifies number of transfers (used in block transfer mode only)
	ETCR_0A	← Specifies transfer size, mode, activation source, etc.
	ETCR_0B	
Channel 0	DMACR_0A	
	DMACR_0B	

7.3.1 Memory Address Registers (MARA and MARB)

MAR is a 32-bit readable/writable register that specifies the source address (transfer source address) or destination address (transfer destination address). MAR consists of two 16-bit registers MARH and MARL. The upper 8 bits of MARH are reserved: they are always read as 0, and cannot be modified.

The DMA has four MAR registers: MAR_0A in channel 0 (channel 0A), MAR_0B in channel 0 (channel 0B), MAR_1A in channel 1 (channel 1A), and MAR_1B in channel 1 (channel 1B).

MAR is not initialized by a reset or in standby mode.

Short Address Mode: In short address mode, MARA and MARB operate independently. Whether MAR functions as the source address register or as the destination address register can be selected by means of the DTDIR bit in DMACR.

MAR is incremented or decremented each time a byte or word transfer is executed, so that the address specified by MAR is constantly updated.

Full Address Mode: In full address mode, MARA functions as the source address register, and MARB as the destination address register.

MAR is incremented or decremented each time a byte or word transfer is executed, so that the source or destination address is constantly updated.

7.3.2 I/O Address Registers (IOARA and IOARB)

IOAR is a 16-bit readable/writable register that specifies the lower 16 bits of the source address (transfer source address) or destination address (transfer destination address). The upper 8 bits of the transfer address are automatically set to H'FF.

The DMA has four IOAR registers: IOAR_0A in channel 0 (channel 0A), IOAR_0B in channel 0 (channel 0B), IOAR_1A in channel 1 (channel 1A), and IOAR_1B in channel 1 (channel 1B).

Whether IOAR functions as the source address register or as the destination address register can be selected by means of the DTDIR bit in DMACR.

IOAR is not incremented or decremented each time a data transfer is executed, so the address specified by IOAR is fixed.

IOAR is not initialized by a reset or in standby mode.

IOAR can be used in short address mode but not in full address mode.

7.3.3 Execute Transfer Count Registers (ETCRA and ETCRB)

ETCR is a 16-bit readable/writable register that specifies the number of transfers.

The DMA has four ETCR registers: ETCR_0A in channel 0 (channel 0A), ETCR_0B in channel 0 (channel 0B), ETCR_1A in channel 1 (channel 1A), and ETCR_1B in channel 1 (channel 1B).

ETCR is not initialized by a reset or in standby mode.

Short Address Mode: The function of ETCR in sequential mode and idle mode differs from that in repeat mode.

In sequential mode and idle mode, ETCR functions as a 16-bit transfer counter. ETCR is decremented by 1 each time a transfer is performed, and when the count reaches H'00, the DTE bit in DMABCRL is cleared, and transfer ends.

In repeat mode, ETCRL functions as an 8-bit transfer counter and ETCRH functions as a transfer count holding register. ETCRL is decremented by 1 each time a transfer is performed, and when the count reaches H'00, ETCRL is loaded with the value in ETCRH. At this point, MAR is automatically restored to the value it had when the count was started. The DTE bit in DMABCRL is not cleared, and so transfers can be performed repeatedly until the DTE bit is cleared by the user.

Full Address Mode: The function of ETCR in normal mode differs from that in block transfer mode.

In normal mode, ETCRA functions as a 16-bit transfer counter. ETCRA is decremented by 1 each time a data transfer is performed, and transfer ends when the count reaches H'0000. ETCRB is not used in normal mode.

In block transfer mode, ETCRAL functions as an 8-bit block size counter and ETCRAH functions as a block size holding register. ETCRAL is decremented by 1 each time a 1-byte or 1-word transfer is performed, and when the count reaches H'00, ETCRAL is loaded with the value in ETCRAH. So by setting the block size in ETCRAH and ETCRAL, it is possible to repeatedly transfer blocks consisting of any desired number of bytes or words.

In block transfer mode, ETCRB functions as a 16-bit block transfer counter. ETCRB is decremented by 1 each time a block is transferred, and transfer ends when the count reaches H'0000.

7.3.4 DMA Control Registers (DMACRA and DMACRB)

DMACR controls the operation of each DMAC channel.

The DMA has four DMACR registers: DMACR_0A in channel 0 (channel 0A), DMACR_0B in channel 0 (channel 0B), DMACR_1A in channel 1 (channel 1A), and DMACR_1B in channel 1 (channel 1B).

In short address mode, channels A and B operate independently, and in full address mode, channels A and B operate together. The bit functions in the DMACR registers differ according to the transfer mode.

Short Address Mode:

- DMACR_0A, DMACR_0B, DMACR_1A, and DMARC_1B

Bit	Bit Name	Initial Value	R/W	Description
7	DTSZ	0	R/W	Data Transfer Size Selects the size of data to be transferred at one time. 0: Byte-size transfer 1: Word-size transfer
6	DTID	0	R/W	Data Transfer Increment/Decrement Selects incrementing or decrementing of MAR after every data transfer in sequential mode or repeat mode. In idle mode, MAR is neither incremented nor decremented. 0: MAR is incremented after a data transfer <ul style="list-style-type: none">• When DTSZ = 0, MAR is incremented by 1• When DTSZ = 1, MAR is incremented by 2 1: MAR is decremented after a data transfer <ul style="list-style-type: none">• When DTSZ = 0, MAR is decremented by 1• When DTSZ = 1, MAR is decremented by 2
5	RPE	0	R/W	Repeat Enable Used in combination with the DTIE bit in DMABCR to select the mode (sequential, idle, or repeat) in which transfer is to be performed. <ul style="list-style-type: none">• When DTIE = 0 (no transfer end interrupt) 0: Transfer in sequential mode 1: Transfer in repeat mode <ul style="list-style-type: none">• When DTIE = 1 (with transfer end interrupt) 0: Transfer in sequential mode 1: Transfer in idle mode
4	DTDIR	0	R/W	Data Transfer Direction Used in combination with the SAE bit in DMABCR to specify the data transfer direction (source or destination). The function of this bit is therefore different in dual address mode and single address mode. <ul style="list-style-type: none">• When SAE = 0 0: Transfer with MAR as source address and IOAR as destination address 1: Transfer with IOAR as source address and MAR as destination address <ul style="list-style-type: none">• When SAE = 1 0: Transfer with MAR as source address and $\overline{\text{DACK}}$ pin as write strobe 1: Transfer with $\overline{\text{DACK}}$ pin as read strobe and MAR as destination address

Bit	Bit Name	Initial Value	R/W	Description
3	DTF3	0	R/W	Data Transfer Factor 3 to 0
2	DTF2	0	R/W	<p>These bits select the data transfer factor (activation source). There are some differences in activation sources for channel A and channel B.</p> <ul style="list-style-type: none"> Channel A <p>0000: Setting prohibited</p> <p>0001: Activated by A/D converter conversion end interrupt</p> <p>0010: Setting prohibited</p> <p>0011: Setting prohibited</p> <p>0100: Activated by SCI channel 0 transmission complete interrupt</p> <p>0101: Activated by SCI channel 0 reception complete interrupt</p> <p>0110: Activated by SCI channel 1 transmission complete interrupt</p> <p>0111: Activated by SCI channel 1 reception complete interrupt</p> <p>1000: Activated by TPU channel 0 compare match/input capture A interrupt</p> <p>1001: Activated by TPU channel 1 compare match/input capture A interrupt</p> <p>1010: Activated by TPU channel 2 compare match/input capture A interrupt</p> <p>1011: Activated by TPU channel 3 compare match/input capture A interrupt</p> <p>1100: Activated by TPU channel 4 compare match/input capture A interrupt</p> <p>1101: Activated by TPU channel 5 compare match/input capture A interrupt</p> <p>1110: Setting prohibited</p> <p>1111: Setting prohibited</p>
1	DTF1	0	R/W	
0	DTF0	0	R/W

7.3.5 DMA Band Control Registers H and L (DMABCRH and DMABCRL)

DMABCR controls the operation of each DMAC channel. The bit functions in the DMACR registers differ according to the transfer mode.

Short Address Mode:

- DMABCRH

Bit	Bit Name	Initial Value	R/W	Description
15	FAE1	0	R/W	Full Address Enable 1 Specifies whether channel 1 is to be used in short address mode or full address mode. In short address mode, channels 1A and 1B can be used as independent channels. 0: Short address mode 1: Full address mode
14	FAE0	0	R/W	Full Address Enable 0 Specifies whether channel 0 is to be used in short address mode or full address mode. In short address mode, channels 0A and 0B can be used as independent channels. 0: Short address mode 1: Full address mode
13	SAE1	0	R/W	Single Address Enable 1 Specifies whether channel 1B is to be used for transfer in dual address mode or single address mode. This bit is invalid in full address mode. 0: Dual address mode 1: Single address mode

Bit	Bit Name	Initial Value	R/W	Description
12	SAE0	0	R/W	<p>Single Address Enable 0</p> <p>Specifies whether channel 0B is to be used for transfer in dual address mode or single address mode. This bit is invalid in full address mode.</p> <p>0: Dual address mode 1: Single address mode</p>
11	DTA1B	0	R/W	Data Transfer Acknowledge 1B
10	DTA1A	0	R/W	Data Transfer Acknowledge 1A
9	DTA0B	0	R/W	Data Transfer Acknowledge 0B
8	DTA0A	0	R/W	<p>Data Transfer Acknowledge 0A</p> <p>These bits enable or disable clearing when DMA transfer is performed for the internal interrupt source selected by the DTF3 to DTF0 bits in DMACR.</p> <p>If the DTA bit is set to 1 when DTE = 1, the internal interrupt source is cleared automatically by DMA transfer. When DTE = 1 and DTA = 1, the internal interrupt source does not issue an interrupt request to the CPU or DTC.</p> <p>If the DTA bit is cleared to 0 when DTE = 1, the internal interrupt source is not cleared when a transfer is performed, and can issue an interrupt request to the CPU or DTC in parallel. In this case, the interrupt source should be cleared by the CPU or DTC transfer.</p> <p>When DTE = 0, the internal interrupt source issues an interrupt request to the CPU or DTC regardless of the DTA bit setting.</p>

- DMABCRL

Bit	Bit Name	Initial Value	R/W	Description
7	DTE1B	0	R/W	Data Transfer Enable 1B
6	DTE1A	0	R/W	Data Transfer Enable 1A
5	DTE0B	0	R/W	Data Transfer Enable 0B
4	DTE0A	0	R/W	Data Transfer Enable 0A
				<p>If the DTIE bit is set to 1 when DTE = 0, the DMAC regards this as indicating the end of a transfer, and issues a transfer end interrupt request to the CPU or DTC.</p> <p>When DTE = 0, data transfer is enabled and the DMAC ignores the activation source selected by the DTF3 to DTF0 bits in DMACR.</p> <p>When DTE = 1, data transfer is enabled and the DMAC waits for a request by the activation source selected by the DTF3 to DTF0 bits in DMACR. When a request is issued by the activation source, DMA transfer is executed.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • When initialization is performed • When the specified number of transfers have been completed in a transfer mode other than repeat mode • When 0 is written to the DTE bit to forcibly suspend the transfer, or for a similar reason <p>[Setting condition]</p> <p>When 1 is written to the DTE bit after reading DTE = 0</p>

Bit	Bit Name	Initial Value	R/W	Description
3	DTIE1B	0	R/W	Data Transfer End Interrupt Enable 1B
2	DTIE1A	0	R/W	Data Transfer End Interrupt Enable 1A
1	DTIE0B	0	R/W	Data Transfer End Interrupt Enable 0B
0	DTIE0A	0	R/W	Data Transfer End Interrupt Enable 0A
<p>These bits enable or disable an interrupt to the CPU or DTC when transfer ends. If the DTIE bit is set to 1 when DTE = 0, the DMAC regards this as indicating the end of a transfer, and issues a transfer end interrupt request to the CPU or DTC.</p> <p>A transfer end interrupt can be canceled either by clearing the DTIE bit to 0 in the interrupt handling routine, or by performing processing to continue transfer by setting the transfer counter and address register again, and then setting the DTE bit to 1.</p>				

Full Address Mode:

- DMABCRH

Bit	Bit Name	Initial Value	R/W	Description
15	FAE1	0	R/W	Full Address Enable 1 Specifies whether channel 1 is to be used in short address mode or full address mode. In full address mode, channels 1A and 1B are used together as channel 1. 0: Short address mode 1: Full address mode
14	FAE0	0	R/W	Full Address Enable 0 Specifies whether channel 0 is to be used in short address mode or full address mode. In full address mode, channels 0A and 0B are used together as channel 0. 0: Short address mode 1: Full address mode

When DTME0 is cleared to 0 while this bit is set to 1, the DMAC regards this as indicating a break in the transfer, and issues a transfer break interrupt request to the CPU or DTC.</p> <p>A transfer break interrupt can be canceled either by clearing the DTIE0B bit to 0 in the interrupt handling routine, or by performing processing to continue transfer by setting the DTME0 bit to 1.</p>
0	DTIE0A	0	R/W	<p>Data Transfer End Interrupt Enable 0A</p> <p>Enables or disables an interrupt to the CPU or DTC when transfer ends. When DTE0 is cleared to 0 while this bit is set to 1, the DMAC regards this as indicating the end of a transfer, and issues a transfer end interrupt request to the CPU or DTC.</p> <p>A transfer end interrupt can be canceled either by clearing the DTIE0A bit to 0 in the interrupt handling routine, or by performing processing to continue transfer by setting the transfer counter and address register again, and then setting the DTE0 bit to 1.</p>

7.3.6 DMA Write Enable Register (DMAWER)

The DMAC can activate the DTC with a transfer end interrupt, rewrite the channel on which the transfer ended using a DTC chain transfer, and then reactivate the DTC. DMAWER applies restrictions for changing all bits of DMACR, and specific bits for DMATCR and DMABCR for the specific channel, to prevent inadvertent rewriting of registers other than those for the channel concerned. The restrictions applied by DMAWER are valid for the DTC.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	R	Reserved These bits are always read as 0 and cannot be modified.
3	WE1B	0	R/W	Write Enable 1B Enables or disables writes to all bits in DMACR1B, bits 11, 7, and 3 in DMABCR, and bit 5 in DMATCR. 0: Writes are disabled 1: Writes are enabled
2	WE1A	0	R/W	Write Enable 1A Enables or disables writes to all bits in DMACR1A, and bits 10, 6, and 2 in DMABCR. 0: Writes are disabled 1: Writes are enabled
1	WE0B	0	R/W	Write Enable 0B Enables or disables writes to all bits in DMACR0B, bits 9, 5, and 1 in DMABCR, and bit 4 in DMATCR. 0: Writes are disabled 1: Writes are enabled
0	WE0A	0	R/W	Write Enable 0A Enables or disables writes to all bits in DMACR0A, and bits 8, 4, and 0 in DMABCR. 0: Writes are disabled 1: Writes are enabled

Figure 7.2 shows the transfer areas for activating the DTC with a channel 0A transfer end interrupt request, and reactivating channel 0A. The address register and count register areas are set again during the first DTC transfer, then the control register area is set again during the second DTC chain transfer. When re-setting the control register area, perform masking by setting bits in DMAWER to prevent modification of the contents of other channels.

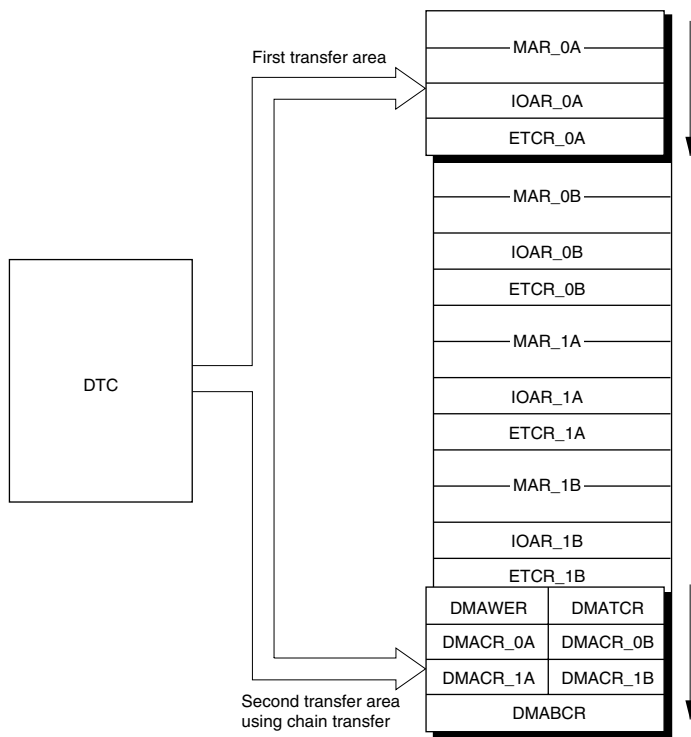

Figure 7.2 Areas for Register Re-Setting by DTC (Channel 0A)

Writes by the DTC to bits 15 to 12 (FAE and SAE) in DMABCR are invalid regardless of the DMAWER settings. These bits should be changed, if necessary, by CPU processing.

In writes by the DTC to bits 7 to 4 (DTE) in DMABCR, 1 can be written without first reading 0. To reactivate a channel set to full address mode, write 1 to both Write Enable A and Write Enable B for the channel to be reactivated.

MAR, IOAR, and ETCR can always be written to regardless of the DMAWER settings. When modifying these registers, the channel to be modified should be halted.

7.3.7 DMA Terminal Control Register (DMATCR)

DMATCR controls enabling or disabling of output from the DMAC transfer end pin. A port can be set for output automatically, and a transfer end signal output, by setting the appropriate bit.

In short address mode, the TEND pin is only available for channel B. The transfer end signal indicates the transfer cycle in which the transfer counter has become 0 regardless of the transfer source. Note however that the transfer end signal exceptionally indicates the transfer cycle in which the block counter has become 0 in block transfer mode.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	TEE1	0	R/W	Transfer End Enable 1 Enables or disables transfer end pin 1 ($\overline{TEND1}$) output. 0: $\overline{TEND1}$ pin output disabled 1: $\overline{TEND1}$ pin output enabled
4	TEE0	0	R/W	Transfer End Enable 0 Enables or disables transfer end pin 0 ($\overline{TEND0}$) output. 0: $\overline{TEND0}$ pin output disabled 1: $\overline{TEND0}$ pin output enabled
3 to 0	—	0	—	Reserved These bits are always read as 0 and cannot be modified.

7.4 Activation Sources

DMAC activation sources consist of internal interrupt requests, external requests, and auto-requests. The DMAC activation sources that can be specified depend on the transfer mode and channel, as shown in table 7.3.

Table 7.3 DMAC Activation Sources

Activation Source		Short Address Mode		Full Address Mode	
		Channels 0A and 1A	Channels 0B and 1B	Normal Mode	Block Transfer Mode
Internal interrupts	ADI	O	O	X	O
	TXI0	O	O	X	O
	RXI0	O	O	X	O
	TXI1	O	O	X	O
	RXI1	O	O	X	O
	TGI0A	O	O	X	O
	TGI1A	O	O	X	O
	TGI2A	O	O	X	O
	TGI3A	O	O	X	O

	TGI5A	O	O	X	O
External requests	DREQ pin falling edge input	X	O	O	O
	DREQ pin low-level input	X	O	O	O
Auto-request		X	X	O	X

Legend

O: Can be specified

X: Cannot be specified

7.4.1 Activation by Internal Interrupt Request

An interrupt request selected as a DMAC activation source can also simultaneously generate an interrupt request for the CPU or DTC. For details, see section 5, Interrupt Controller.

With activation by an internal interrupt request, the DMAC accepts the interrupt request independently of the interrupt controller. Consequently, interrupt controller priority settings are irrelevant.

If the DMAC is activated by a CPU interrupt source or an interrupt request that is not used as a DTC activation source ($DTA = 1$), the interrupt request flag is cleared automatically by the DMA transfer. With ADI, TXI and RXI interrupts, however, the interrupt source flag is not cleared unless the relevant register is accessed in a DMA transfer. If the same interrupt is used as an activation source for more than one channel, the interrupt request flag is cleared when the highest-priority channel is activated. Transfer requests for other channels are held pending in the DMAC, and activation is carried out in order of priority.

When $DTE = 0$ after completion of a transfer, an interrupt request from the selected activation source is not sent to the DMAC, regardless of the DTA bit setting. In this case, the relevant interrupt request is sent to the CPU or DTC.

In case of overlap with a CPU interrupt source or DTC activation source ($DTA = 0$), the interrupt request flag is not cleared by the DMAC.

7.4.2 Activation by External Request

If an external request (\overline{DREQ} pin) is specified as a DMAC activation source, the relevant port should be set to input mode in advance. Level sensing or edge sensing can be used for external requests.

External request operation in normal mode of short address mode or full address mode is described below.

When edge sensing is selected, a byte or word is transferred each time a high-to-low transition is detected on the \overline{DREQ} pin. The next data transfer may not be performed if the next edge is input before data transfer is completed.

When level sensing is selected, the DMAC stands by for a transfer request while the \overline{DREQ} pin is held high. While the \overline{DREQ} pin is held low, transfers continue in succession, with the bus being released each time a byte or word is transferred. If the \overline{DREQ} pin goes high in the middle of a transfer, the transfer is interrupted and the DMAC stands by for a transfer request.

7.4.3 Activation by Auto-Request

Auto-request is activated by register setting only, and transfer continues to the end. With auto-request activation, cycle steal mode or burst mode can be selected.

In cycle steal mode, the DMAC releases the bus to another bus master each time a byte or word is transferred. DMA and CPU cycles are usually repeated alternately. In burst mode, the DMAC keeps possession of the bus until the end of the transfer so that transfer is performed continuously.

7.5 Operation

7.5.1 Transfer Modes

Table 7.4 lists the DMAC transfer modes.

Table 7.4 DMAC Transfer Modes

Transfer Mode	Transfer Source	Remarks
Short address mode	<ul style="list-style-type: none">• TPU channel 0 to 5 compare match/input capture A interrupt• SCI transmission complete interrupt• SCI reception complete interrupt• A/D converter conversion end interrupt• External request	<ul style="list-style-type: none">• Up to 4 channels can operate independently• External request applies to channel B only• Single address mode applies to channel B only

	<ul style="list-style-type: none"> Transfer of 1-block, size selected for a single transfer request Number of transfers: 1 to 65,536 Source or destination can be selected as block area Block size: 1 to 256 bytes or word 		

7.5.2 Sequential Mode

Sequential mode can be specified by clearing the RPE bit in DMACR to 0. In sequential mode, MAR is updated after each byte or word transfer in response to a single transfer request, and this is executed the number of times specified in ETCR. One address is specified by MAR, and the other by IOAR. The transfer direction can be specified by the DTDIR bit in DMACR.

Table 7.5 summarizes register functions in sequential mode.

Table 7.5 Register Functions in Sequential Mode

Register	Function		Initial Setting	Operation
	DTDIR = 0	DTDIR = 1		
<div>230<div>⋮MAR⋮</div></div>	Source address register	Destination address register	Start address of transfer destination or transfer source	Incremented/ decremented every transfer
<div>23150<div>H'FFIOAR</div></div>	Destination address register	Source address register	Start address of transfer source or transfer destination	Fixed
<div>150<div>ETCR</div></div>	Transfer counter		Number of transfers	Decrement every transfer; transfer ends when count reaches H'0000

MAR specifies the start address of the transfer source or transfer destination as 24 bits. MAR is incremented or decremented by 1 or 2 each time a byte or word is transferred. IOAR specifies the lower 16 bits of the other address. The 8 bits above IOAR have a value of H'FF.

Figure 7.3 illustrates operation in sequential mode.

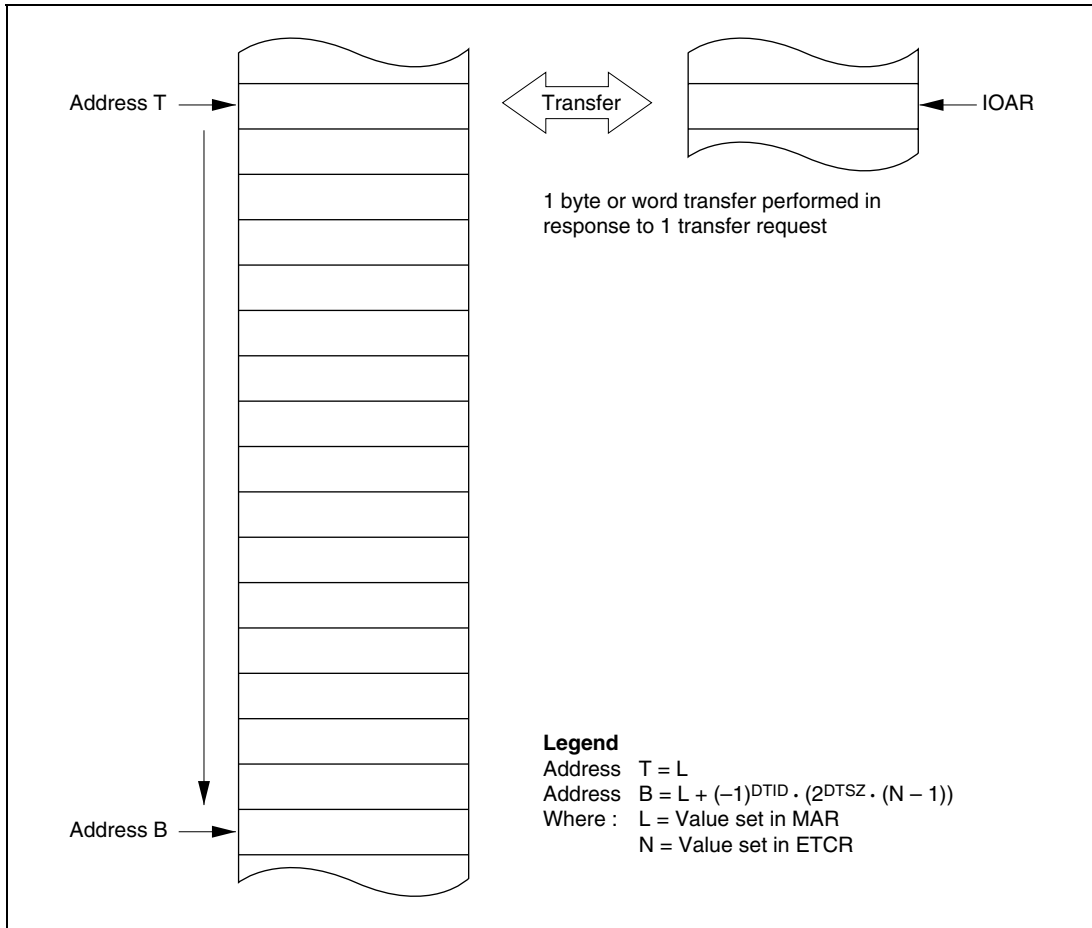

Figure 7.3 Operation in Sequential Mode

The number of transfers is specified as 16 bits in ETCR. ETCR is decremented by 1 each time a data transfer is executed, and when its value reaches H'0000, the DTE bit is cleared and data transfer ends. If the DTIE bit is set to 1 at this time, an interrupt request is sent to the CPU or DTC. The maximum number of transfers, when H'0000 is set in ETCR, is 65,536.

Transfer requests (activation sources) consist of A/D converter conversion end interrupts, external requests, SCI transmission complete and reception complete interrupts, and TPU channel 0 to 5 compare match/input capture A interrupts. External requests can only be specified for channel B.

Figure 7.4 shows an example of the setting procedure for sequential mode.

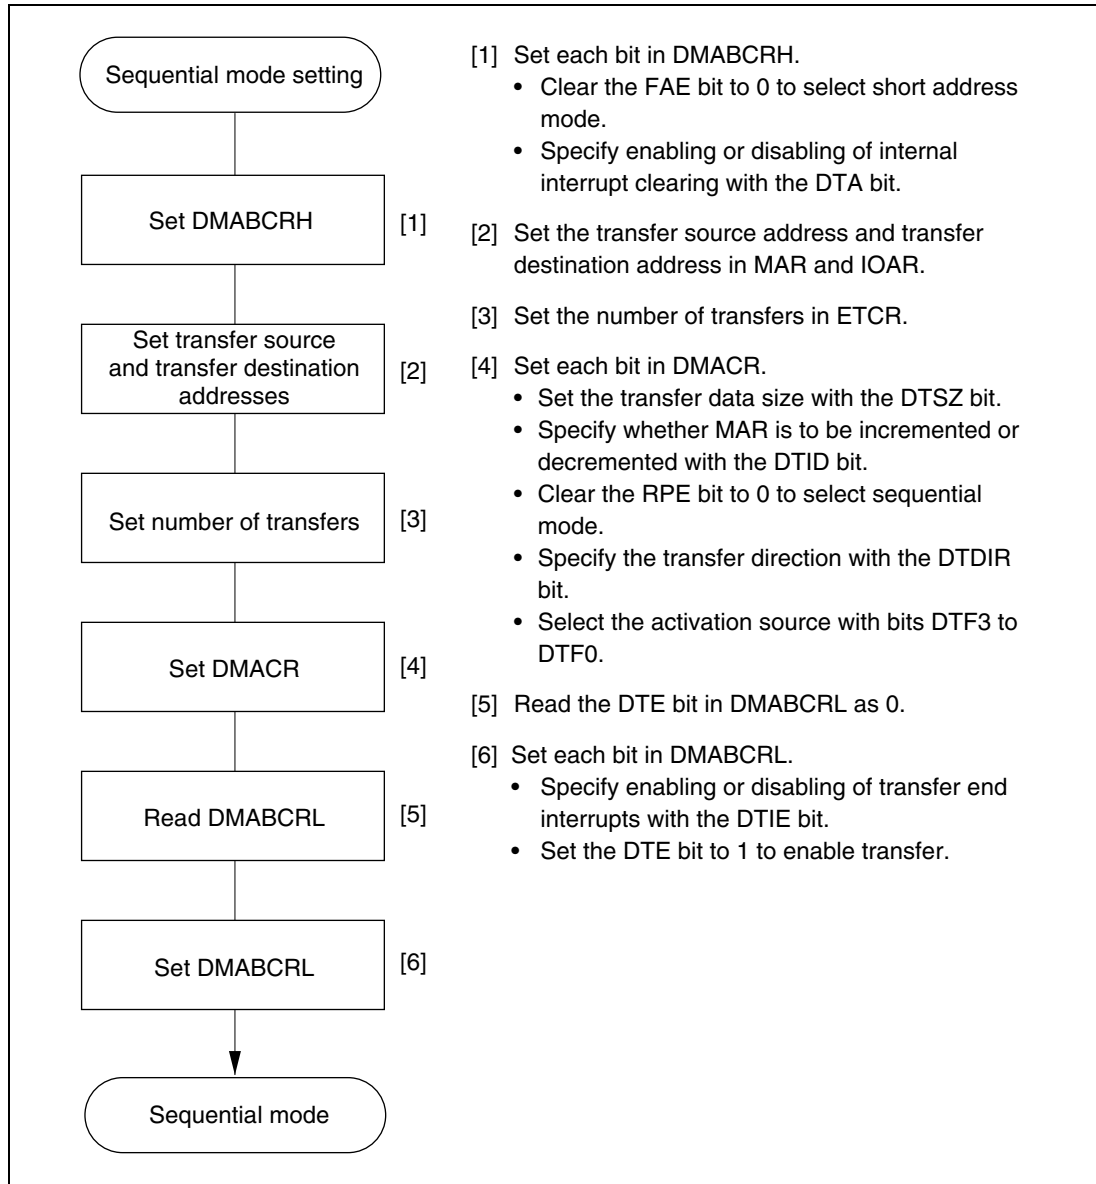

Figure 7.4 Example of Sequential Mode Setting Procedure

7.5.3 Idle Mode

Idle mode can be specified by setting the RPE bit in DMACR and DTIE bit in DMABCRL to 1. In idle mode, one byte or word is transferred in response to a single transfer request, and this is executed the number of times specified in ETCR. One address is specified by MAR, and the other

by IOAR. The transfer direction can be specified by the DTDIR bit in DMACR. Table 7.6 summarizes register functions in idle mode.

Table 7.6 Register Functions in Idle Mode

Register	Function		Initial Setting	Operation
	DTDIR = 0	DTDIR = 1		
<div>230<div><div></div><div>MAR</div><div></div></div></div>	Source address register	Destination address register	Start address of transfer destination or transfer source	Fixed
<div>23150<div><div>H'FF</div><div>IOAR</div></div></div>	Destination address register	Source address register	Start address of transfer source or transfer destination	Fixed
<div>150<div><div>ETCR</div></div></div>	Transfer counter		Number of transfers	Decrement every transfer; transfer ends when count reaches H'0000

MAR specifies the start address of the transfer source or transfer destination as 24 bits. MAR is neither incremented nor decremented by a data transfer. IOAR specifies the lower 16 bits of the other address. The upper 8 bits of IOAR have a value of H'FF.

Figure 7.5 illustrates operation in idle mode.

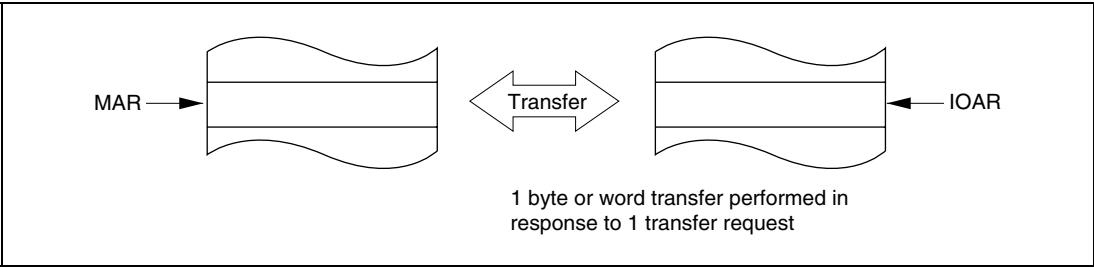

Figure 7.5 Operation in Idle Mode

The number of transfers is specified as 16 bits in ETCR. ETCR is decremented by 1 each time a transfer is executed, and when its value reaches H'0000, the DTE bit is cleared and data transfer ends. If the DTIE bit is set to 1 at this time, an interrupt request is sent to the CPU or DTC. The maximum number of transfers, when H'0000 is set in ETCR, is 65,536.

Transfer requests (activation sources) consist of A/D converter conversion end interrupts, external requests, SCI transmission complete and reception complete interrupts, and TPU channel 0 to 5 compare match/input capture A interrupts. External requests can only be specified for channel B.

Figure 7.6 shows an example of the setting procedure for idle mode.

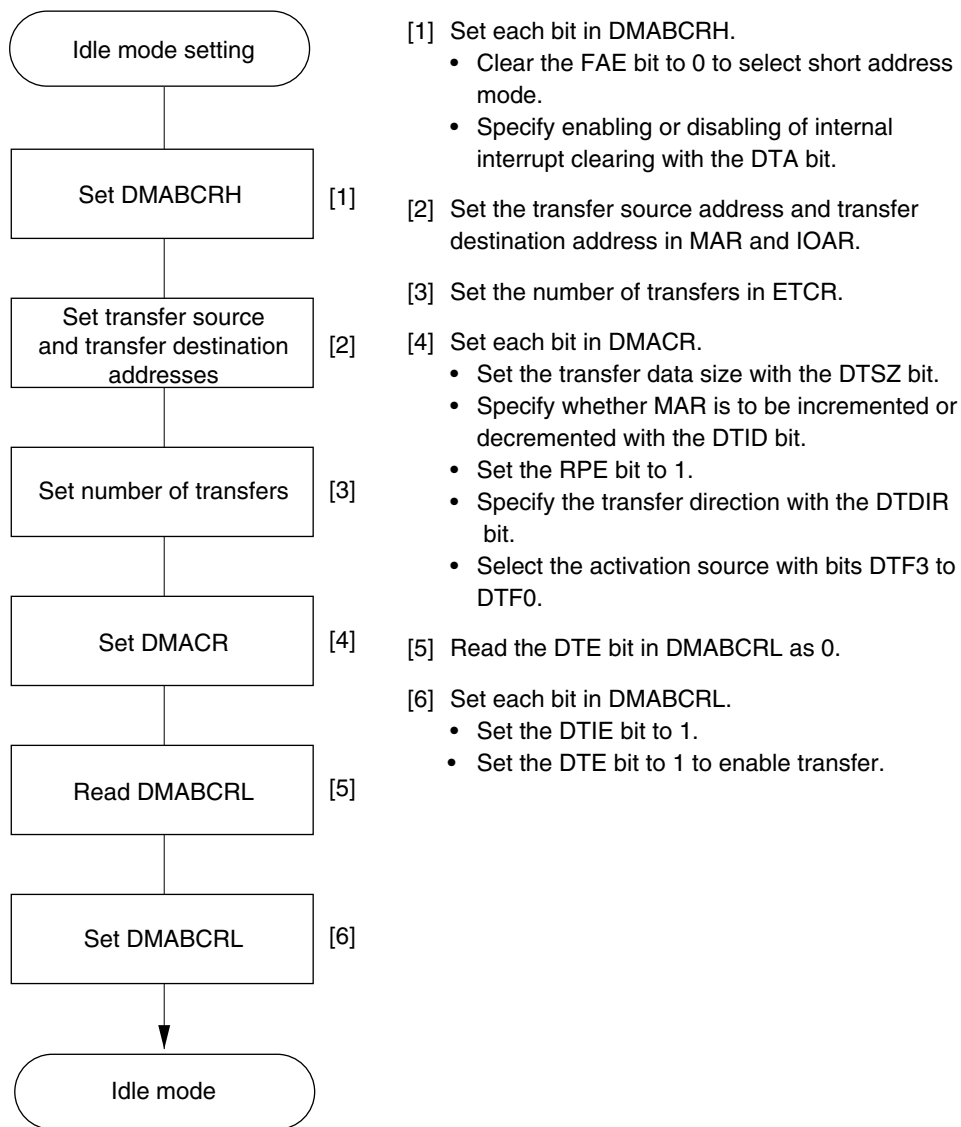

Figure 7.6 Example of Idle Mode Setting Procedure

7.5.4 Repeat Mode

Repeat mode can be specified by setting the RPE bit in DMACR to 1, and clearing the DTIE bit in DMABCRL to 0. In repeat mode, MAR is updated after each byte or word transfer in response to a single transfer request, and this is executed the number of times specified in ETCRL. On completion of the specified number of transfers, MAR and ETCRL are automatically restored to

their original settings and operation continues. One address is specified by MAR, and the other by IOAR. The transfer direction can be specified by the DTDIR bit in DMACR. Table 7.7 summarizes register functions in repeat mode.

Table 7.7 Register Functions in Repeat Mode

Register	Function		Initial Setting	Operation
	DTDIR = 0	DTDIR = 1		
<div style="display: flex; justify-content: space-between; align-items: center;"> 23 0 </div> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <div style="display: flex; justify-content: space-between; align-items: center;"> 23 15 0 </div> <div style="border: 1px solid black; padding: 2px; text-align: center;">MAR</div> </div>	Source address register	Destination address register	Start address of transfer destination or transfer source	Incremented/decremented every transfer. Initial setting is restored when value reaches H'0000
<div style="display: flex; justify-content: space-between; align-items: center;"> 23 15 0 </div> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <div style="display: flex; justify-content: space-between; align-items: center;"> 23 15 0 </div> <div style="border: 1px solid black; padding: 2px; text-align: center;">H'FF</div> <div style="border: 1px solid black; padding: 2px; text-align: center;">IOAR</div> </div>	Destination address register	Source address register	Start address of transfer source or transfer destination	Fixed
<div style="display: flex; justify-content: space-between; align-items: center;"> 7 0 </div> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <div style="display: flex; justify-content: space-between; align-items: center;"> 7 0 </div> <div style="border: 1px solid black; padding: 2px; text-align: center;">ETCRH</div> </div>	Holds number of transfers		Number of transfers	Fixed
<div style="display: flex; justify-content: space-between; align-items: center;"> 7 0 </div> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <div style="display: flex; justify-content: space-between; align-items: center;"> 7 0 </div> <div style="border: 1px solid black; padding: 2px; text-align: center;">ETCRL</div> </div>	Transfer counter		Number of transfers	Decrement every transfer. Loaded with ETCRH value when count reaches H'00

MAR specifies the start address of the transfer source or transfer destination as 24 bits. MAR is incremented or decremented by 1 or 2 each time a byte or word is transferred. IOAR specifies the lower 16 bits of the other address. The upper 8 bits of IOAR have a value of H'FF. The number of transfers is specified as 8 bits by ETCRH and ETCRL. The maximum number of transfers, when H'00 is set in both ETCRH and ETCRL, is 256.

In repeat mode, ETCRL functions as the transfer counter, and ETCRH is used to hold the number of transfers. ETCRL is decremented by 1 each time a data transfer is executed, and when its value reaches H'00, it is loaded with the value in ETCRH. At the same time, the value set in MAR is restored in accordance with the values of the DTSZ and DTID bits in DMACR. The MAR restoration operation is as shown below.

$$\text{MAR} = \text{MAR} - (-1)^{\text{DTID}} \cdot 2^{\text{DTSZ}} \cdot \text{ETCRH}$$

The same value should be set in ETCRH and ETCRL.

In repeat mode, operation continues until the DTE bit in DMABCRL is cleared. To end the transfer operation, therefore, the DTE bit should be cleared to 0. A transfer end interrupt request is

not sent to the CPU or DTC. By setting the DTE bit to 1 again after it has been cleared, the operation can be restarted from the transfer after that terminated when the DTE bit was cleared.

Figure 7.7 illustrates operation in repeat mode.

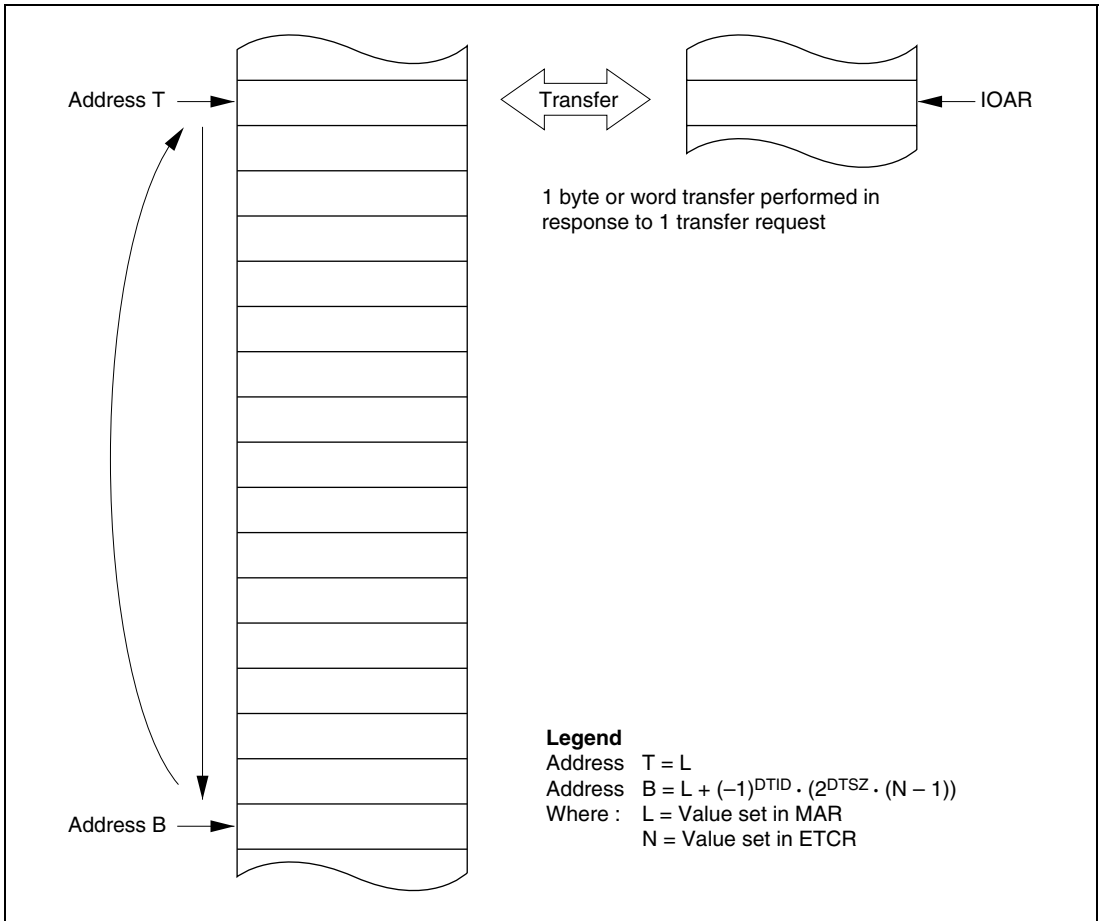

Figure 7.7 Operation in Repeat mode

Transfer requests (activation sources) consist of A/D converter conversion end interrupts, external requests, SCI transmission complete and reception complete interrupts, and TPU channel 0 to 5 compare match/input capture A interrupts. External requests can only be specified for channel B.

Figure 7.8 shows an example of the setting procedure for repeat mode.

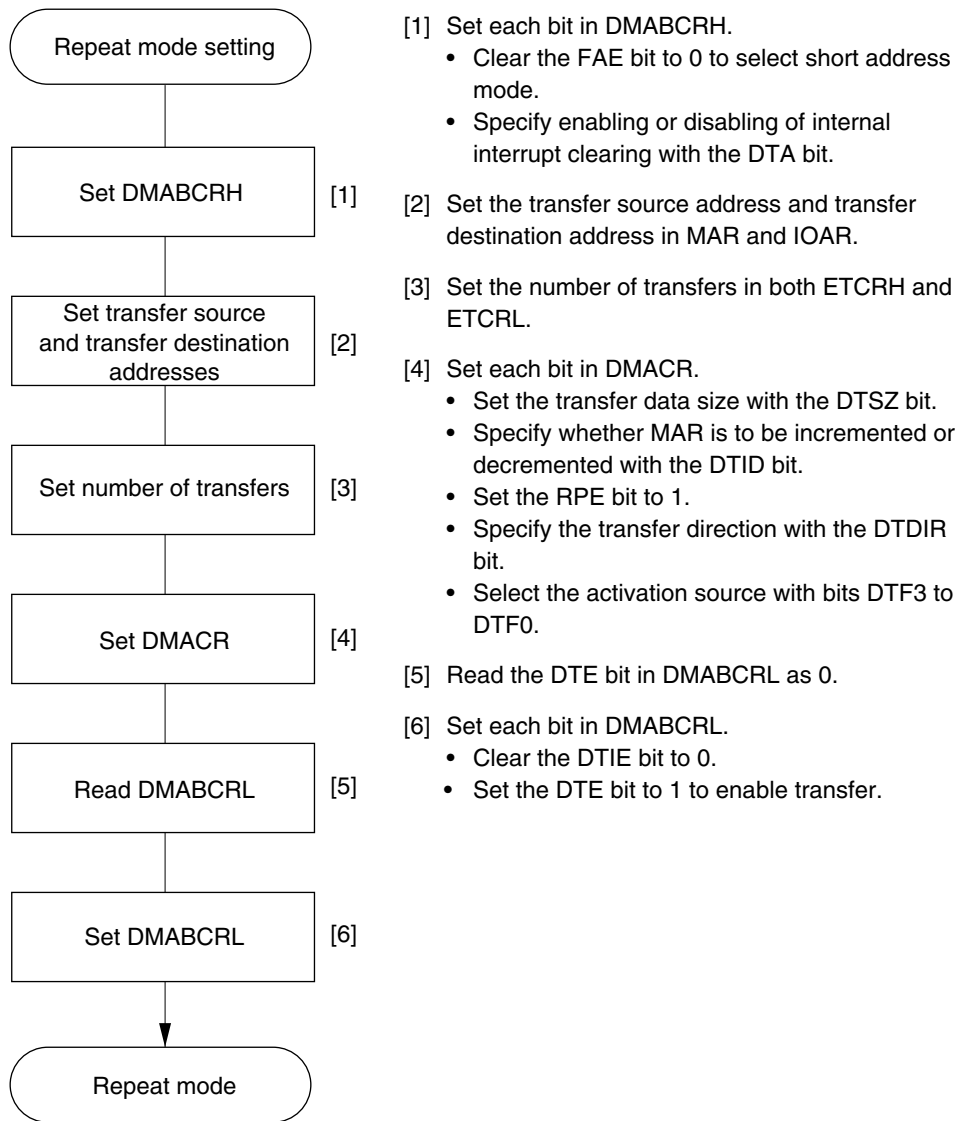

Figure 7.8 Example of Repeat Mode Setting Procedure

7.5.5 Single Address Mode

Single address mode can only be specified for channel B. This mode can be specified by setting the SAE bit in DMABCRH to 1 in short address mode.

One address is specified by MAR, and the other is set automatically to the data transfer acknowledge pin ($\overline{\text{DACK}}$). The transfer direction can be specified by the DTDIR bit in DMACR. Table 7.8 summarizes register functions in single address mode.

Table 7.8 Register Functions in Single Address Mode

Register	Function		Initial Setting	Operation
	DTDIR = 0	DTDIR = 1		
<div> <div>23</div> <div>0</div> <div> <div></div> <div>MAR</div> <div></div> </div> </div>	Source address register	Destination address register	Start address of transfer destination or transfer source	See sections 7.5.2, Sequential Mode, 7.5.3, Idle Mode, and 7.5.4, Repeat Mode.
$\overline{\text{DACK}}$ pin	Write strobe	Read strobe	(Set automatically by SAE bit; IOAR is invalid)	Strobe for external device
<div> <div>15</div> <div>0</div> <div> <div></div> <div>ETCR</div> <div></div> </div> </div>	Transfer counter		Number of transfers	See sections 7.5.2, Sequential Mode, 7.5.3, Idle Mode, and 7.5.4, Repeat Mode.

MAR specifies the start address of the transfer source or transfer destination as 24 bits. IOAR is invalid; in its place the strobe for external devices ($\overline{\text{DACK}}$) is output.

Figure 7.9 illustrates operation in single address mode (when sequential mode is specified).

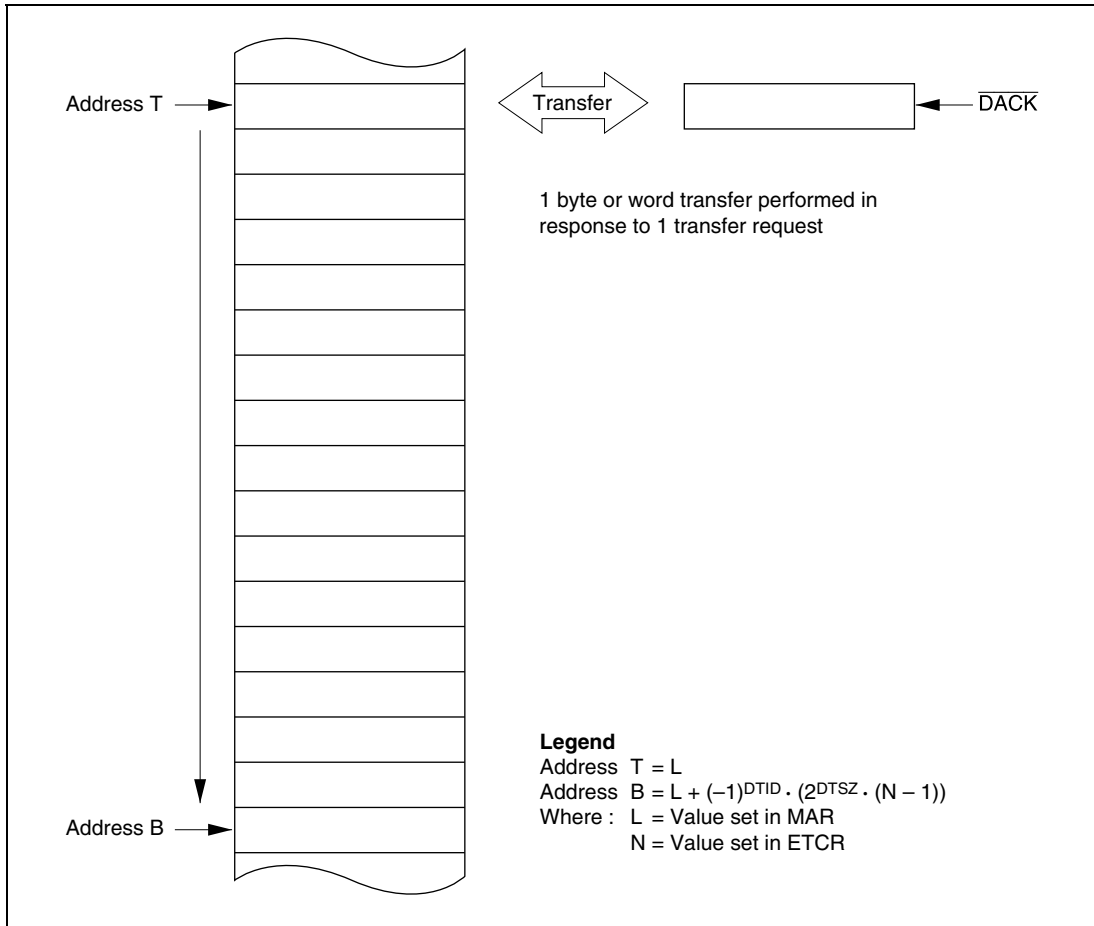

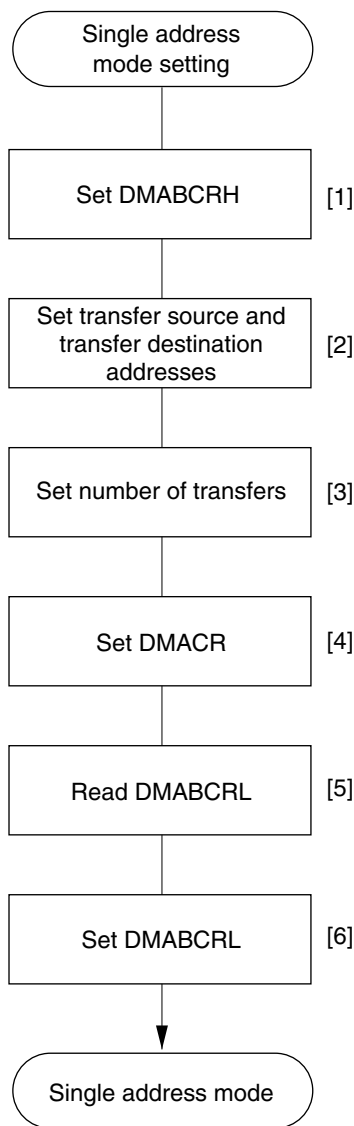

Figure 7.9 Operation in Single Address Mode (When Sequential Mode is Specified)

Figure 7.10 shows an example of the setting procedure for single address mode (when sequential mode is specified).

- [1] Set each bit in DMABCRH.
 - Clear the FAE bit to 0 to select short address mode.
 - Set the SAE bit to 1 to select single address mode.
 - Specify enabling or disabling of internal interrupt clearing with the DTA bit.
- [2] Set the transfer source address/transfer destination address in MAR.
- [3] Set the number of transfers in ETCR.
- [4] Set each bit in DMACR.
 - Set the transfer data size with the DTSZ bit.
 - Specify whether MAR is to be incremented or decremented with the DTID bit.
 - Clear the RPE bit to 0 to select sequential mode.
 - Specify the transfer direction with the DTDIR bit.
 - Select the activation source with bits DTF3 to DTF0.
- [5] Read the DTE bit in DMABCRL as 0.
- [6] Set each bit in DMABCRL.
 - Specify enabling or disabling of transfer end interrupts with the DTIE bit.
 - Set the DTE bit to 1 to enable transfer.

Figure 7.10 Example of Single Address Mode Setting Procedure (When Sequential Mode is Specified)

7.5.6 Normal Mode

In normal mode, transfer is performed with channels A and B used in combination. Normal mode can be specified by setting the FAE bit in DMABCRH to 1 and clearing the BLKE bit in DMACRA to 0. In normal mode, MAR is updated after data transfer of a byte or word in response

to a single transfer request, and this is executed the number of times specified in ETCRA. The transfer source is specified by MARA, and the transfer destination by MARB. Table 7.9 summarizes register functions in normal mode.

Table 7.9 Register Functions in Normal Mode

Register	Function	Initial Setting	Operation
<div>23<div>0</div><div>MARA</div></div>	Source address register	Start address of transfer source	Incremented/decremented every transfer, or fixed
<div>23<div>0</div><div>MARB</div></div>	Destination address register	Start address of transfer destination	Incremented/decremented every transfer, or fixed
<div>15<div>0</div><div>ETCRA</div></div>	Transfer counter	Number of transfers	Decrement every transfer; transfer ends when count reaches H'0000

MARA and MARB specify the start addresses of the transfer source and transfer destination, respectively, as 24 bits. MAR can be incremented or decremented by 1 or 2 each time a byte or word is transferred, or can be fixed. Incrementing, decrementing, or holding a fixed value can be set separately for MARA and MARB.

The number of transfers is specified by ETCRA as 16 bits. ETCRA is decremented by 1 each time a transfer is performed, and when its value reaches H'0000 the DTE bit in DMABCRL is cleared and transfer ends. If the DTIE bit in DMABCRL is set to 1 at this time, an interrupt request is sent to the CPU or DTC. The maximum number of transfers, when H'0000 is set in ETCRA, is 65,536.

Figure 7.11 illustrates operation in normal mode.

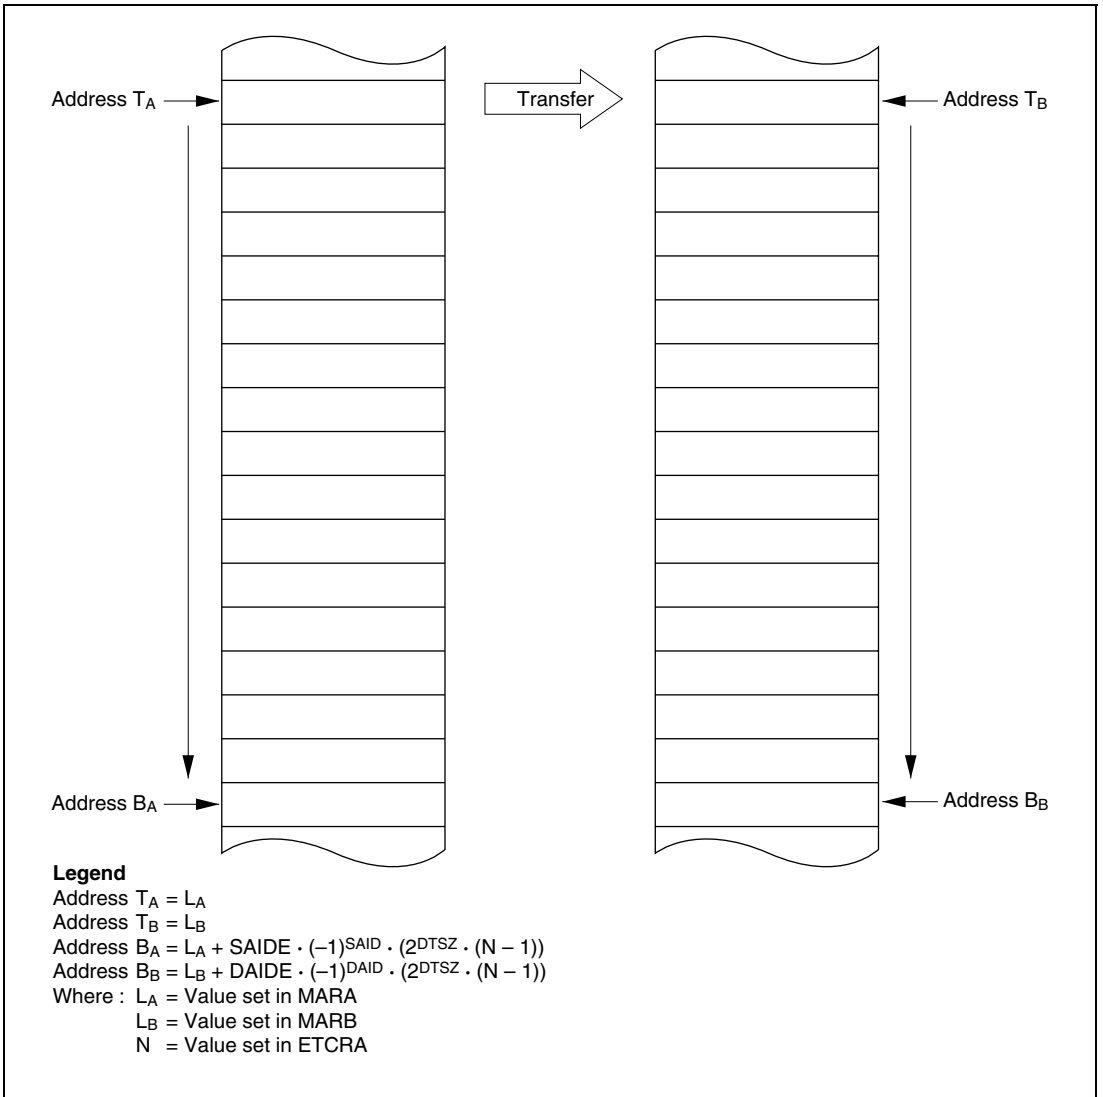

Figure 7.11 Operation in Normal Mode

Transfer requests (activation sources) are external requests and auto-requests. With auto-request, the DMAC is only activated by register setting, and the specified number of transfers are performed automatically. With auto-request, cycle steal mode or burst mode can be selected. In cycle steal mode, the bus is released to another bus master each time a transfer is performed. In burst mode, the bus is held continuously until transfer ends.

Figure 7.12 shows an example of the setting procedure for normal mode.

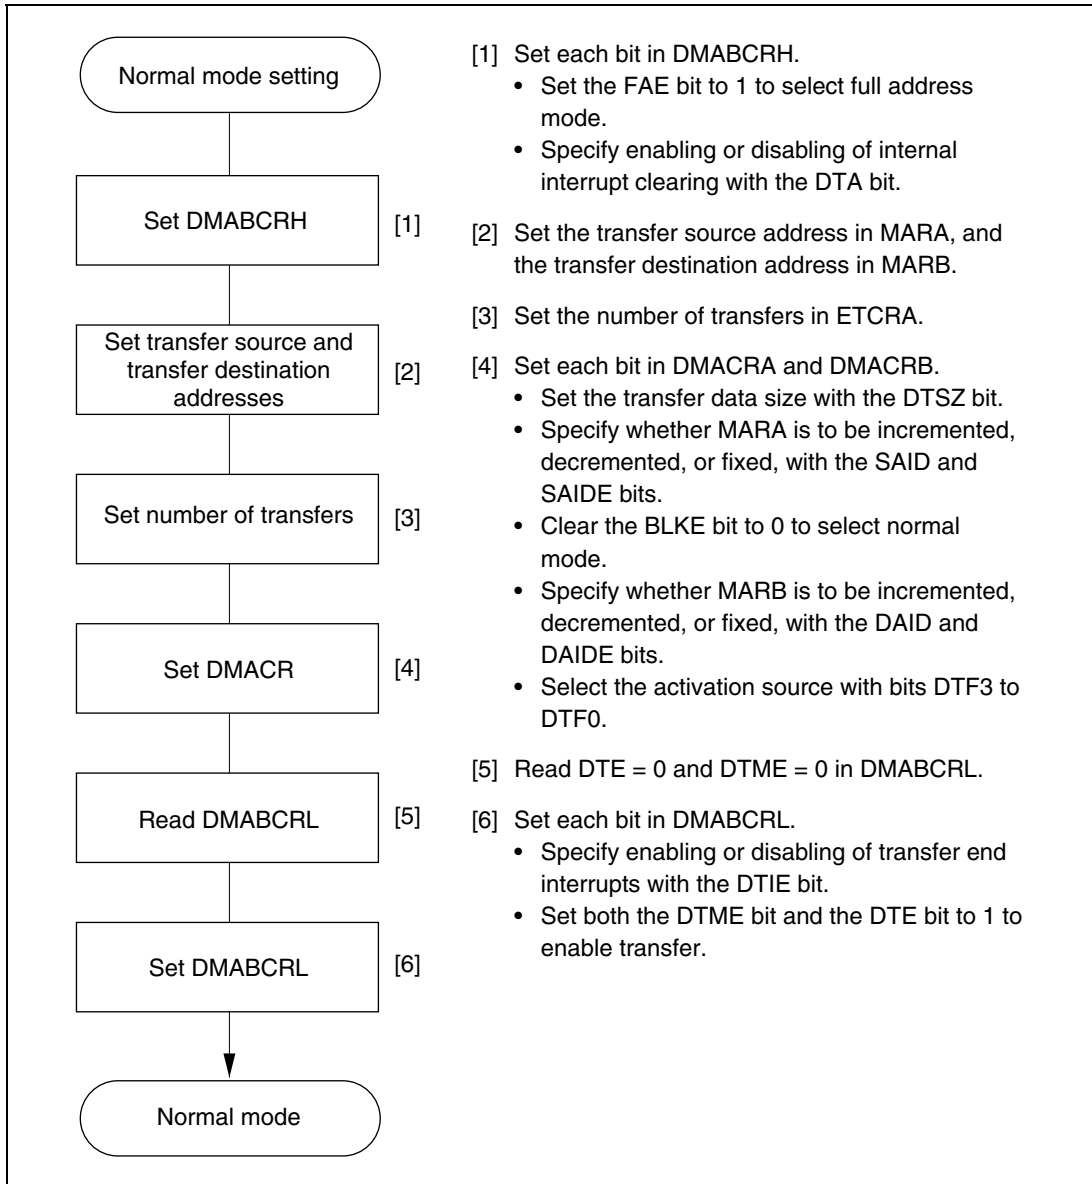

Figure 7.12 Example of Normal Mode Setting Procedure

7.5.7 Block Transfer Mode

In block transfer mode, data transfer is performed with channels A and B used in combination. Block transfer mode can be specified by setting the FAE bit in DMABCRH and the BLKE bit in DMACRA to 1. In block transfer mode, a data transfer of the specified block size is carried out in response to a single transfer request, and this is executed for the number of times specified in

ETCRB. The transfer source is specified by MARA, and the transfer destination by MARB. Either the transfer source or the transfer destination can be selected as a block area (an area composed of a number of bytes or words). Table 7.10 summarizes register functions in block transfer mode.

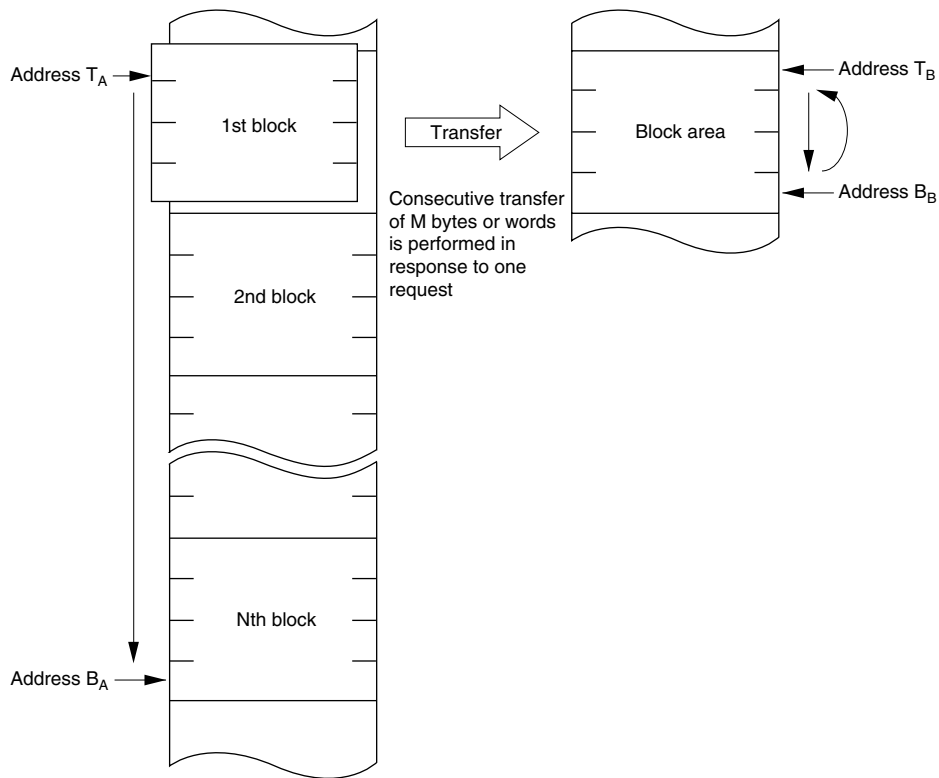

Table 7.10 Register Functions in Block Transfer Mode

Register	Function	Initial Setting	Operation
<div>230<div> : MARA : </div></div>	Source address register	Start address of transfer source	Incremented/decremented every transfer, or fixed
<div>230<div> : MARB : </div></div>	Destination address register	Start address of transfer destination	Incremented/decremented every transfer, or fixed
<div>70<div>ETCRAH</div></div>	Holds block size	Block size	Fixed
<div>70<div>ETCRAL</div></div>	Block size counter	Block size	Decrement every transfer; ETCRH value copied when count reaches H'00
<div>150<div>ETCRB</div></div>	Block transfer counter	Number of block transfers	Decrement every block transfer; transfer ends when count reaches H'0000

MARA and MARB specify the start addresses of the transfer source and transfer destination, respectively, as 24 bits. MAR can be incremented or decremented by 1 or 2 each time a byte or word is transferred, or can be fixed. Incrementing, decrementing, or holding a fixed value can be set separately for MARA and MARB. Whether a block is to be designated for MARA or for MARB is specified by the BLKDIR bit in DMACRA.

To specify the number of transfers, if M is the size of one block (where M = 1 to 256) and N transfers are to be performed (where N = 1 to 65,536), M is set in both ETCRAH and ETCRAL, and N in ETCRB.

Figure 7.13 illustrates operation in block transfer mode when MARB is designated as a block area.

Legend

Address $T_A = L_A$

Address $T_B = L_B$

Address $B_A = L_A + SAIDE \cdot (-1)^{SAID} \cdot (2^{DTSZ} \cdot (M \cdot N - 1))$

Address $B_B = L_B + DAIDE \cdot (-1)^{DAID} \cdot (2^{DTSZ} \cdot (N - 1))$

Where : L_A = Value set in MARA

L_B = Value set in MARB

N = Value set in ETCRB

M = Value set in ETCRAH and ETCRAL

Figure 7.13 Operation in Block Transfer Mode (BLKDIR = 0)

Figure 7.14 illustrates operation in block transfer mode when MARA is designated as a block area.

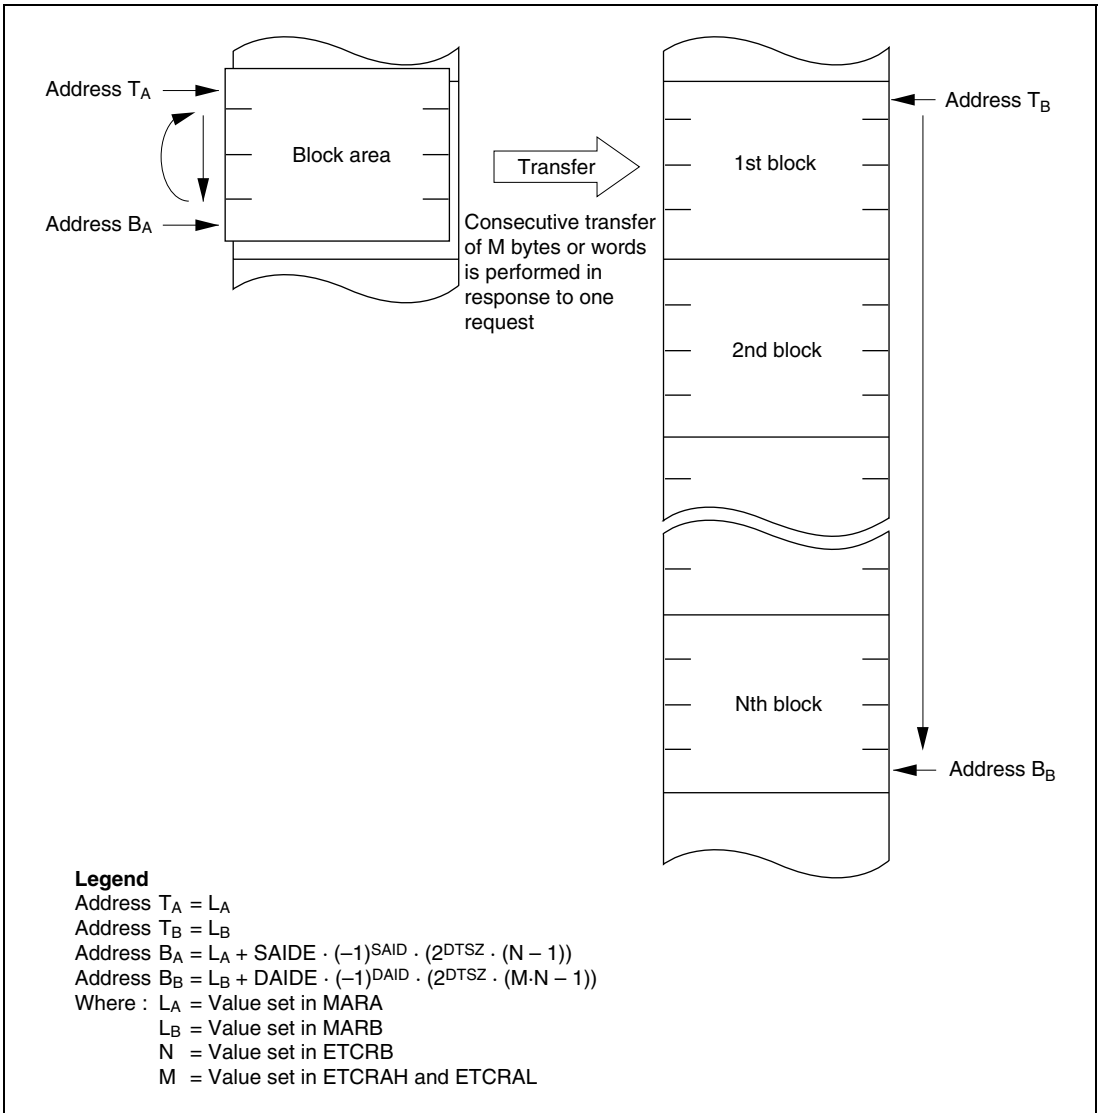

Figure 7.14 Operation in Block Transfer Mode (BLKDIR = 1)

ETCRAL is decremented by 1 each time a byte or word transfer is performed. In response to a single transfer request, burst transfer is performed until the value in ETCRAL reaches H'00. ETCRAL is then loaded with the value in ETCRAH. At this time, the value in the MAR register for which a block designation has been given by the BLKDIR bit in DMACRA is restored in accordance with the DTSZ, SAID/DAID, and SAIDE/DAIDE bits in DMACR.

ETCRB is decremented by 1 after every block transfer, and when the count reaches H'0000 the DTE bit in DMABCRL is cleared and transfer ends. If the DTIE bit in DMABCRL is set to 1 at this point, an interrupt request is sent to the CPU or DTC.

Figure 7.15 shows the operation flow in block transfer mode.

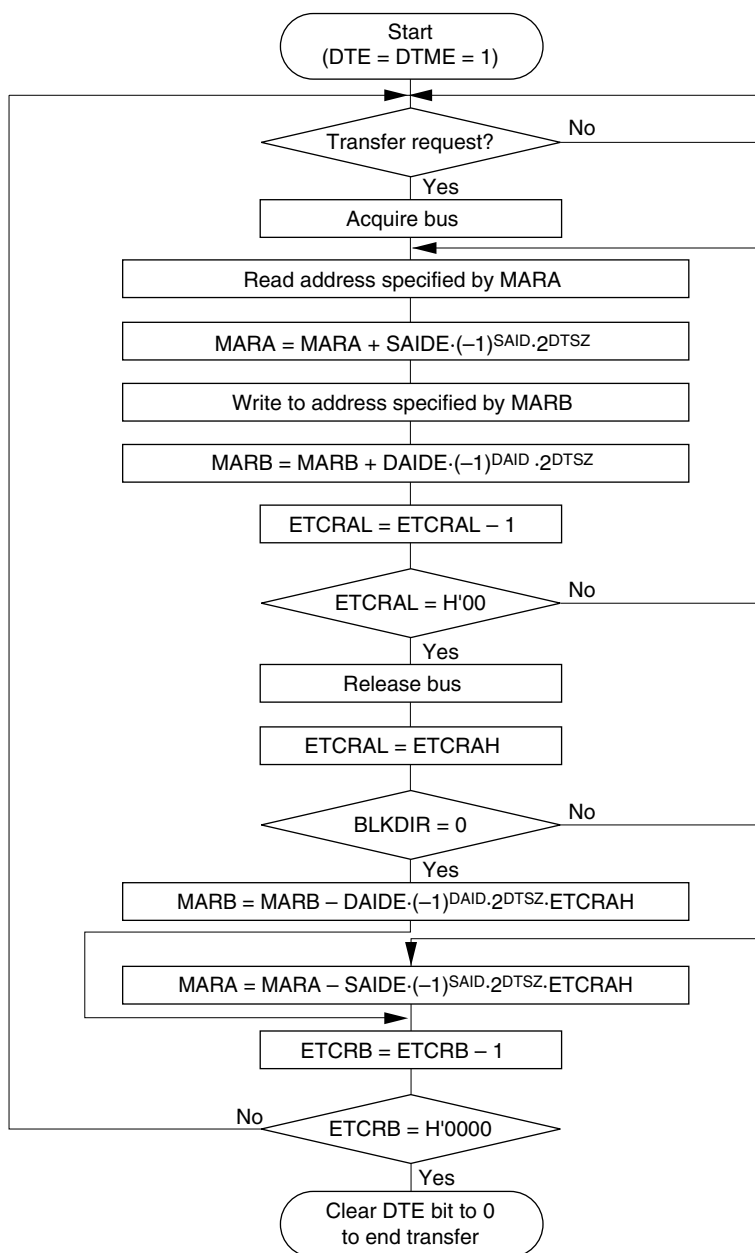

Figure 7.15 Operation Flow in Block Transfer Mode

Transfer requests (activation sources) consist of A/D converter conversion end interrupts, external requests, SCI transmission complete and reception complete interrupts, and TPU channel 0 to 5 compare match/input capture A interrupts.

Figure 7.16 shows an example of the setting procedure for block transfer mode.

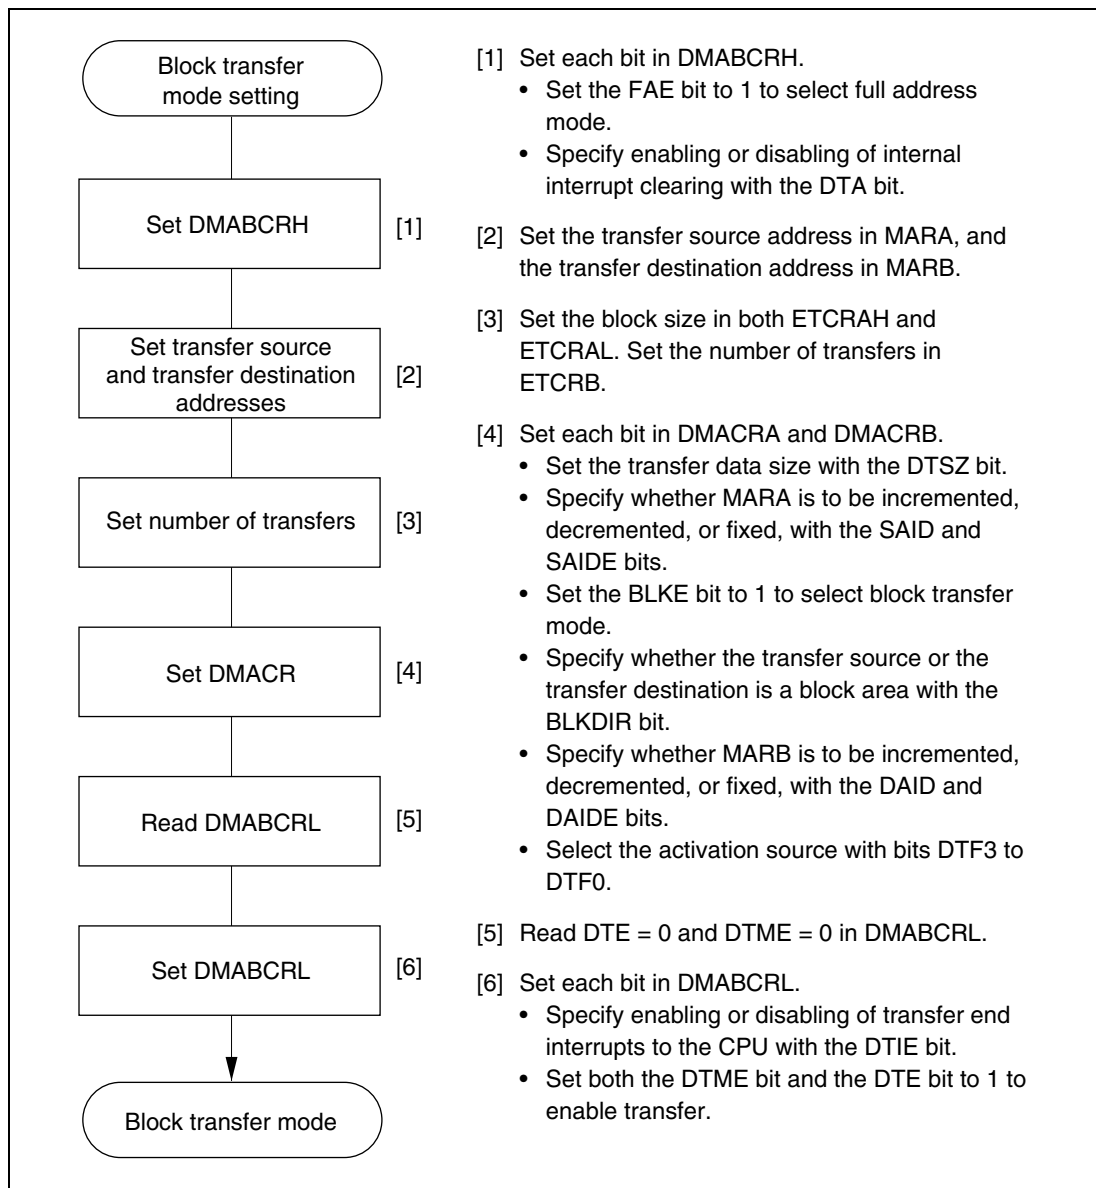

Figure 7.16 Example of Block Transfer Mode Setting Procedure

7.5.8 Basic Bus Cycles

An example of the basic DMAC bus cycle timing is shown in figure 7.17. In this example, word-size transfer is performed from 16-bit, 2-state access space to 8-bit, 3-state access space. When the bus is transferred from the CPU to the DMAC, a source address read and destination address write are performed. The bus is not released in response to another bus request, etc., between these read and write operations. As like CPU cycles, DMA cycles conform to the bus controller settings.

The address is not output to the external address bus in an access to on-chip memory or an internal I/O register.

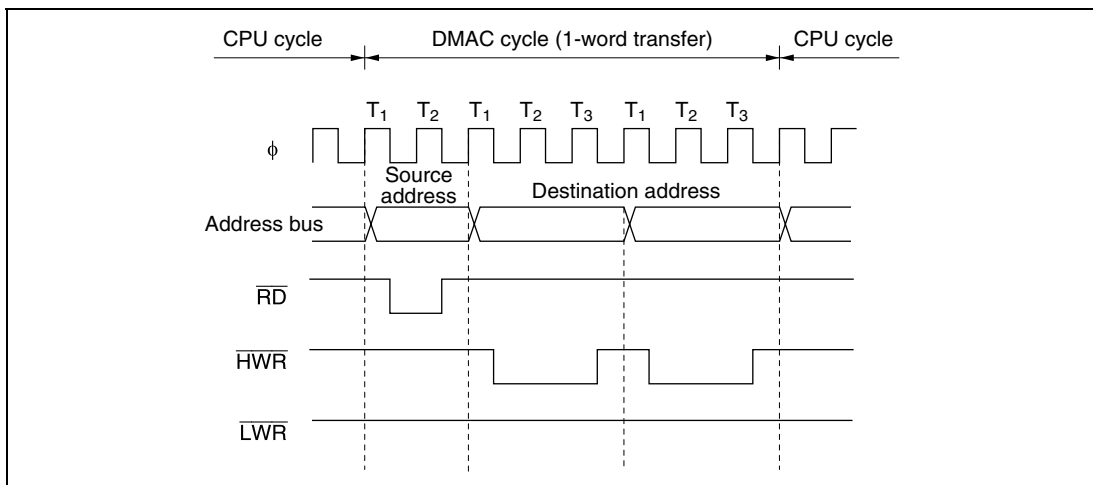

Figure 7.17 Example of DMA Transfer Bus Timing

7.5.9 DMA Transfer (Dual Address Mode) Bus Cycles

Short Address Mode: Figure 7.18 shows a transfer example in which $\overline{\text{TEND}}$ output is enabled and byte-size short address mode transfer (sequential/idle/repeat mode) is performed from external 8-bit, 2-state access space to internal I/O space.

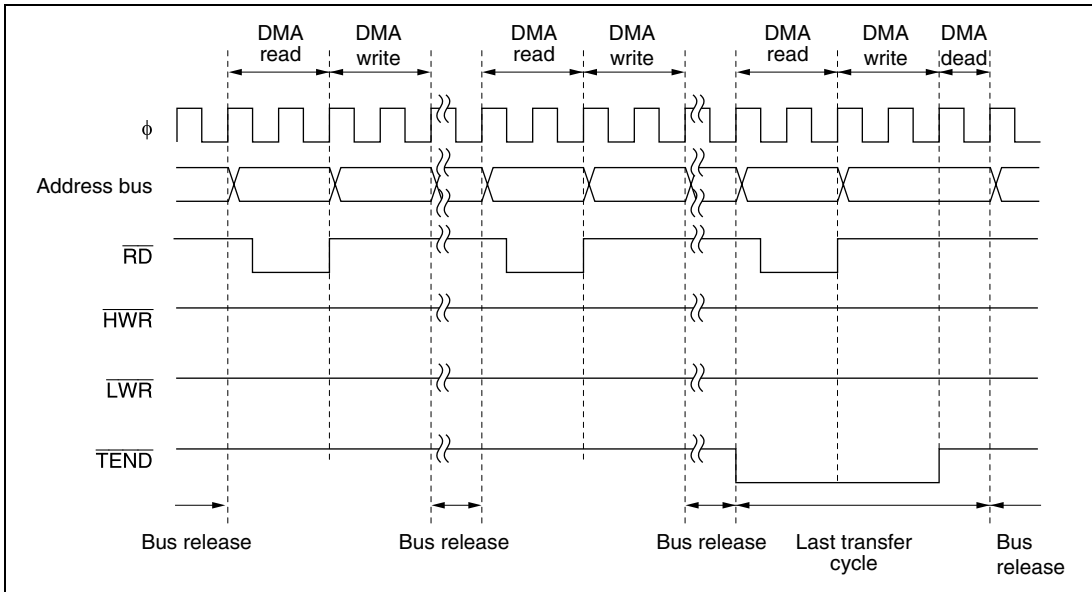

Figure 7.18 Example of Short Address Mode Transfer

A byte or word transfer is performed for a single transfer request, and after the transfer, the bus is released. While the bus is released, one or more bus cycles are executed by the CPU or DTC.

In the transfer end cycle (the cycle in which the transfer counter reaches 0), a one-state DMA dead cycle is inserted after the DMA write cycle.

In repeat mode, when \overline{TEND} output is enabled, \overline{TEND} output goes low in the transfer end cycle.

Full Address Mode (Cycle Steal Mode): Figure 7.19 shows a transfer example in which \overline{TEND} output is enabled and word-size full address mode transfer (cycle steal mode) is performed from external 16-bit, 2-state access space to external 16-bit, 2-state access space.

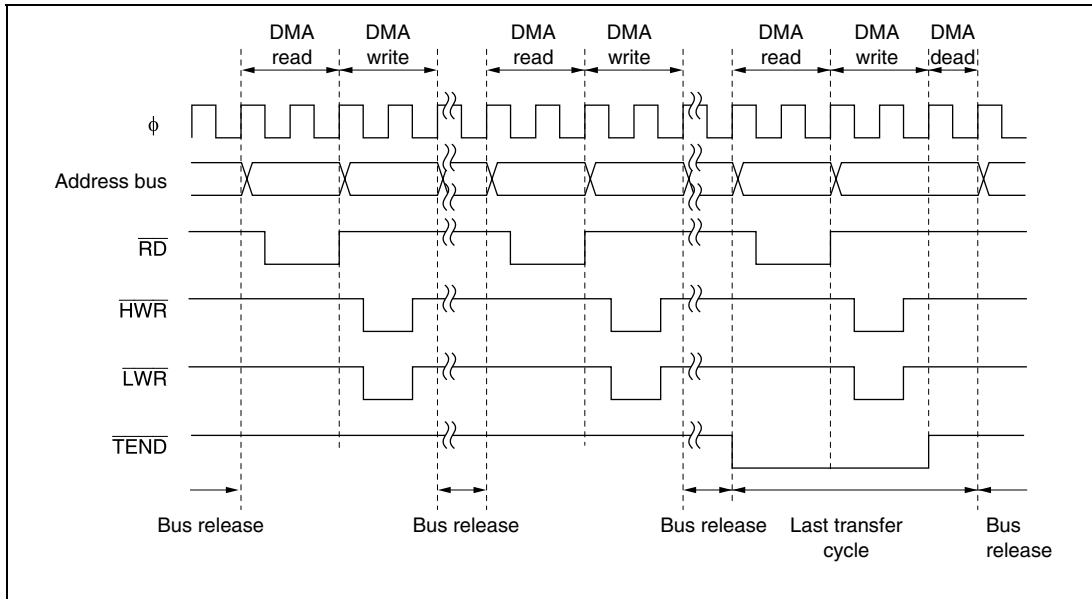

Figure 7.19 Example of Full Address Mode Transfer (Cycle Steal)

A byte or word transfer is performed for a single transfer request, and after the transfer, the bus is released. While the bus is released, one bus cycle is executed by the CPU or DTC.

In the transfer end cycle (the cycle in which the transfer counter reaches 0), a one-state DMA dead cycle is inserted after the DMA write cycle.

Full Address Mode (Burst Mode): Figure 7.20 shows a transfer example in which \overline{TEND} output is enabled and word-size full address mode transfer (burst mode) is performed from external 16-bit, 2-state access space to external 16-bit, 2-state access space.

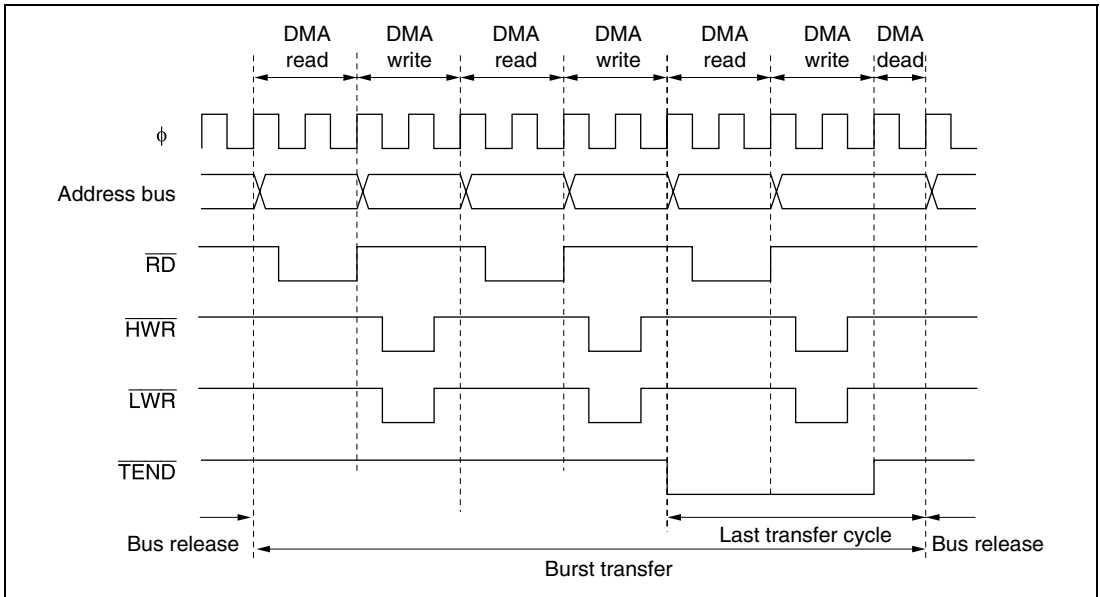

Figure 7.20 Example of Full Address Mode Transfer (Burst Mode)

In burst mode, one-byte or one-word transfers are executed consecutively until transfer ends.

In the transfer end cycle (the cycle in which the transfer counter reaches 0), a one-state DMA dead cycle is inserted after the DMA write cycle.

If a request from another higher-priority channel is generated after burst transfer starts, that channel has to wait until the burst transfer ends.

If an NMI interrupt is generated while a channel designated for burst transfer is in the transfer enabled state, the DTME bit in DMABCRL is cleared and the channel is placed in the transfer disabled state. If burst transfer has already been activated inside the DMAC, the bus is released on completion of a one-byte or one-word transfer within the burst transfer, and burst transfer is suspended. If the last transfer cycle of the burst transfer has already been activated inside the DMAC, execution continues to the end of the transfer even if the DTME bit is cleared.

Full Address Mode (Block Transfer Mode): Figure 7.21 shows a transfer example in which $\overline{\text{TEND}}$ output is enabled and word-size full address mode transfer (block transfer mode) is performed from internal 16-bit, 1-state access space to external 16-bit, 2-state access space.

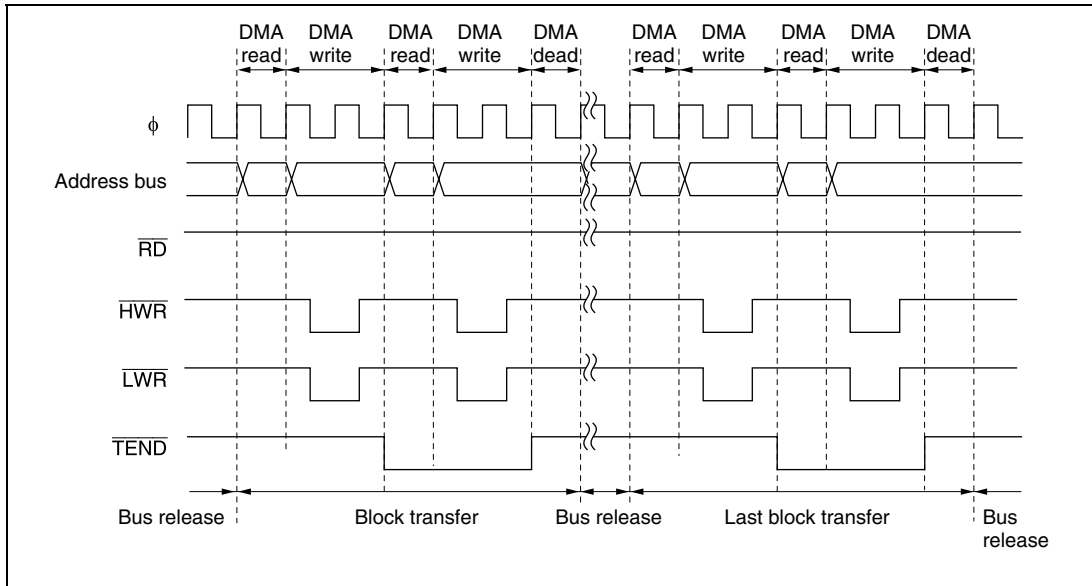

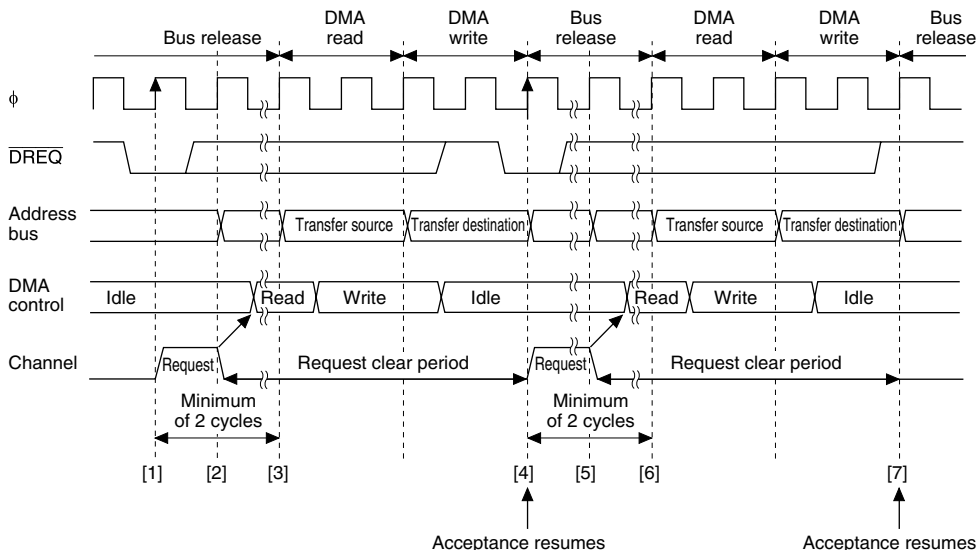

Figure 7.21 Example of Full Address Mode Transfer (Block Transfer Mode)

A one-block transfer is performed for a single transfer request, and after the transfer the bus is released. While the bus is released, one or more bus cycles are executed by the CPU or DTC.

In the transfer end cycle of each block (the cycle in which the transfer counter reaches 0), a one-state DMA dead cycle is inserted after the DMA write cycle. Even if an NMI interrupt is generated during data transfer, block transfer operation is not affected until data transfer for one block has ended.

DREQ Pin Falling Edge Activation Timing: Set the DTA bit in DMABCRH to 1 for the channel for which the \overline{DREQ} pin is selected.

Figure 7.22 shows an example of normal mode transfer activated by the \overline{DREQ} pin falling edge.

- [1] Acceptance after transfer enabling; the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.
- [2] [5] The request is cleared at the next bus break, and activation is started in the DMAC.
- [3] [6] Start of DMA cycle; $\overline{\text{DREQ}}$ pin high level sampling on the rising edge of ϕ starts.
- [4] [7] When the $\overline{\text{DREQ}}$ pin high level has been sampled, acceptance is resumed after the write cycle is completed.
- (As in [1], the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.)

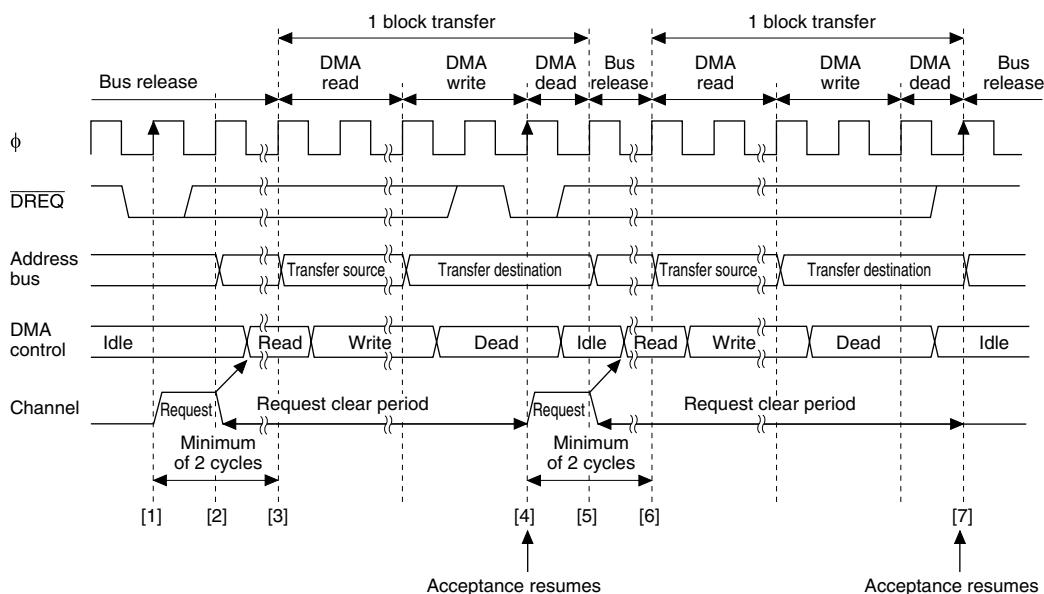

Note: In write data buffer mode, bus breaks from [2] to [7] may be hidden, and not visible.

Figure 7.22 Example of $\overline{\text{DREQ}}$ Pin Falling Edge Activated Normal Mode Transfer

$\overline{\text{DREQ}}$ pin sampling is performed every cycle, with the rising edge of the next ϕ cycle after the end of the DMABCR write cycle for setting the transfer enabled state as the starting point.

When the $\overline{\text{DREQ}}$ pin low level is sampled while acceptance by means of the $\overline{\text{DREQ}}$ pin is possible, the request is held in the DMAC. Then, when activation is initiated in the DMAC, the request is cleared, and $\overline{\text{DREQ}}$ pin high level sampling for edge detection is started. If $\overline{\text{DREQ}}$ pin high level sampling has been completed by the time the DMA write cycle ends, acceptance resumes after the end of the write cycle, $\overline{\text{DREQ}}$ pin low level sampling is performed again, and this operation is repeated until the transfer ends.

Figure 7.23 shows an example of block transfer mode transfer activated by the $\overline{\text{DREQ}}$ pin falling edge.

- [1] Acceptance after transfer enabling; the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.
- [2] [5] The request is cleared at the next bus break, and activation is started in the DMAC.
- [3] [6] Start of DMA cycle; $\overline{\text{DREQ}}$ pin high level sampling on the rising edge of ϕ starts.
- [4] [7] When the $\overline{\text{DREQ}}$ pin high level has been sampled, acceptance is resumed after the dead cycle is completed.
(As in [1], the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.)

Note: In write data buffer mode, bus breaks from [2] to [7] may be hidden, and not visible.

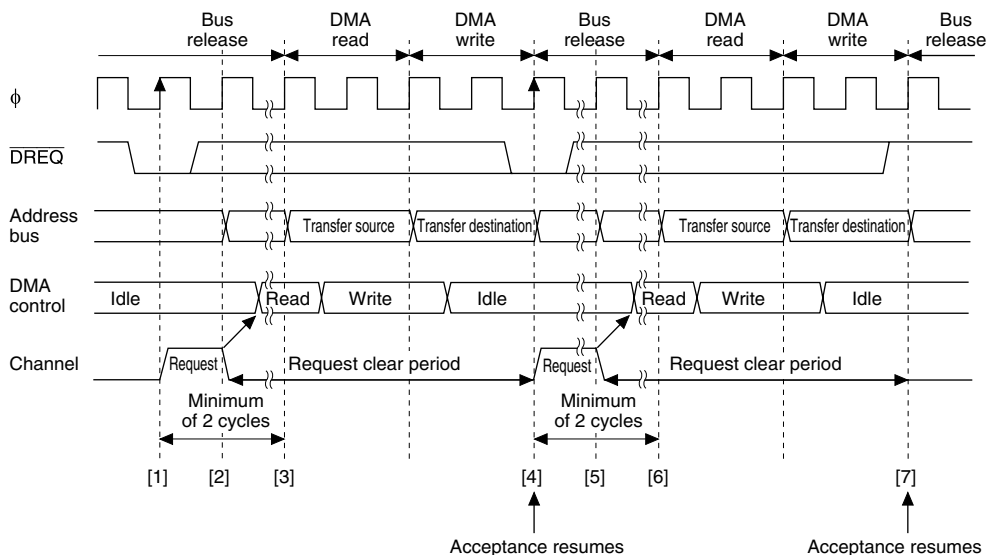

Figure 7.23 Example of $\overline{\text{DREQ}}$ Pin Falling Edge Activated Block Transfer Mode Transfer

$\overline{\text{DREQ}}$ pin sampling is performed every cycle, with the rising edge of the next ϕ cycle after the end of the DMABCR write cycle for setting the transfer enabled state as the starting point.

When the $\overline{\text{DREQ}}$ pin low level is sampled while acceptance by means of the $\overline{\text{DREQ}}$ pin is possible, the request is held in the DMAC. Then, when activation is initiated in the DMAC, the request is cleared, and $\overline{\text{DREQ}}$ pin high level sampling for edge detection is started. If $\overline{\text{DREQ}}$ pin high level sampling has been completed by the time the DMA dead cycle ends, acceptance resumes after the end of the dead cycle, $\overline{\text{DREQ}}$ pin low level sampling is performed again, and this operation is repeated until the transfer ends.

$\overline{\text{DREQ}}$ Pin Low Level Activation Timing (Normal Mode): Set the DTA bit in DMABCRH to 1 for the channel for which the $\overline{\text{DREQ}}$ pin is selected.

Figure 7.24 shows an example of normal mode transfer activated by the $\overline{\text{DREQ}}$ pin low level.

- [1] Acceptance after transfer enabling; the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.
- [2] [5] The request is cleared at the next bus break, and activation is started in the DMAC.
- [3] [6] The DMA cycle is started.
- [4] [7] Acceptance is resumed after the write cycle is completed.
(As in [1], the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.)

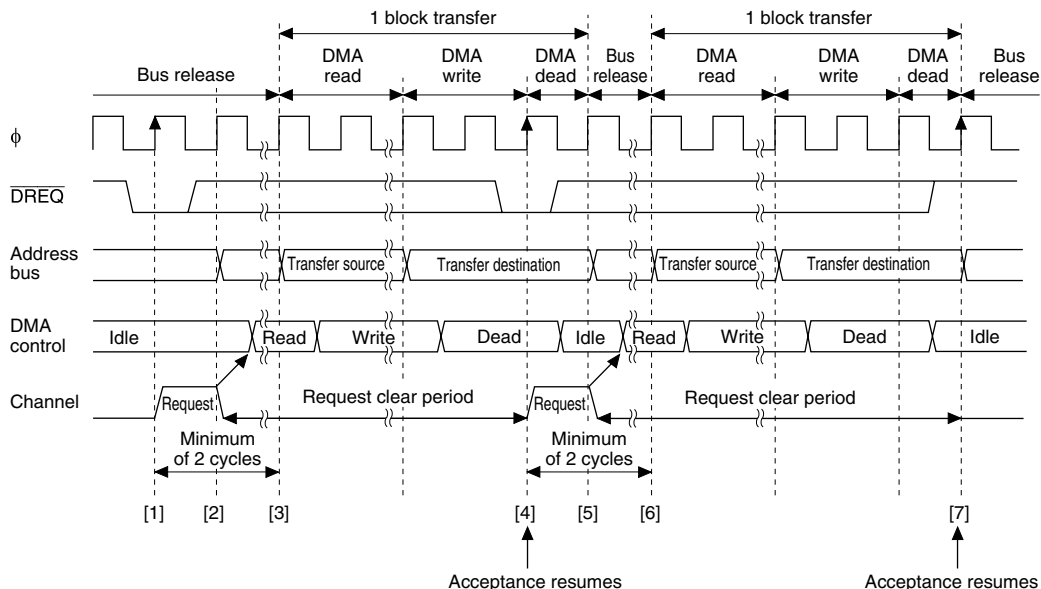

Note: In write data buffer mode, bus breaks from [2] to [7] may be hidden, and not visible.

Figure 7.24 Example of $\overline{\text{DREQ}}$ Pin Low Level Activated Normal Mode Transfer

$\overline{\text{DREQ}}$ pin sampling is performed every cycle, with the rising edge of the next ϕ cycle after the end of the DMABCR write cycle for setting the transfer enabled state as the starting point.

When the $\overline{\text{DREQ}}$ pin low level is sampled while acceptance by means of the $\overline{\text{DREQ}}$ pin is possible, the request is held in the DMAC. Then, when activation is initiated in the DMAC, the request is cleared. After the end of the write cycle, acceptance resumes, $\overline{\text{DREQ}}$ pin low level sampling is performed again, and this operation is repeated until the transfer ends.

Figure 7.25 shows an example of block transfer mode transfer activated by $\overline{\text{DREQ}}$ pin low level.

- [1] Acceptance after transfer enabling; the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.
- [2] [5] The request is cleared at the next bus break, and activation is started in the DMAC.
- [3] [6] The DMA cycle is started.
- [4] [7] Acceptance is resumed after the dead cycle is completed.
(As in [1], the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.)

Note: In write data buffer mode, bus breaks from [2] to [7] may be hidden, and not visible.

Figure 7.25 Example of $\overline{\text{DREQ}}$ Pin Low Level Activated Block Transfer Mode Transfer

$\overline{\text{DREQ}}$ pin sampling is performed every cycle, with the rising edge of the next ϕ cycle after the end of the DMABCR write cycle for setting the transfer enabled state as the starting point.

When the $\overline{\text{DREQ}}$ pin low level is sampled while acceptance by means of the $\overline{\text{DREQ}}$ pin is possible, the request is held in the DMAC. Then, when activation is initiated in the DMAC, the request is cleared. After the end of the dead cycle, acceptance resumes, $\overline{\text{DREQ}}$ pin low level sampling is performed again, and this operation is repeated until the transfer ends.

7.5.10 DMA Transfer (Single Address Mode) Bus Cycles

Single Address Mode (Read): Figure 7.26 shows a transfer example in which $\overline{\text{TEND}}$ output is enabled and byte-size single address mode transfer (read) is performed from external 8-bit, 2-state access space to an external device.

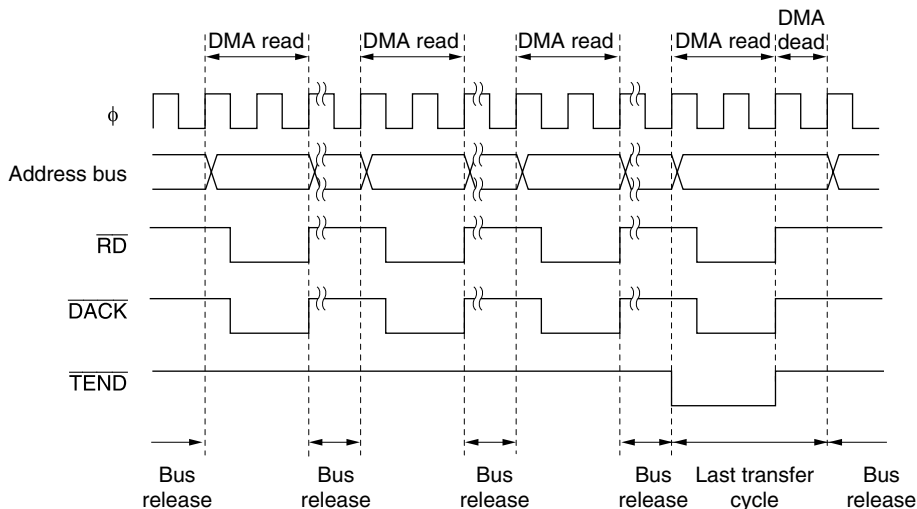

Figure 7.26 Example of Single Address Mode Transfer (Byte Read)

Figure 7.27 shows a transfer example in which \overline{TEND} output is enabled and word-size single address mode transfer (read) is performed from external 8-bit, 2-state access space to an external device.

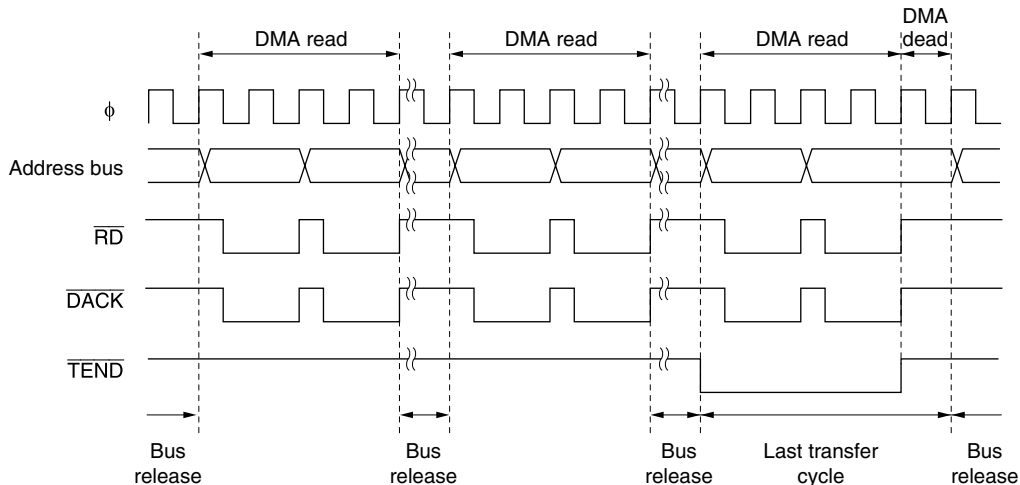

Figure 7.27 Example of Single Address Mode (Word Read) Transfer

A byte or word transfer is performed for a single transfer request, and after the transfer, the bus is released. While the bus is released, one or more bus cycles are executed by the CPU or DTC.

In the transfer end cycle (the cycle in which the transfer counter reaches 0), a one-state DMA dead cycle is inserted after the DMA write cycle.

Single Address Mode (Write): Figure 7.28 shows a transfer example in which $\overline{\text{TEND}}$ output is enabled and byte-size single address mode transfer (write) is performed from an external device to external 8-bit, 2-state access space.

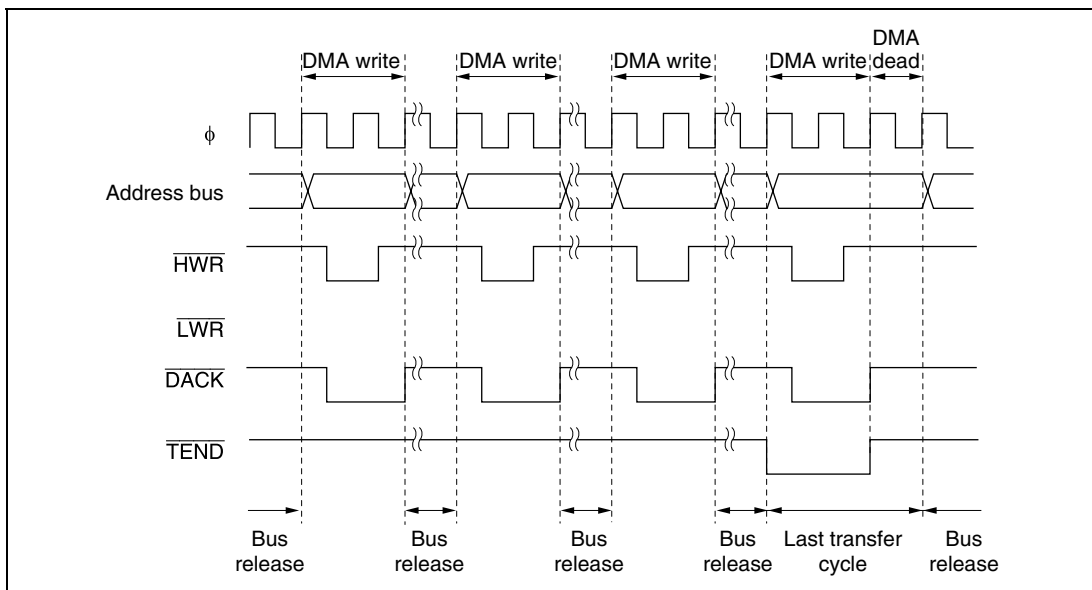

Figure 7.28 Example of Single Address Mode Transfer (Byte Write)

Figure 7.29 shows a transfer example in which $\overline{\text{TEND}}$ output is enabled and word-size single address mode transfer (write) is performed from an external device to external 8-bit, 2-state access space.

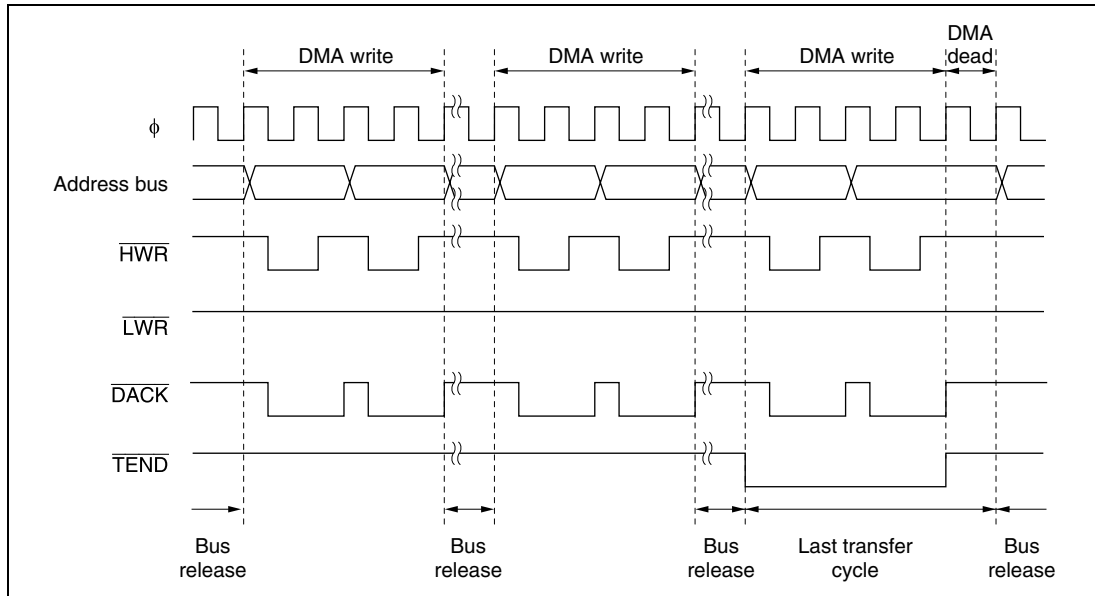

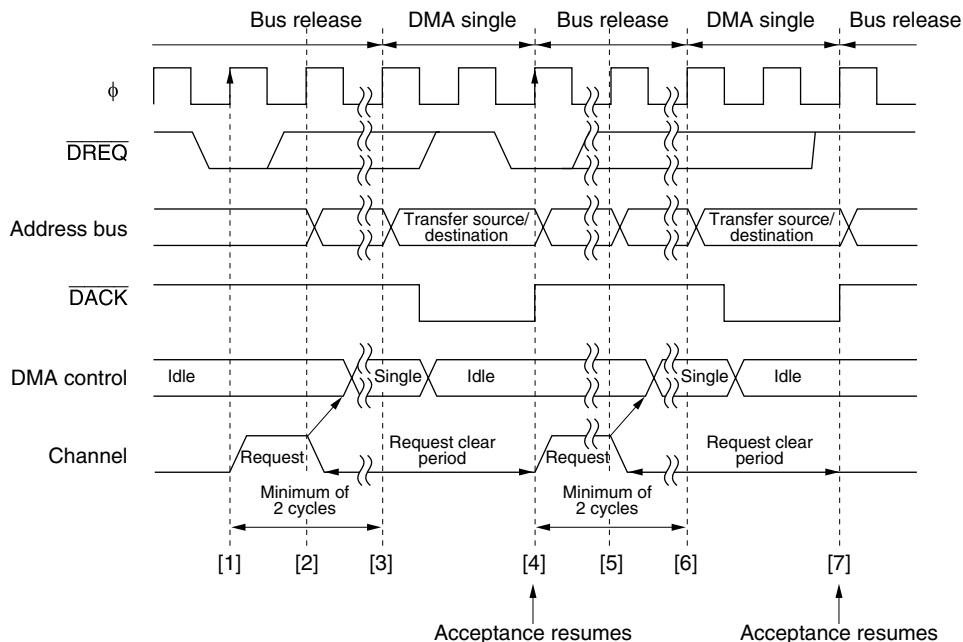

Figure 7.29 Example of Single Address Mode Transfer (Word Write)

A byte or word transfer is performed for a single transfer request, and after the transfer, the bus is released. While the bus is released, one or more bus cycles are executed by the CPU or DTC.

In the transfer end cycle (the cycle in which the transfer counter reaches 0), a one-state DMA dead cycle is inserted after the DMA write cycle.

DREQ Pin Falling Edge Activation Timing: Set the DTA bit in DMABCRH to 1 for the channel for which the DREQ pin is selected.

Figure 7.30 shows an example of single address mode transfer activated by the DREQ pin falling edge.

- [1] Acceptance after transfer enabling; the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.
- [2] [5] The request is cleared at the next bus break, and activation is started in the DMAC.
- [3] [6] Start of DMA cycle; $\overline{\text{DREQ}}$ pin high level sampling on the rising edge of ϕ starts.
- [4] [7] When the $\overline{\text{DREQ}}$ pin high level has been sampled, acceptance is resumed after the single cycle is completed. (As in [1], the $\overline{\text{DREQ}}$ pin low level is sampled on the rising edge of ϕ , and the request is held.)

Note: In write data buffer mode, bus breaks from [2] to [7] may be hidden, and not visible.

Figure 7.30 Example of $\overline{\text{DREQ}}$ Pin Falling Edge Activated Single Address Mode Transfer

$\overline{\text{DREQ}}$ pin sampling is performed every cycle, with the rising edge of the next ϕ cycle after the end of the DMABCR write cycle for setting the transfer enabled state as the starting point.

When the $\overline{\text{DREQ}}$ pin low level is sampled while acceptance by means of the $\overline{\text{DREQ}}$ pin is possible, the request is held in the DMAC. Then, when activation is initiated in the DMAC, the request is cleared, and $\overline{\text{DREQ}}$ pin high level sampling for edge detection is started. If $\overline{\text{DREQ}}$ pin high level sampling has been completed by the time the DMA single cycle ends, acceptance resumes after the end of the single cycle, $\overline{\text{DREQ}}$ pin low level sampling is performed again, and this operation is repeated until the transfer ends.

$\overline{\text{DREQ}}$ Pin Low Level Activation Timing: Set the DTA bit in DMABCRH to 1 for the channel for which the $\overline{\text{DREQ}}$ pin is selected.

Figure 7.31 shows an example of single address mode transfer activated by the $\overline{\text{DREQ}}$ pin low level.

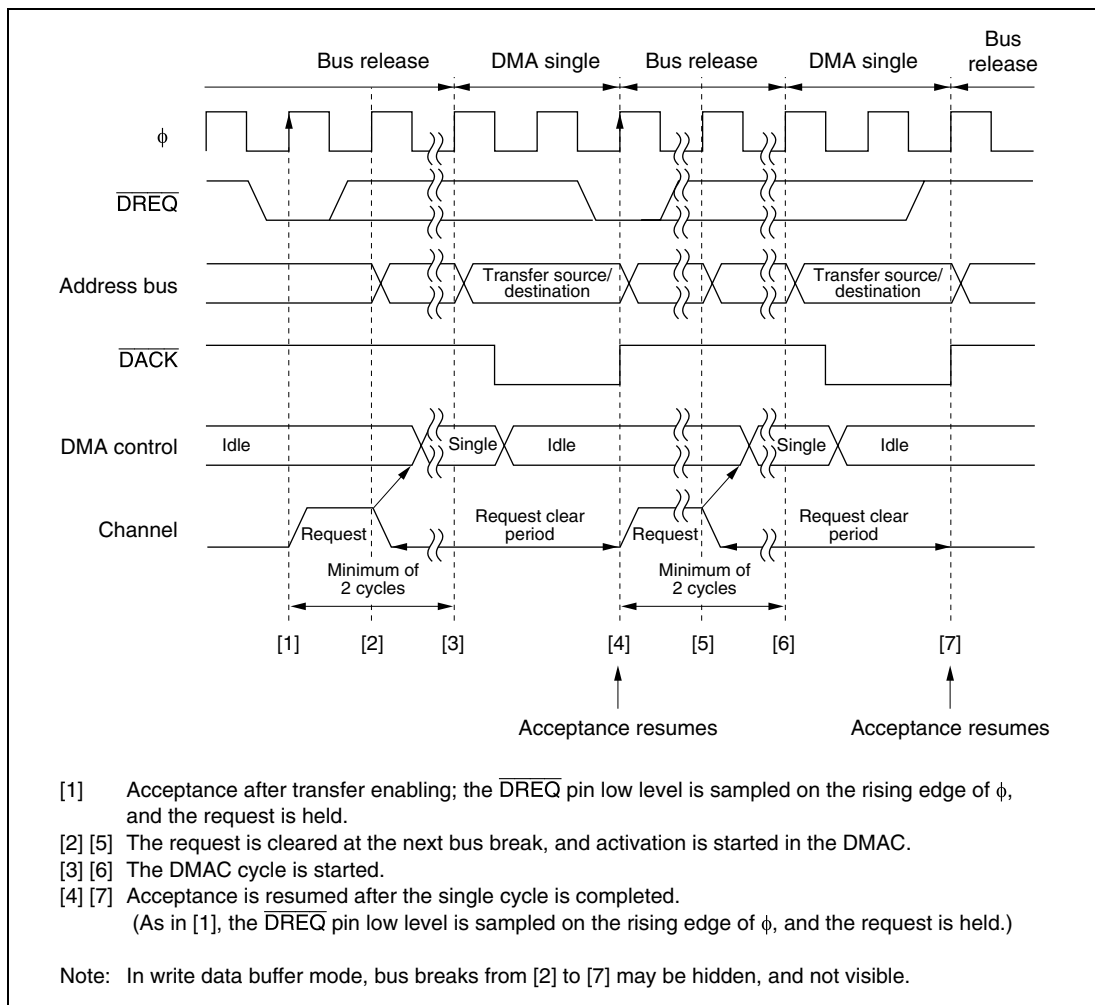

Figure 7.31 Example of $\overline{\text{DREQ}}$ Pin Low Level Activated Single Address Mode Transfer

$\overline{\text{DREQ}}$ pin sampling is performed every cycle, with the rising edge of the next ϕ cycle after the end of the DMABCR write cycle for setting the transfer enabled state as the starting point.

When the $\overline{\text{DREQ}}$ pin low level is sampled while acceptance by means of the $\overline{\text{DREQ}}$ pin is possible, the request is held in the DMAC. Then, when activation is initiated in the DMAC, the request is cleared. After the end of the single cycle, acceptance resumes, $\overline{\text{DREQ}}$ pin low level sampling is performed again, and this operation is repeated until the transfer ends.

7.5.11 Write Data Buffer Function

DMAC internal-to-external dual address transfers and single address transfers can be executed at high speed using the write data buffer function, enabling system throughput to be improved.

When the WDBE bit of BCR in the bus controller is set to 1, enabling the write data buffer function, external write cycles in dual address transfers or single address transfers are executed in parallel with internal accesses (on-chip memory or internal I/O registers). Internal accesses are independent of the bus master, and DMAC dead cycles are regarded as internal accesses.

A low level can always be output from the $\overline{\text{TEND}}$ pin if the bus cycle in which a low level is to be output from the $\overline{\text{TEND}}$ pin is an external bus cycle. However, a low level is not output from the $\overline{\text{TEND}}$ pin if the bus cycle in which a low level is to be output from the $\overline{\text{TEND}}$ pin is an internal bus cycle, and an external write cycle is executed in parallel with this cycle.

Figure 7.32 shows an example of dual address transfer using the write data buffer function. In this example, burst mode transfer from on-chip RAM to external memory is performed.

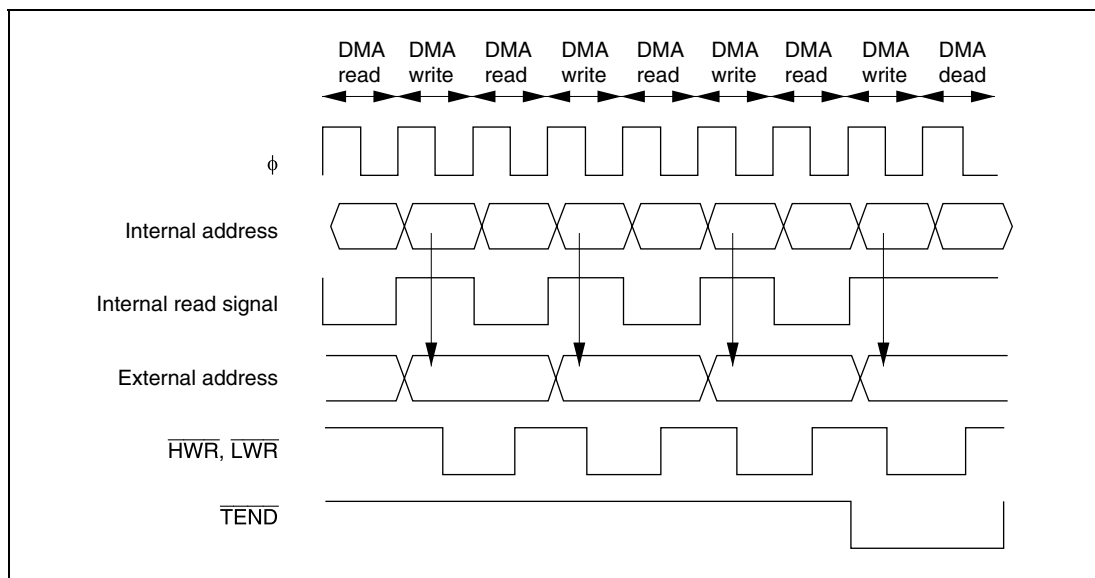

Figure 7.32 Example of Dual Address Transfer Using Write Data Buffer Function

Figure 7.33 shows an example of single address transfer using the write data buffer function. In this example, the CPU program area is in on-chip memory.

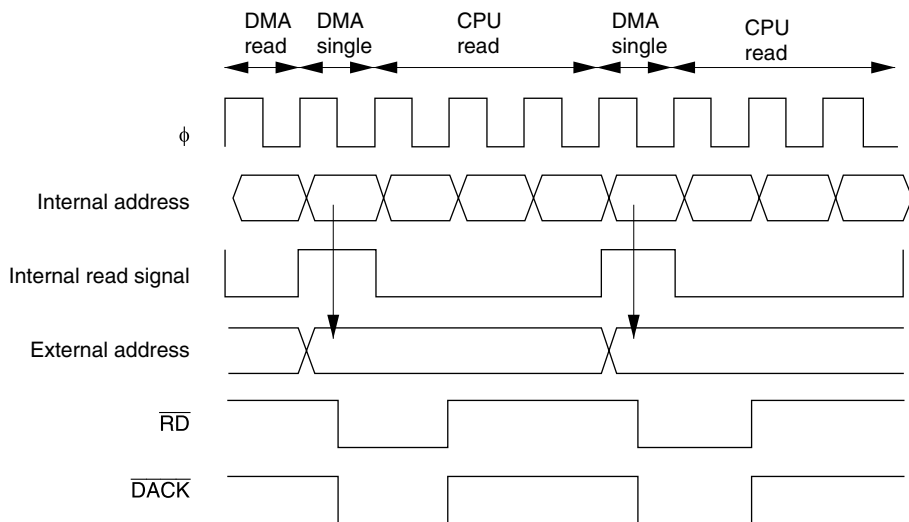

Figure 7.33 Example of Single Address Transfer Using Write Data Buffer Function

When the write data buffer function is activated, the DMAC recognizes that the bus cycle concerned has ended, and starts the next operation. Therefore, $\overline{\text{DREQ}}$ pin sampling is started one state after the start of the DMA write cycle or single address transfer.

7.5.12 Multi-Channel Operation

The DMAC channel priority order is: channel 0 > channel 1, and channel A > channel B. Table 7.11 summarizes the priority order for DMAC channels.

Table 7.11 DMAC Channel Priority Order

Short Address Mode	Full Address Mode	Priority
Channel 0A	Channel 0	High
Channel 0B		
Channel 1A	Channel 1	
Channel 1B		Low

If transfer requests are issued simultaneously for more than one channel, or if a transfer request for another channel is issued during a transfer, when the bus is released, the DMAC selects the highest-priority channel from among those issuing a request according to the priority order shown in table 7.11. During burst transfer, or when one block is being transferred in block transfer, the channel will not be changed until the end of the transfer. Figure 7.34 shows a transfer example in which transfer requests are issued simultaneously for channels 0A, 0B, and 1.

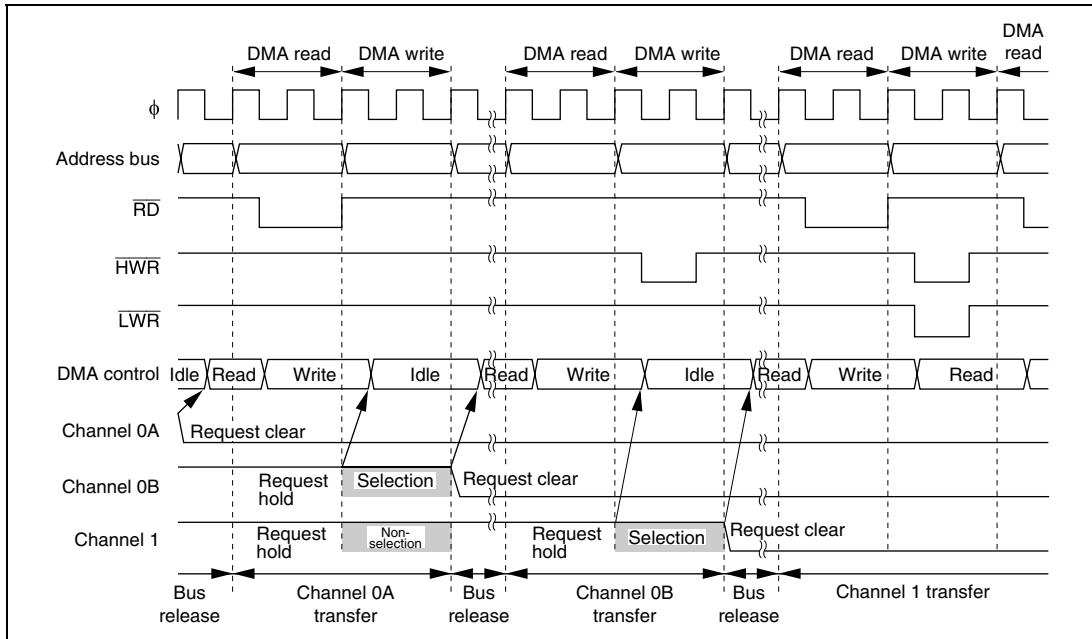

Figure 7.34 Example of Multi-Channel Transfer

7.5.13 Relation between DMAC and External Bus Requests and Refresh Cycles

When the DMAC accesses external space, conflict with a refresh cycle or external bus release cycle may arise. In this case, the bus controller will suspend the transfer and insert a refresh cycle or external bus release cycle, in accordance with the external bus priority order, even if the DMAC is executing a burst transfer or block transfer. (An external access by the DTC or CPU, which has a lower priority than the DMAC, is not executed until the DMAC releases the external bus.)

When the DMAC transfer mode is dual address mode, the DMAC releases the external bus after an external write cycle. The external read cycle and external write cycle are inseparable, and so the bus cannot be released between these two cycles.

When the DMAC accesses internal space (on-chip memory or an internal I/O register), the DMAC cycle may be executed at the same time as a refresh cycle or external bus release cycle.

7.5.14 DMAC and NMI Interrupts

When an NMI interrupt is requested, burst mode transfer in full address mode is interrupted. An NMI interrupt does not affect the operation of the DMAC in other modes.

In full address mode, transfer is enabled for a channel when both the DTE bit and DTME bit are set to 1. With burst mode setting, the DTME bit is cleared when an NMI interrupt is requested.

If the DTME bit is cleared during burst mode transfer, the DMAC discontinues transfer on completion of the 1-byte or 1-word transfer in progress, then releases the bus, which passes to the CPU.

The channel on which transfer was interrupted can be restarted by setting the DTME bit to 1 again. Figure 7.35 shows the procedure for continuing transfer when it has been interrupted by an NMI interrupt on a channel designated for burst mode transfer.

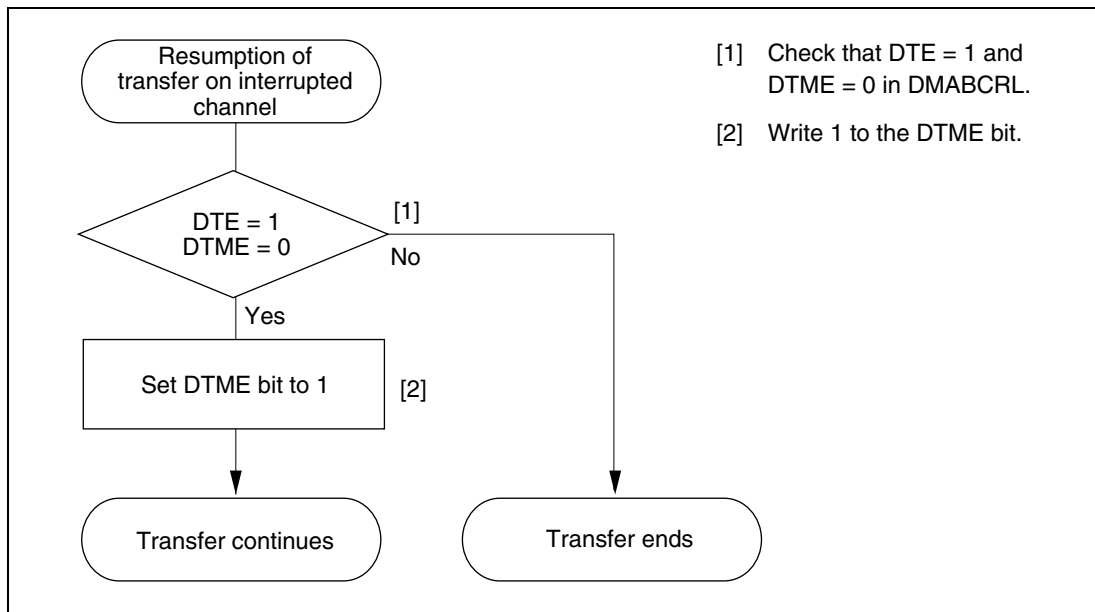

Figure 7.35 Example of Procedure for Continuing Transfer on Channel Interrupted by NMI Interrupt

7.5.15 Forced Termination of DMAC Operation

If the DTE bit in DMABCRL is cleared to 0 for the channel currently operating, the DMAC stops on completion of the 1-byte or 1-word transfer in progress. DMAC operation resumes when the DTE bit is set to 1 again. In full address mode, the same applies to the DTME bit in DMABCRL. Figure 7.36 shows the procedure for forcibly terminating DMAC operation by software.

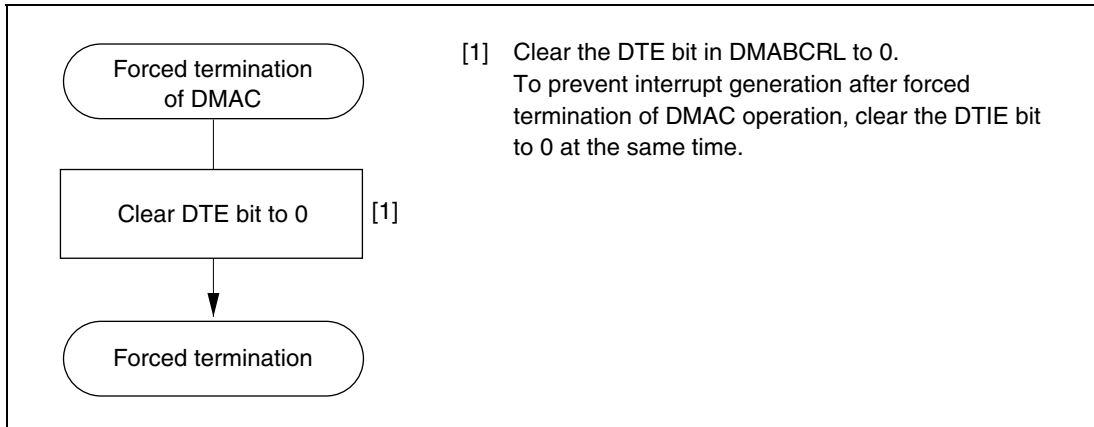

Figure 7.36 Example of Procedure for Forcibly Terminating DMAC Operation

7.5.16 Clearing Full Address Mode

Figure 7.37 shows the procedure for releasing and initializing a channel designated for full address mode. After full address mode has been cleared, the channel can be set to another transfer mode using the appropriate setting procedure.

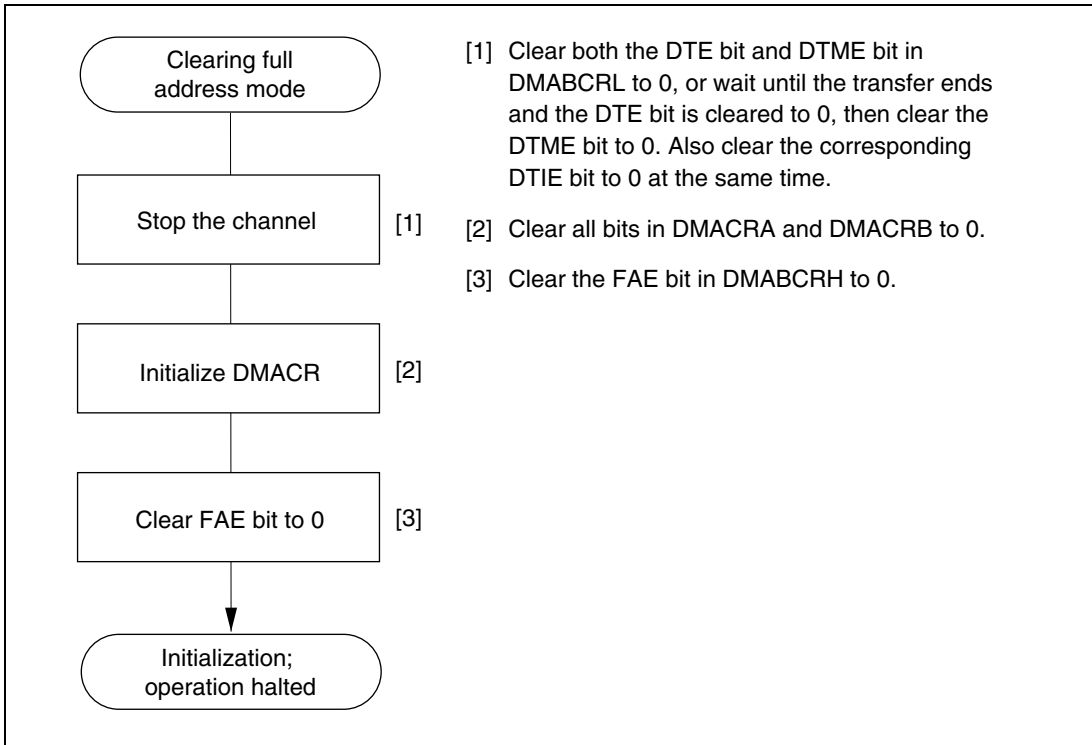

Figure 7.37 Example of Procedure for Clearing Full Address Mode

7.6 Interrupt Sources

The sources of interrupts generated by the DMAC are transfer end and transfer break. Table 7.12 shows the interrupt sources and their priority order.

Table 7.12 Interrupt Sources and Priority Order

Interrupt Name	Interrupt Source		Interrupt Priority Order
	Short Address Mode	Full Address Mode	
DMTEND0A	Interrupt due to end of transfer on channel 0A	Interrupt due to end of transfer on channel 0	<div style="text-align: center;"> High ↑ Low </div>
DMTEND0B	Interrupt due to end of transfer on channel 0B	Interrupt due to break in transfer on channel 0	
DMTEND1A	Interrupt due to end of transfer on channel 1A	Interrupt due to end of transfer on channel 1	
DMTEND1B	Interrupt due to end of transfer on channel 1B	Interrupt due to break in transfer on channel 1	

Enabling or disabling of each interrupt source is set by means of the DTIE bit in DMABCRL for the corresponding channel in DMABCRL, and interrupts from each source are sent to the interrupt controller independently. The priority of transfer end interrupts on each channel is decided by the interrupt controller, as shown in table 7.12.

Figure 7.38 shows a block diagram of a transfer end/transfer break interrupt. An interrupt is always generated when the DTIE bit is set to 1 while the DTE bit in DMABCRL is cleared to 0.

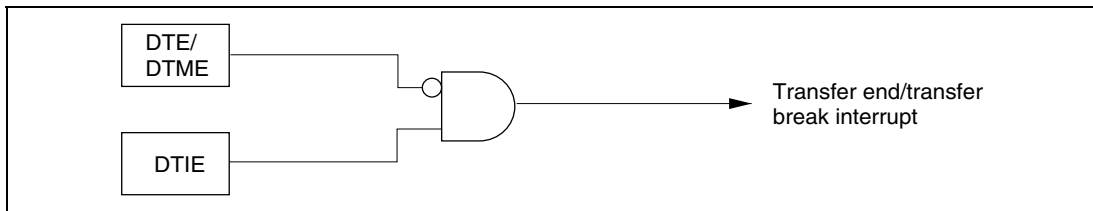

Figure 7.38 Block Diagram of Transfer End/Transfer Break Interrupt

In full address mode, a transfer break interrupt is generated when the DTME bit is cleared to 0 while the DTIEB bit is set to 1. In both short address mode and full address mode, DMABCR should be set so as to prevent the occurrence of a combination that constitutes a condition for interrupt generation during setting.

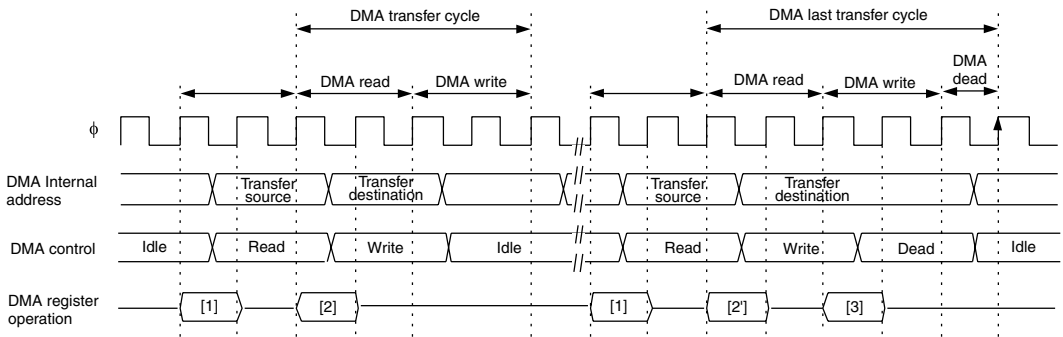

7.7 Usage Notes

7.7.1 DMAC Register Access during Operation

Except for forced termination of the DMAC, the operating (including transfer waiting state) channel setting should not be changed. The operating channel setting should only be changed when transfer is disabled. Also, DMAC registers should not be written to in a DMA transfer.

DMAC register reads during operation (including the transfer waiting state) are described below.

- DMAC control starts one cycle before the bus cycle, with output of the internal address. Consequently, MAR is updated in the bus cycle before DMA transfer. Figure 7.39 shows an example of the update timing for DMAC registers in dual address transfer mode.

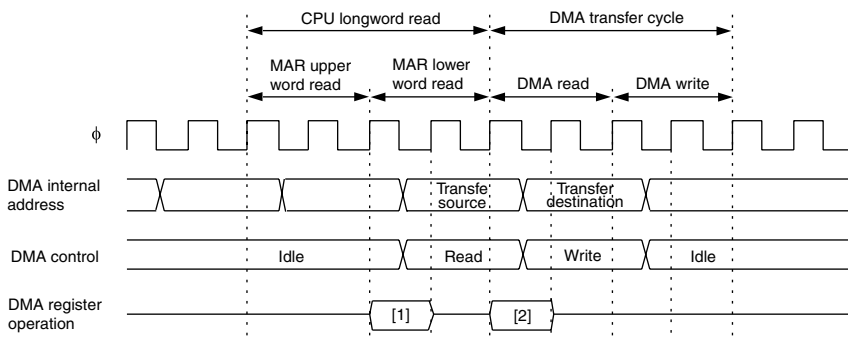

- [1] Transfer source address register MAR operation (incremented/decremented/fixed)
Transfer counter ETCR operation (decremented)
Block size counter ETCR operation (decremented in block transfer mode)
- [2] Transfer destination address register MAR operation (incremented/decremented/fixed)
- [2'] Transfer destination address register MAR operation (incremented/decremented/fixed)
Block transfer counter ETCR operation (decremented, in last transfer cycle of a block in block transfer mode)
- [3] Transfer address register MAR restore operation (in block or repeat transfer mode)
Transfer counter ETCR restore (in repeat transfer mode)
Block size counter ETCR restore (in block transfer mode)

Note: In single address transfer mode, the update timing is the same as [1].
The MAR operation is post-incrementing/decrementing of the DMA internal address value.

Figure 7.39 DMAC Register Update Timing

- If a DMAC transfer cycle occurs immediately after a DMAC register read cycle, the DMAC register is read as shown in figure 7.40.

Note: The lower word of MAR is the updated value after the operation in [1].

Figure 7.40 Contention between DMAC Register Update and CPU Read

7.7.2 Module Stop

When the MSTP13 bit in MSTPCR is set to 1, the DMAC clock stops, and the module stop state is entered. However, 1 cannot be written to the MSTP13 bit if any of the DMAC channels is enabled. This setting should therefore be made when DMAC operation is stopped.

When the DMAC clock stops, DMAC register accesses can no longer be made. Since the following DMAC register settings are valid even in the module stop state, they should be invalidated, if necessary, before a module stop.

- Transfer end/break interrupt (DTE = 0 and DTIE = 1)
- $\overline{\text{TEND}}$ pin enable (TEE = 1)
- $\overline{\text{DACK}}$ pin enable (FAE = 0 and SAE = 1)

7.7.3 Write Data Buffer Function

When the WDBE bit of BCR in the bus controller is set to 1, enabling the write data buffer function, external write cycles in dual address transfers or single address transfers are executed in parallel with internal accesses (on-chip memory or internal I/O registers).

- Write data buffer function and DMAC register setting

If the setting of a register that controls external accesses is changed during execution of an external access by means of the write data buffer function, the external access may not be performed normally. Registers that control external accesses should only be manipulated when external reads, etc., are used with DMAC operation disabled, and the operation is not performed in parallel with external access.

- Write data buffer function and DMAC operation timing

The DMAC can start its next operation during external access using the write data buffer function. Consequently, the $\overline{\text{DREQ}}$ pin sampling timing, $\overline{\text{TEND}}$ output timing, etc., are different from the case in which the write data buffer function is disabled. Also, internal bus cycles may be hidden, and not visible.

7.7.4 $\overline{\text{TEND}}$ Output

If the last transfer cycle is for an internal address, note that even if low-level output at the $\overline{\text{TEND}}$ pin has been set, a low level may not be output at the $\overline{\text{TEND}}$ pin under the following external bus conditions since the last transfer cycle (internal bus cycle) and the external bus cycle are executed in parallel.

1. Write cycle with write buffer mode enabled
2. DMAC single address cycle for a different channel with write buffer mode enabled
3. Bus release cycle

4. CBR refresh cycle

Figure 7.41 shows an example in which a low level is not output from the $\overline{\text{TEND}}$ pin in case 2 above.

If the last transfer cycle is an external address cycle, a low level is output at the $\overline{\text{TEND}}$ pin in synchronization with the bus cycle.

However, if the last transfer cycle and a CBR refresh occur simultaneously, note that although the CBR refresh and the last transfer cycle may be executed consecutively, $\overline{\text{TEND}}$ may also go low in this case for the refresh cycle.

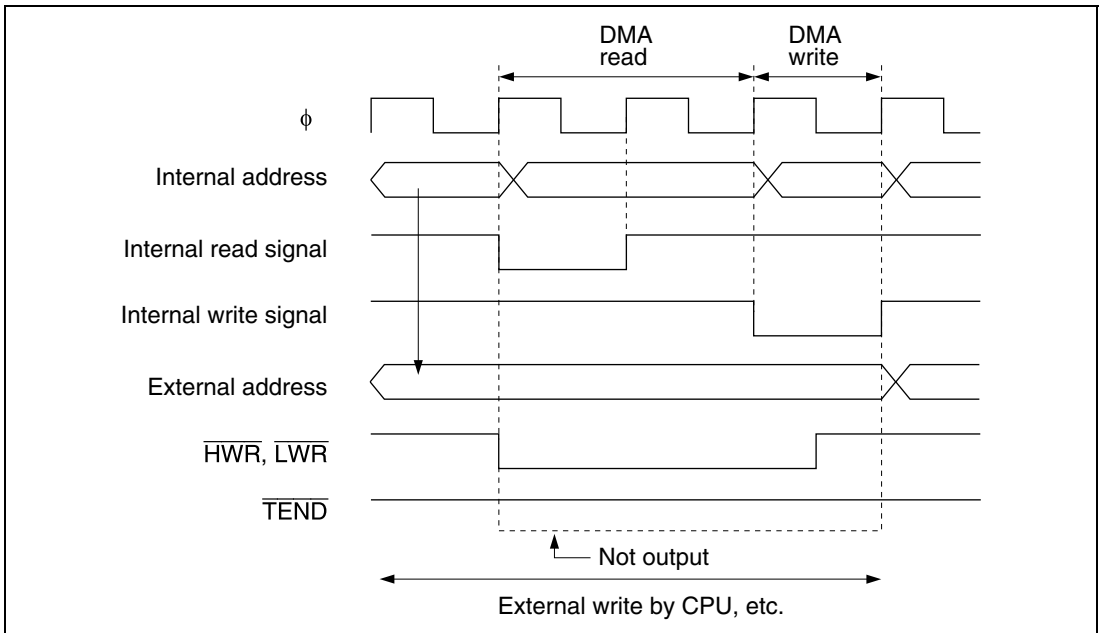

Figure 7.41 Example in which Low Level is Not Output at $\overline{\text{TEND}}$ Pin

7.7.5 Activation by Falling Edge on $\overline{\text{DREQ}}$ Pin

$\overline{\text{DREQ}}$ pin falling edge detection is performed in synchronization with DMAC internal operations. The operation is as follows:

- [1] Activation request wait state: Waits for detection of a low level on the $\overline{\text{DREQ}}$ pin, and switches to [2].
- [2] Transfer wait state: Waits for DMAC data transfer to become possible, and switches to [3].
- [3] Activation request disabled state: Waits for detection of a high level on the $\overline{\text{DREQ}}$ pin, and switches to [1].

After DMAC transfer is enabled, a transition is made to [1]. Thus, initial activation after transfer is enabled is performed on detection of a low level.

7.7.6 Activation Source Acceptance

At the start of activation source acceptance, a low level is detected in both $\overline{\text{DREQ}}$ pin falling edge sensing and low level sensing. Similarly, in the case of an internal interrupt, the interrupt request is detected. Therefore, a request is accepted from an internal interrupt or $\overline{\text{DREQ}}$ pin low level that occurs before write to DMABCRL to enable transfer.

When the DMAC is activated, take any necessary steps to prevent an internal interrupt or $\overline{\text{DREQ}}$ pin low level remaining from the end of the previous transfer, etc.

7.7.7 Internal Interrupt after End of Transfer

When the DTE bit in DMABCRL is cleared to 0 at the end of a transfer or by a forcible termination, the selected internal interrupt request will be sent to the CPU or DTC even if the DTA bit in DMABCRH is set to 1.

Also, if internal DMAC activation has already been initiated when operation is forcibly terminated, the transfer is executed but flag clearing is not performed for the selected internal interrupt even if the DTA bit is set to 1.

An internal interrupt request following the end of transfer or a forcible termination should be handled by the CPU as necessary.

7.7.8 Channel Re-Setting

To reactivate a number of channels when multiple channels are enabled, use exclusive handling of transfer end interrupts, and perform DMABCR control bit operations exclusively.

Note, in particular, that in cases where multiple interrupts are generated between reading and writing of DMABCR, and a DMABCR operation is performed during new interrupt handling, the DMABCR write data in the original interrupt handling routine will be incorrect, and the write may invalidate the results of the operations by the multiple interrupts. Ensure that overlapping DMABCR operations are not performed by multiple interrupts, and that there is no separation between read and write operations by the use of a bit-manipulation instruction.

Also, when the DTE and DTME bits are cleared by the DMAC or are written with 0, they must first be read while cleared to 0 before the CPU can write 1 to them.

Section 8 Data Transfer Controller (DTC)

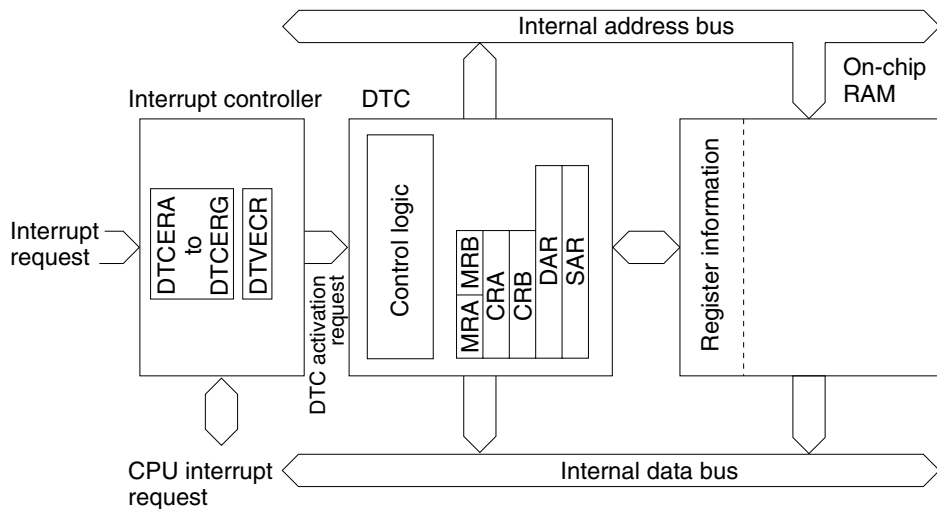

This LSI includes a data transfer controller (DTC). The DTC can be activated by an interrupt or software, to transfer data.

Figure 8.1 shows a block diagram of the DTC.

8.1 Features

- Transfer possible over any number of channels
- Three transfer modes
 - Normal mode
 - One operation transfers one byte or one word of data.
 - Memory address is incremented or decremented by 1 or 2.
 - From 1 to 65,536 transfers can be specified.
 - Repeat mode
 - One operation transfers one byte or one word of data.
 - Memory address is incremented or decremented by 1 or 2.
 - Once the specified number of transfers (1 to 256) has ended, the initial state is restored, and transfer is repeated.
 - Block transfer mode
 - One operation transfers one block of data.
 - The block size is 1 to 256 bytes or words.
 - From 1 to 65,536 transfers can be specified.
 - Either the transfer source or the transfer destination is designated as a block area.
- One activation source can trigger a number of data transfers (chain transfer)
- Direct specification of 16-Mbyte address space possible
- Activation by software is possible
- Transfer can be set in byte or word units
- A CPU interrupt can be requested for the interrupt that activated the DTC
- Module stop mode can be set

The DTC's register information is stored in the on-chip RAM. When the DTC is used, the RAME bit in SYSCR must be set to 1. A 32-bit bus connects the DTC to the on-chip RAM (1 kbyte), enabling 32-bit/1-state reading and writing of the DTC register information.

Legend

MRA, MRB	: DTC mode registers A and B
CRA, CRB	: DTC transfer count registers A and B
SAR	: DTC source address register
DAR	: DTC destination address register
DTCERA to DTCERG	: DTC enable registers A to G
DTVECR	: DTC vector register

Figure 8.1 Block Diagram of DTC

8.2 Register Descriptions

DTC has the following registers.

- DTC mode register A (MRA)
- DTC mode register B (MRB)
- DTC source address register (SAR)
- DTC destination address register (DAR)
- DTC transfer count register A (CRA)
- DTC transfer count register B (CRB)

These six registers cannot be directly accessed from the CPU. When activated, the DTC reads a set of register information that is stored in an on-chip RAM to the corresponding DTC registers and transfers data. After the data transfer, it writes a set of updated register information back to the RAM.

- DTC enable registers A to G (DTCERA to DTCERG)
- DTC vector register (DTVECR)

8.2.1 DTC Mode Register A (MRA)

MRA selects the DTC operating mode.

Bit	Bit Name	Initial Value	R/W	Description
7	SM1	Undefined	—	Source Address Mode 1 and 0
6	SM0	Undefined	—	These bits specify an SAR operation after a data transfer. 0x: SAR is fixed 10: SAR is incremented after a transfer (by +1 when Sz = 0; by +2 when Sz = 1) 11: SAR is decremented after a transfer (by -1 when Sz = 0; by -2 when Sz = 1)
5	DM1	Undefined	—	Destination Address Mode 1 and 0
4	DM0	Undefined	—	These bits specify a DAR operation after a data transfer. 0x: DAR is fixed 10: DAR is incremented after a transfer (by +1 when Sz = 0; by +2 when Sz = 1) 11: DAR is decremented after a transfer (by -1 when Sz = 0; by -2 when Sz = 1)
3	MD1	Undefined	—	DTC Mode
2	MD0	Undefined	—	These bits specify the DTC transfer mode. 00: Normal mode 01: Repeat mode 10: Block transfer mode 11: Setting prohibited
1	DTS	Undefined	—	DTC Transfer Mode Select Specifies whether the source side or the destination side is set to be a repeat area or block area, in repeat mode or block transfer mode. 0: Destination side is repeat area or block area 1: Source side is repeat area or block area
0	Sz	Undefined	—	DTC Data Transfer Size Specifies the size of data to be transferred. 0: Byte-size transfer 1: Word-size transfer

Legend:

X : Don't care

8.2.2 DTC Mode Register B (MRB)

MRB selects the DTC operating mode.

Bit	Bit Name	Initial Value	R/W	Description
7	CHNE	Undefined	—	DTC Chain Transfer Enable When this bit is set to 1, a chain transfer will be performed. For details, refer to section 8.5.4, Chain Transfer. In data transfer with CHNE set to 1, determination of the end of the specified number of transfers, clearing of the activation source flag, and clearing of DTCER is not performed.
6	DISEL	Undefined	—	DTC Interrupt Select When this bit is set to 1, a CPU interrupt request is generated every time after a data transfer ends. When this bit is set to 0, a CPU interrupt request is generated at the time when the specified number of data transfer ends.
5	CHNS	Undefined	—	DTC Chain Transfer Select Specifies the chain transfer condition. 0: Chain transfer every time 1: Chain transfer only when transfer counter = 0
4 to 0	—	Undefined	—	Reserved These bits have no effect on DTC operation, and should always be written with 0.

8.2.3 DTC Source Address Register (SAR)

SAR is a 24-bit register that designates the source address of data to be transferred by the DTC. For word-size transfer, specify an even source address.

8.2.4 DTC Destination Address Register (DAR)

DAR is a 24-bit register that designates the destination address of data to be transferred by the DTC. For word-size transfer, specify an even destination address.

8.2.5 DTC Transfer Count Register A (CRA)

CRA is a 16-bit register that designates the number of times data is to be transferred by the DTC.

In normal mode, the entire CRA functions as a 16-bit transfer counter (1 to 65,536). It is decremented by 1 every time data is transferred, and transfer ends when the count reaches H'0000.

In repeat mode or block transfer mode, the CRA is divided into two parts: the upper 8 bits (CRAH) and the lower 8 bits (CRAL). CRAH holds the number of transfers while CRAL functions as an 8-bit transfer counter (1 to 256). CRAL is decremented by 1 every time data is transferred, and the contents of CRAH are sent when the count reaches H'00.

8.2.6 DTC Transfer Count Register B (CRB)

CRB is a 16-bit register that designates the number of times data is to be transferred by the DTC in block transfer mode. It functions as a 16-bit transfer counter (1 to 65,536) that is decremented by 1 every time data is transferred, and transfer ends when the count reaches H'0000.

This register is not used in normal mode or repeat mode.

8.2.7 DTC Enable Registers A to G (DTCERA to DTCERG)

DTCER which is comprised of seven registers, DTCERA to DTCERG, is a register that specifies DTC activation interrupt sources. The correspondence between interrupt sources and DTCE bits is shown in table 8.1. For DTCE bit setting, use bit manipulation instructions such as BSET and BCLR for reading and writing. If all interrupts are masked, multiple activation sources can be set at one time (only at the initial setting) by writing data after executing a dummy read on the relevant register.

Bit	Bit Name	Initial Value	R/W	Description
7	DTCE7	0	R/W	DTC Activation Enable
6	DTCE6	0	R/W	Setting this bit to 1 specifies a relevant interrupt source to a DTC activation source.
5	DTCE5	0	R/W	
4	DTCE4	0	R/W	[Clearing conditions]
3	DTCE3	0	R/W	
2	DTCE2	0	R/W	<ul style="list-style-type: none"> When the DISEL bit is 1 and the data transfer has ended When the specified number of transfers have ended
1	DTCE1	0	R/W	
0	DTCE0	0	R/W	
				These bits are not cleared when the DISEL bit is 0 and the specified number of transfers have not ended

8.2.8 DTC Vector Register (DTVECR)

DTVECR enables or disables DTC activation by software, and sets a vector number for the software activation interrupt.

Bit	Bit Name	Initial Value	R/W	Description
7	SWDTE	0	R/W	<p>DTC Software Activation Enable</p> <p>Setting this bit to 1 activates DTC. Only 1 can be written to this bit.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • When the DISEL bit is 0 and the specified number of transfers have not ended • When 0 is written to the DISEL bit after a software-activated data transfer end interrupt (SWDTEND) request has been sent to the CPU. <p>When the DISEL bit is 1 and data transfer has ended or when the specified number of transfers have ended, this bit will not be cleared.</p>
6	DTVEC6	0	R/W	DTC Software Activation Vectors 6 to 0
5	DTVEC5	0	R/W	These bits specify a vector number for DTC software activation.
4	DTVEC4	0	R/W	
3	DTVEC3	0	R/W	The vector address is expressed as H'0400 + (vector number × 2). For example, when DTVEC6 to
2	DTVEC2	0	R/W	
1	DTVEC1	0	R/W	DTVEC0 = H'10, the vector address is H'0420. When the bit SWDTE is 0, these bits can be written.
0	DTVEC0	0	R/W	

8.3 Activation Sources

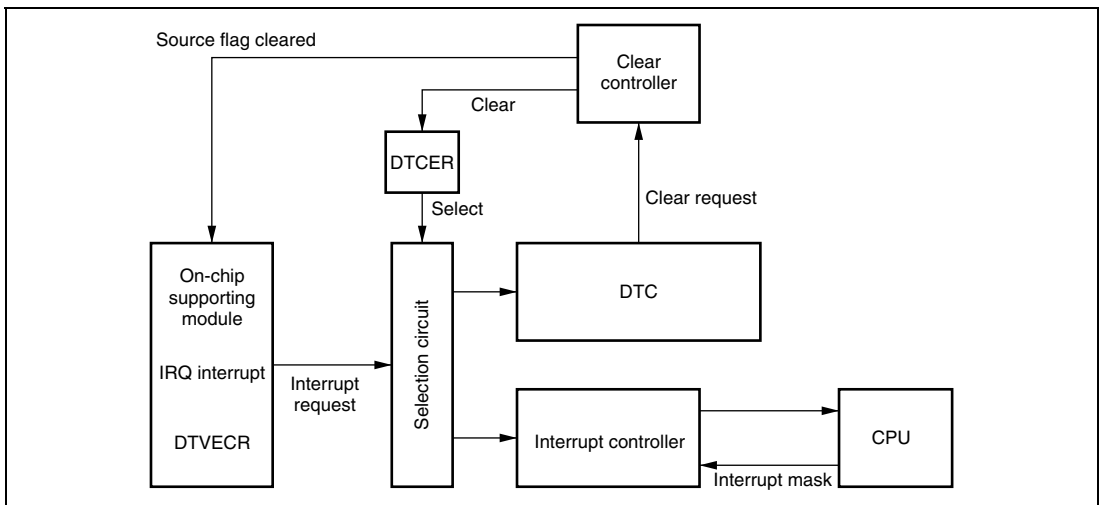

The DTC operates when activated by an interrupt or by a write to DTVECR by software. An interrupt request can be directed to the CPU or DTC, as designated by the corresponding DTCER bit. At the end of a data transfer (or the last consecutive transfer in the case of chain transfer), the activation source or corresponding DTCER bit is cleared. The activation source flag, in the case of RXI0, for example, is the RDRF flag of SCI_0.

When an interrupt has been designated a DTC activation source, existing CPU mask level and interrupt controller priorities have no effect. If there is more than one activation source at the same time, the DTC operates in accordance with the default priorities.

Table 8.1 shows the relationship between the activation sources and DTCER clearing, and figure 8.2 shows a block diagram of activation source control. For details see section 5, Interrupt Controller.

Table 8.1 Relationship between Activation Sources and DTCER Clearing

Activation Source	DISEL = 0 and Specified Number of Transfers Has Not Ended	DISEL = 1 or Specified Number of Transfers Has Ended
Activation by software	SWDTE bit is cleared to 0	<ul style="list-style-type: none">• SWDTE bit remains set to 1• Interrupt request to CPU
Activation by an interrupt	<ul style="list-style-type: none">• Corresponding DTCER bit remains set to 1.• Activation source flag is cleared to 0.	<ul style="list-style-type: none">• Corresponding DTCER bit is cleared to 0.• Activation source flag remains set to 1.• Interrupt that became the activation source is requested to the CPU.

**Figure 8.2 Block Diagram of DTC Activation Source Control**

8.4 Location of Register Information and DTC Vector Table

Locate the register information in the on-chip RAM (addresses: H'FFBC00 to H'FFBFFF). Register information should be located at the address that is multiple of four within the range. Locating the register information in address space is shown in figure 8.3. Locate the MRA, SAR, MRB, DAR, CRA, and CRB registers, in that order, from the start address of the register information. In the case of chain transfer, register information should be located in consecutive areas as shown in figure 8.3 and the register information start address should be located at the corresponding vector address to the activation source. Figure 8.4 shows the correspondence between the DTC vector address and register information. The DTC reads the start address of the

register information from the vector address set for each activation source, and then reads the register information from that start address.

When the DTC is activated by software, the vector address is obtained from: $H'0400 + (DTVECR[6:0] \times 2)$. For example, if DTVECR is H'10, the vector address is H'0420.

The configuration of the vector address is the same in both normal* and advanced modes, a 2-byte unit being used in both cases. These two bytes specify the lower bits of the register information start address.

Note: * Not available in this LSI.

Notes: *1 DTCE bits with no corresponding interrupt are reserved, and should be written with 0.
When clearing the software standby state or all-module-clocks-stop mode with an interrupt, write 0 to the corresponding DTCE bit.

*2 The DMAC is not supported by the H8S/2366.

8.5 Operation

The DTC stores register information in the on-chip RAM. When activated, the DTC reads register information that is already stored in the on-chip RAM and transfers data on the basis of that register information. After the data transfer, it writes updated register information back to the on-chip RAM. Pre-storage of register information in the on-chip RAM makes it possible to transfer data over any required number of channels. There are three transfer modes: normal mode, repeat mode, and block transfer mode. Setting the CHNE bit to 1 makes it possible to perform a number of transfers with a single activation (chain transfer). A setting can also be made to have chain transfer performed only when the transfer counter value is 0. This enables DTC re-setting to be performed by the DTC itself.

The 24-bit SAR designates the DTC transfer source address and the 24-bit DAR designates the transfer destination address. After each transfer, SAR and DAR are independently incremented, decremented, or left fixed.

Figure 8.5 shows a flowchart of DTC operation, and table 8.3 summarizes the chain transfer conditions (combinations for performing the second and third transfers are omitted).

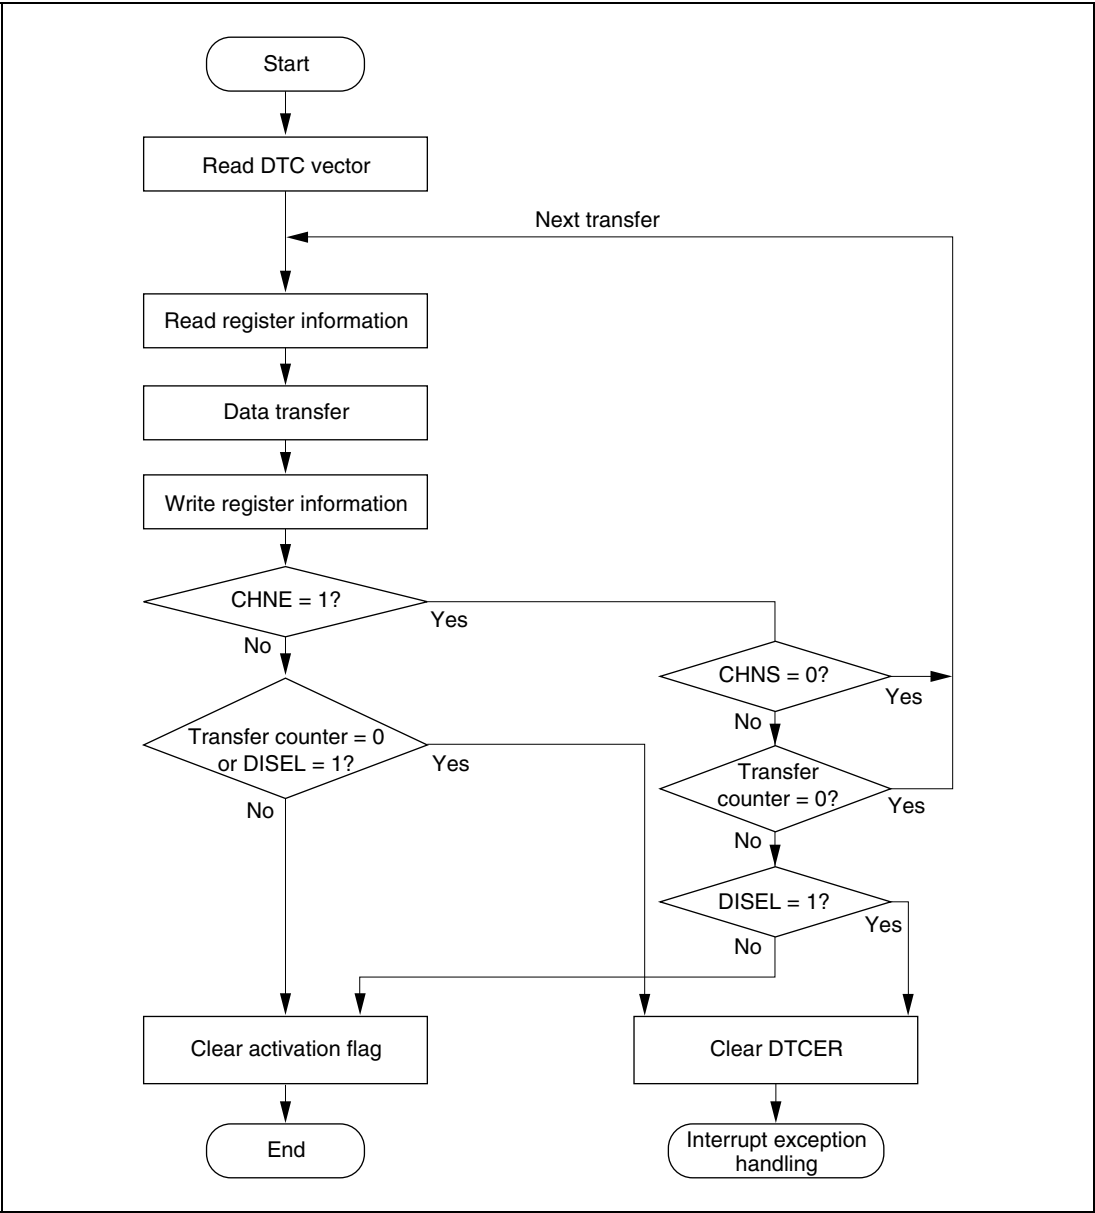

Figure 8.5 Flowchart of DTC Operation

Table 8.3 Chain Transfer Conditions

1st Transfer				2nd Transfer				DTC Transfer
CHNE	CHNS	DISEL	CR	CHNE	CHNS	DISEL	CR	
0	—	0	Not 0	—	—	—	—	Ends at 1st transfer
0	—	0	0	—	—	—	—	Ends at 1st transfer
0	—	1	—	—	—	—	—	Interrupt request to CPU
1	0	—	—	0	—	0	Not 0	Ends at 2nd transfer
				0	—	0	0	Ends at 2nd transfer

				0	—	1	—	Interrupt request to CPU
1	1	1	Not 0	—	—	—	—	Ends at 1st transfer
								Interrupt request to CPU

8.5.1 Normal Mode

In normal mode, one operation transfers one byte or one word of data. Table 8.4 lists the register function in normal mode. From 1 to 65,536 transfers can be specified. Once the specified number of transfers has ended, a CPU interrupt can be requested.

Table 8.4 Register Function in Normal Mode

Name	Abbreviation	Function
DTC source address register	SAR	Designates source address
DTC destination address register	DAR	Designates destination address
DTC transfer count register A	CRA	Designates transfer count
DTC transfer count register B	CRB	Not used

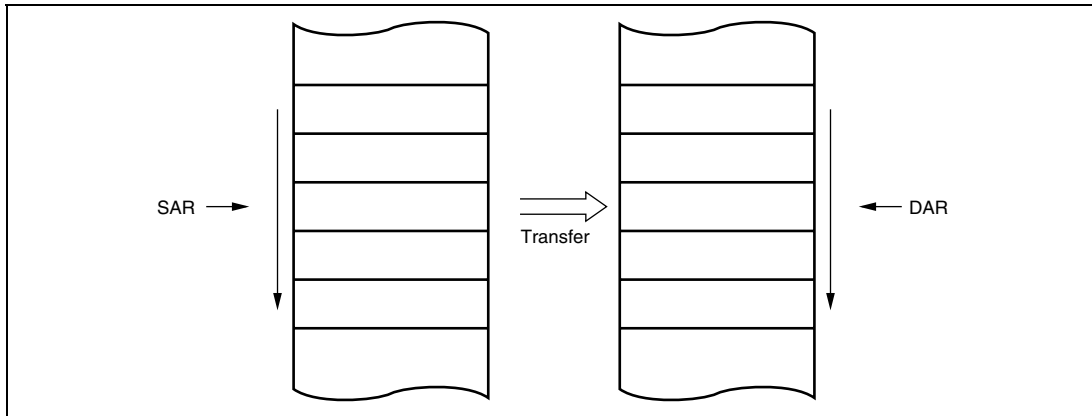

Figure 8.6 Memory Mapping in Normal Mode

8.5.2 Repeat Mode

In repeat mode, one operation transfers one byte or one word of data. Table 8.5 lists the register function in repeat mode. From 1 to 256 transfers can be specified. Once the specified number of transfers has ended, the initial state of the transfer counter and the address register specified as the repeat area is restored, and transfer is repeated. In repeat mode the transfer counter value does not reach H'00, and therefore CPU interrupts cannot be requested when DISEL = 0.

Table 8.5 Register Function in Repeat Mode

Name	Abbreviation	Function
DTC source address register	SAR	Designates source address
DTC destination address register	DAR	Designates destination address
DTC transfer count register AH	CRAH	Holds number of transfers
DTC transfer count register AL	CRAL	Designates transfer count
DTC transfer count register B	CRB	Not used

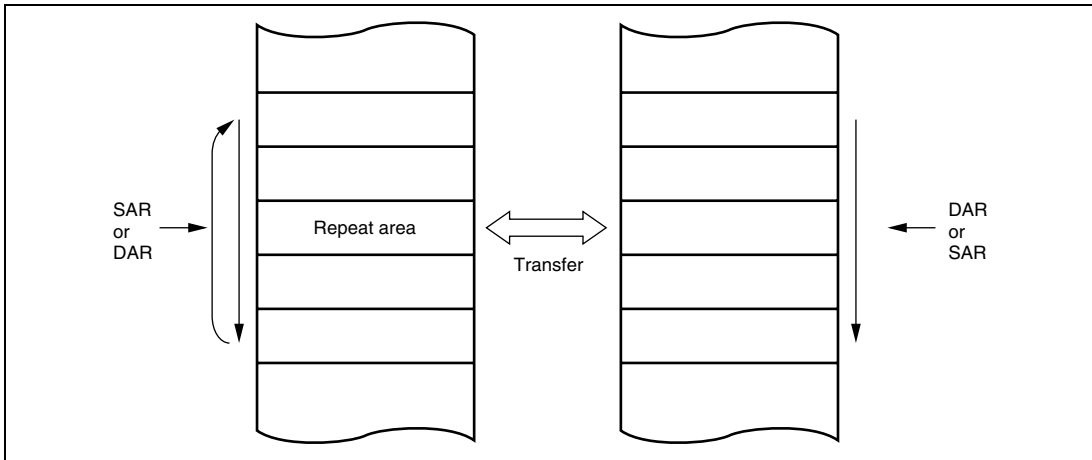

Figure 8.7 Memory Mapping in Repeat Mode

8.5.3 Block Transfer Mode

In block transfer mode, one operation transfers one block of data. Either the transfer source or the transfer destination is designated as a block area. Table 8.6 lists the register function in block transfer mode.

The block size is 1 to 256. When the transfer of one block ends, the initial state of the block size counter and the address register specified as the block area is restored. The other address register is then incremented, decremented, or left fixed. From 1 to 65,536 transfers can be specified. Once the specified number of transfers has ended, a CPU interrupt is requested.

Table 8.6 Register Function in Block Transfer Mode

Name	Abbreviation	Function
DTC source address register	SAR	Designates source address
DTC destination address register	DAR	Designates destination address
DTC transfer count register AH	CRAH	Holds block size
DTC transfer count register AL	CRAL	Designates block size count
DTC transfer count register B	CRB	Designates transfer count

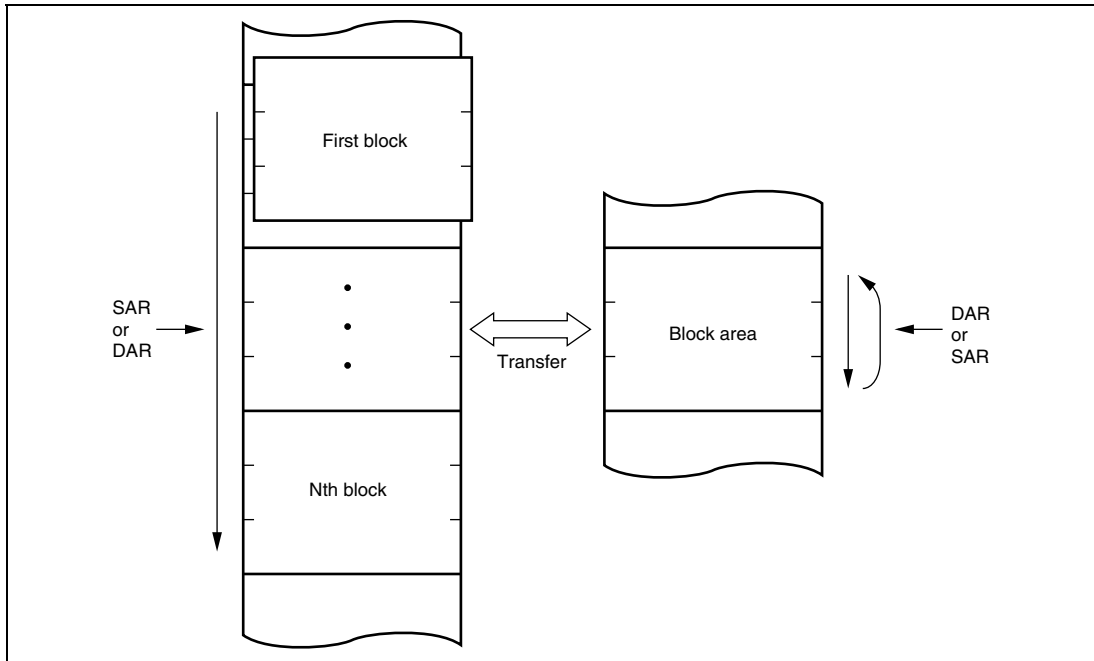

Figure 8.8 Memory Mapping in Block Transfer Mode

8.5.4 Chain Transfer

Setting the CHNE bit to 1 enables a number of data transfers to be performed consecutively in response to a single transfer request. SAR, DAR, CRA, CRB, MRA, and MRB, which define data transfers, can be set independently.

Figure 8.9 shows the operation of chain transfer. When activated, the DTC reads the register information start address stored at the vector address, and then reads the first register information at that start address. The CHNE bit in MRB is checked after the end of data transfer, if the value is 1, the next register information, which is located consecutively, is read and transfer is performed. This operation is repeated until the end of data transfer of register information with CHNE = 0. It is also possible, by setting both the CHNE bit and CHNS bit to 1, to specify execution of chain transfer only when the transfer counter value is 0.

In the case of transfer with CHNE set to 1, an interrupt request to the CPU is not generated at the end of the specified number of transfers or by setting of the DISEL bit to 1, and the interrupt source flag for the activation source is not affected.

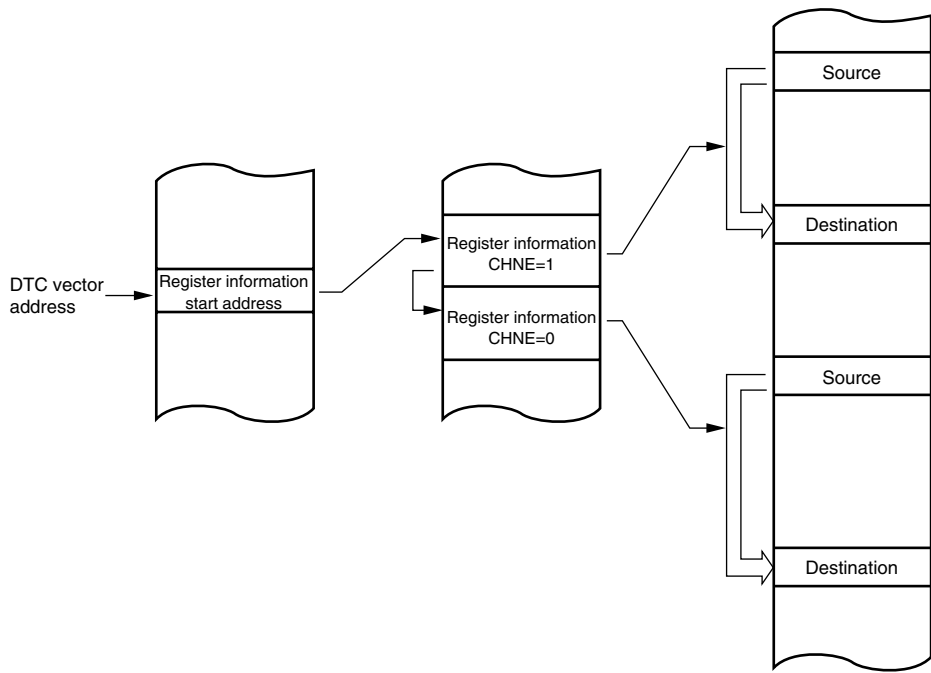

Figure 8.9 Operation of Chain Transfer

8.5.5 Interrupts

An interrupt request is issued to the CPU when the DTC finishes the specified number of data transfers, or a data transfer for which the DISEL bit was set to 1. In the case of interrupt activation, the interrupt set as the activation source is generated. These interrupts to the CPU are subject to CPU mask level and interrupt controller priority level control.

In the case of activation by software, a software activated data transfer end interrupt (SWDTEND) is generated.

When the DISEL bit is 1 and one data transfer has ended, or the specified number of transfers has ended, after data transfer ends, the SWDTE bit is held at 1 and an SWDTEND interrupt is generated. The interrupt handling routine should clear the SWDTE bit to 0.

When the DTC is activated by software, an SWDTEND interrupt is not generated during a data transfer wait or during data transfer even if the SWDTE bit is set to 1.

8.5.6 Operation Timing

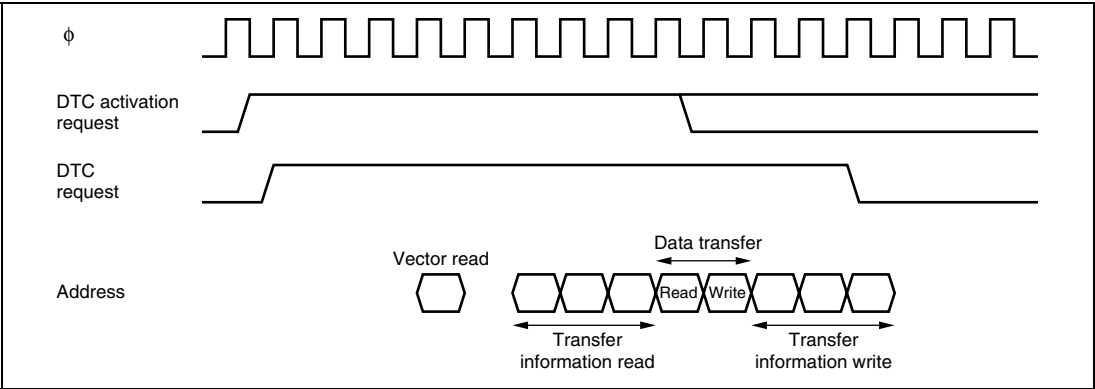

Figure 8.10 DTC Operation Timing (Example in Normal Mode or Repeat Mode)

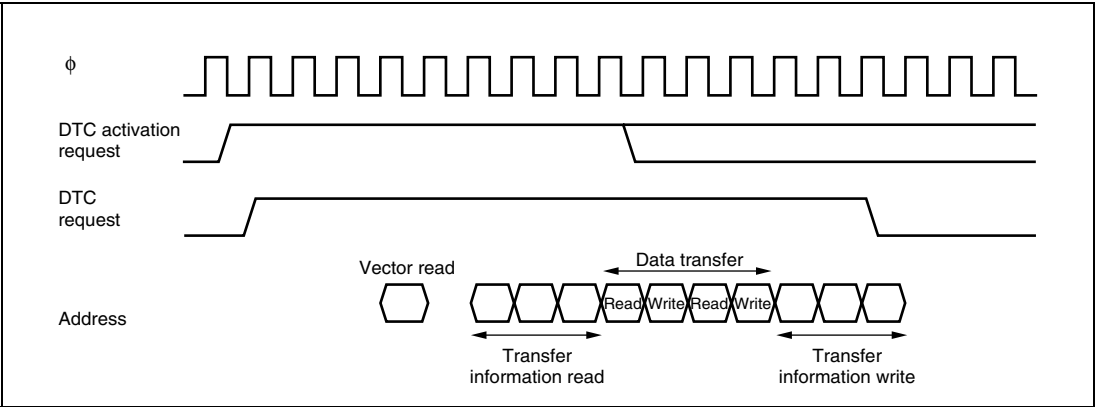

Figure 8.11 DTC Operation Timing (Example of Block Transfer Mode, with Block Size of 2)

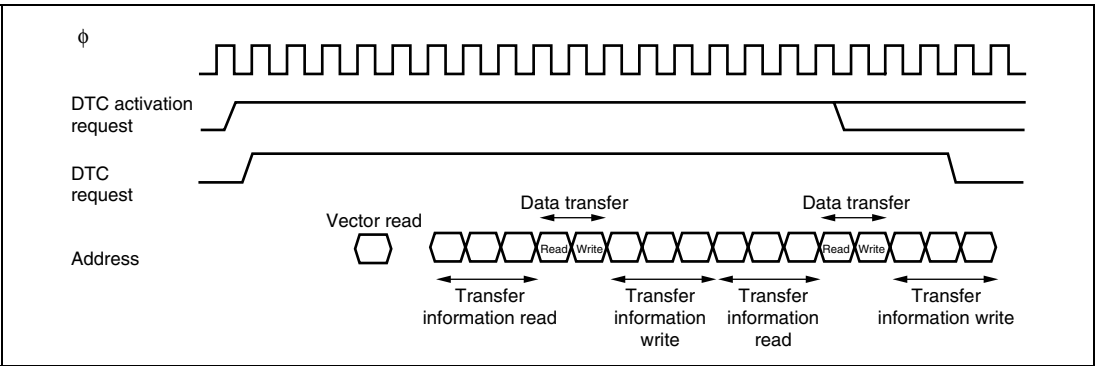

Figure 8.12 DTC Operation Timing (Example of Chain Transfer)

8.5.7 Number of DTC Execution States

Table 8.7 lists execution status for a single DTC data transfer, and table 8.7 shows the number of states required for each execution status.

Table 8.7 DTC Execution Status

Mode	Vector Read I	Register Information Read/Write J	Data Read K	Data Write L	Internal Operations M
Normal	1	6	1	1	3
Repeat	1	6	1	1	3
Block transfer	1	6	N	N	3

Legend:

N: Block size (initial setting of CRAH and CRAL)

Table 8.8 Number of States Required for Each Execution Status

Object to be Accessed		On-Chip RAM	On-Chip ROM	On-Chip I/O Registers		External Devices			
Bus width		32	16	8	16	8	16		
Access states		1	1	2	2	2	3	2	3
Execution status	Vector read S_I	—	1	—	—	4	6+2m	2	3+m
	Register information read/write S_J	1	—	—	—	—	—	—	—
	Byte data read S_K	1	1	2	2	2	3+m	2	3+m
	Word data read S_K	1	1	4	2	4	6+2m	2	3+m
	Byte data write S_L	1	1	2	2	2	3+m	2	3+m
	Word data write S_L	1	1	4	2	4	6+2m	2	3+m
Internal operation S_M		1							

The number of execution states is calculated from the formula below. Note that Σ means the sum of all transfers activated by one activation event (the number in which the CHNE bit is set to 1, plus 1).

$$\text{Number of execution states} = I \cdot S_I + \Sigma (J \cdot S_J + K \cdot S_K + L \cdot S_L) + M \cdot S_M$$

For example, when the DTC vector address table is located in on-chip ROM, normal mode is set, and data is transferred from the on-chip ROM to an internal I/O register, the time required for the DTC operation is 13 states. The time from activation to the end of the data write is 10 states.

8.6 Procedures for Using DTC

8.6.1 Activation by Interrupt

The procedure for using the DTC with interrupt activation is as follows:

1. Set the MRA, MRB, SAR, DAR, CRA, and CRB register information in the on-chip RAM.
2. Set the start address of the register information in the DTC vector address.
3. Set the corresponding bit in DTCER to 1.
4. Set the enable bits for the interrupt sources to be used as the activation sources to 1. The DTC is activated when an interrupt used as an activation source is generated.
5. After the end of one data transfer, or after the specified number of data transfers have ended, the DTCE bit is cleared to 0 and a CPU interrupt is requested. If the DTC is to continue transferring data, set the DTCE bit to 1.

8.6.2 Activation by Software

The procedure for using the DTC with software activation is as follows:

1. Set the MRA, MRB, SAR, DAR, CRA, and CRB register information in the on-chip RAM.
2. Set the start address of the register information in the DTC vector address.
3. Check that the SWDTE bit is 0.
4. Write 1 to SWDTE bit and the vector number to DTVECR.
5. Check the vector number written to DTVECR.
6. After the end of one data transfer, if the DISEL bit is 0 and a CPU interrupt is not requested, the SWDTE bit is cleared to 0. If the DTC is to continue transferring data, set the SWDTE bit to 1. When the DISEL bit is 1, or after the specified number of data transfers have ended, the SWDTE bit is held at 1 and a CPU interrupt is requested.

8.7 Examples of Use of the DTC

8.7.1 Normal Mode

An example is shown in which the DTC is used to receive 128 bytes of data via the SCI.

1. Set MRA to fixed source address ($SM1 = SM0 = 0$), incrementing destination address ($DM1 = 1$, $DM0 = 0$), normal mode ($MD1 = MD0 = 0$), and byte size ($Sz = 0$). The DTS bit can have any value. Set MRB for one data transfer by one interrupt ($CHNE = 0$, $DISEL = 0$). Set the SCI RDR address in SAR, the start address of the RAM area where the data will be received in DAR, and 128 (H'0080) in CRA. CRB can be set to any value.
2. Set the start address of the register information at the DTC vector address.

3. Set the corresponding bit in DTCER to 1.
4. Set the SCI to the appropriate receive mode. Set the RIE bit in SCR to 1 to enable the reception complete (RXI) interrupt. Since the generation of a receive error during the SCI reception operation will disable subsequent reception, the CPU should be enabled to accept receive error interrupts.
5. Each time reception of one byte of data ends on the SCI, the RDRF flag in SSR is set to 1, an RXI interrupt is generated, and the DTC is activated. The receive data is transferred from RDR to RAM by the DTC. DAR is incremented and CRA is decremented. The RDRF flag is automatically cleared to 0.
6. When CRA becomes 0 after the 128 data transfers have ended, the RDRF flag is held at 1, the DTCE bit is cleared to 0, and an RXI interrupt request is sent to the CPU. The interrupt handling routine should perform wrap-up processing.

8.7.2 Chain Transfer

An example of DTC chain transfer is shown in which pulse output is performed using the PPG*. Chain transfer can be used to perform pulse output data transfer and PPG output trigger cycle updating. Repeat mode transfer to the PPG's NDR is performed in the first half of the chain transfer, and normal mode transfer to the TPU's TGR in the second half. This is because clearing of the activation source and interrupt generation at the end of the specified number of transfers are restricted to the second half of the chain transfer (transfer when CHNE = 0).

1. Perform settings for transfer to the PPG's NDR. Set MRA to source address incrementing (SM1 = 1, SM0 = 0), fixed destination address (DM1 = DM0 = 0), repeat mode (MD1 = 0, MD0 = 1), and word size (Sz = 1). Set the source side as a repeat area (DTS = 1). Set MRB to chain mode (CHNE = 1, DISEL = 0). Set the data table start address in SAR, the NDRH address in DAR, and the data table size in CRAH and CRAL. CRB can be set to any value.
2. Perform settings for transfer to the TPU's TGR. Set MRA to source address incrementing (SM1 = 1, SM0 = 0), fixed destination address (DM1 = DM0 = 0), normal mode (MD1 = MD0 = 0), and word size (Sz = 1). Set the data table start address in SAR, the TGRA address in DAR, and the data table size in CRA. CRB can be set to any value.
3. Locate the TPU transfer register information consecutively after the NDR transfer register information.
4. Set the start address of the NDR transfer register information to the DTC vector address.
5. Set the bit corresponding to TGIA in DTCER to 1.
6. Set TGRA as an output compare register (output disabled) with TIOR, and enable the TGIA interrupt with TIER.
7. Set the initial output value in PODR, and the next output value in NDR. Set bits in DDR and NDER for which output is to be performed to 1. Using PCR, select the TPU compare match to be used as the output trigger.
8. Set the CST bit in TSTR to 1, and start the TCNT count operation.

9. Each time a TGRA compare match occurs, the next output value is transferred to NDR and the set value of the next output trigger period is transferred to TGRA. The activation source TGFA flag is cleared.
10. When the specified number of transfers are completed (the TPU transfer CRA value is 0), the TGFA flag is held at 1, the DTCE bit is cleared to 0, and a TGIA interrupt request is sent to the CPU. Termination processing should be performed in the interrupt handling routine.

Note: * The PPG is not supported by the H8S/2366.

8.7.3 Chain Transfer when Counter = 0

By executing a second data transfer, and performing re-setting of the first data transfer, only when the counter value is 0, it is possible to perform 256 or more repeat transfers.

An example is shown in which a 128-kbyte input buffer is configured. The input buffer is assumed to have been set to start at lower address H'0000. Figure 8.13 shows the chain transfer when the counter value is 0.

1. For the first transfer, set the normal mode for input data. Set fixed transfer source address (G/A, etc.), CRA = H'0000 (65,536 times), and CHNE = 1, CHNS = 1, and DISEL = 0.
2. Prepare the upper 8-bit addresses of the start addresses for each of the 65,536 transfer start addresses for the first data transfer in a separate area (in ROM, etc.). For example, if the input buffer comprises H'200000 to H'21FFFF, prepare H'21 and H'20.
3. For the second transfer, set repeat mode (with the source side as the repeat area) for re-setting the transfer destination address for the first data transfer. Use the upper 8 bits of DAR in the first register information area as the transfer destination. Set CHNE = DISEL = 0. If the above input buffer is specified as H'200000 to H'21FFFF, set the transfer counter to 2.
4. Execute the first data transfer 65,536 times by means of interrupts. When the transfer counter for the first data transfer reaches 0, the second data transfer is started. Set the upper 8 bits of the transfer source address for the first data transfer to H'21. The lower 16 bits of the transfer destination address of the first data transfer and the transfer counter are H'0000.
5. Next, execute the first data transfer the 65,536 times specified for the first data transfer by means of interrupts. When the transfer counter for the first data transfer reaches 0, the second data transfer is started. Set the upper 8 bits of the transfer source address for the first data transfer to H'20. The lower 16 bits of the transfer destination address of the first data transfer and the transfer counter are H'0000.
6. Steps 4 and 5 are repeated endlessly. As repeat mode is specified for the second data transfer, an interrupt request is not sent to the CPU.

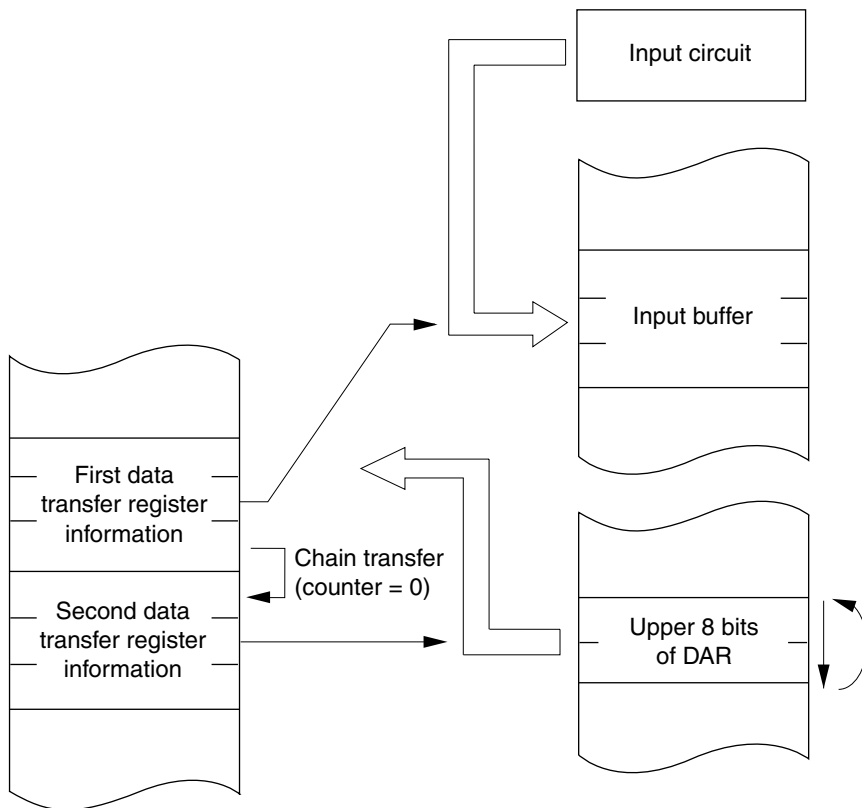

Figure 8.13 Chain Transfer when Counter = 0

8.7.4 Software Activation

An example is shown in which the DTC is used to transfer a block of 128 bytes of data by means of software activation. The transfer source address is H'1000 and the destination address is H'2000. The vector number is H'60, so the vector address is H'04C0.

1. Set MRA to incrementing source address (SM1 = 1, SM0 = 0), incrementing destination address (DM1 = 1, DM0 = 0), block transfer mode (MD1 = 1, MD0 = 0), and byte size (Sz = 0). The DTS bit can have any value. Set MRB for one block transfer by one interrupt (CHNE = 0). Set the transfer source address (H'1000) in SAR, the destination address (H'2000) in DAR, and 128 (H'8080) in CRA. Set 1 (H'0001) in CRB.
2. Set the start address of the register information at the DTC vector address (H'04C0).
3. Check that the SWDTE bit in DTVECR is 0. Check that there is currently no transfer activated by software.
4. Write 1 to the SWDTE bit and the vector number (H'60) to DTVECR. The write data is H'E0.

5. Read DTVECR again and check that it is set to the vector number (H'60). If it is not, this indicates that the write failed. This is presumably because an interrupt occurred between steps 3 and 4 and led to a different software activation. To activate this transfer, go back to step 3.
6. If the write was successful, the DTC is activated and a block of 128 bytes of data is transferred.
7. After the transfer, an SWDTEND interrupt occurs. The interrupt handling routine should clear the SWDTE bit to 0 and perform other wrap-up processing.

8.8 Usage Notes

8.8.1 Module Stop Mode Setting

DTC operation can be disabled or enabled using the module stop control register. The initial setting is for DTC operation to be enabled. Register access is disabled by setting module stop mode. Module stop mode cannot be set while the DTC is activated. For details, refer to section 22, Power-Down Modes.

8.8.2 On-Chip RAM

The MRA, MRB, SAR, DAR, CRA, and CRB registers are all located in on-chip RAM. When the DTC is used, the RAME bit in SYSCR must not be cleared to 0.

8.8.3 DTCE Bit Setting

For DTCE bit setting, use bit manipulation instructions such as BSET and BCLR. If all interrupts are disabled, multiple activation sources can be set at one time (only at the initial setting) by writing data after executing a dummy read on the relevant register.

8.8.4 DMAC Transfer End Interrupt

When DTC transfer is activated by a DMAC transfer end interrupt, regardless of the transfer counter and DIESEL bit, the DMAC's DTE bit is not subject to DTC control, and the write data has priority. Consequently, an interrupt request may not be sent to the CPU when the DTC transfer counter reaches 0.

Note: Not supported by the H8S/2366.

8.8.5 Chain Transfer

When chain transfer is used, clearing of the activation source or DTCER is performed when the last of the chain of data transfers is executed. SCI and high-speed A/D converter interrupt/activation sources, on the other hand, are cleared when the DTC reads or writes to the prescribed register.

Therefore, when the DTC is activated by an interrupt or activation source, if a read/write of the relevant register is not included in the last chained data transfer, the interrupt or activation source will be retained.

Section 9 I/O Ports

Table 9.1 summarizes the port functions. The pins of each port also have other functions such as input/output or external interrupt input pins of on-chip peripheral modules. Each I/O port includes a data direction register (DDR) that controls input/output, a data register (DR) that stores output data, and a port register (PORT) used to read the pin states. The input-only ports do not have a DR or DDR register.

Ports A to E have a built-in pull-up MOS function and a pull-up MOS control register (PCR) to control the on/off state of MOS input pull-up.

Ports 3 and A include an open-drain control register (ODR) that controls the on/off state of the output buffer PMOS.

Ports 1 to 3, 5 (P50 to P53), and 8 (P81, P83, P85) can drive a single TTL load and 30 pF capacitive load. Ports A to G can drive a single TTL load and 50 pF capacitive load.

All of the I/O ports can drive a Darlington transistor when outputting data.

Ports 1 and 2 are Schmitt-triggered inputs. Ports 4, 5, and A (PA4, PA5, PA6, PA7) are Schmitt-triggered inputs when used as IRQ inputs.

*2 Not supported by the H8S/2366.

9.1 Port 1

Port 1 is an 8-bit I/O port that also has other functions. The port 1 has the following registers.

- Port 1 data direction register (P1DDR)
- Port 1 data register (P1DR)
- Port 1 register (PORT1)

9.1.1 Port 1 Data Direction Register (P1DDR)

The individual bits of P1DDR specify input or output for the pins of port 1.

Bit	Bit Name	Initial Value	R/W	Description
7	P17DDR	0	W	When a pin function is specified to a general purpose I/O, setting this bit to 1 makes the corresponding port 1 pin an output pin, while clearing this bit to 0 makes the pin an input pin.
6	P16DDR	0	W	
5	P15DDR	0	W	
4	P14DDR	0	W	
3	P13DDR	0	W	
2	P12DDR	0	W	
1	P11DDR	0	W	
0	P10DDR	0	W	

9.1.2 Port 1 Data Register (P1DR)

P1DR stores output data for the port 1 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P17DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	P16DR	0	R/W	
5	P15DR	0	R/W	
4	P14DR	0	R/W	
3	P13DR	0	R/W	
2	P12DR	0	R/W	
1	P11DR	0	R/W	
0	P10DR	0	R/W	

9.1.3 Port 1 Register (PORT1)

PORT1 shows the pin states.

PORT1 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	P17	—*	R	If a port 1 read is performed while P1DDR bits are set to 1, the P1DR values are read. If a port 1 read is performed while P1DDR bits are cleared to 0, the pin states are read.
6	P16	—*	R	
5	P15	—*	R	
4	P14	—*	R	
3	P13	—*	R	
2	P12	—*	R	
1	P11	—*	R	
0	P10	—*	R	

Note: * Determined by the states of pins P17 to P10.

9.1.4 Pin Functions

Port 1 pins also function as the pins for PPG outputs, TPU I/Os*, and DMAC outputs*. The correspondence between the register specification and the pin functions is shown below.

Note: * Not supported by the H8S/2366.

- P17/PO15*¹/TIOCB2/TCLKD

The pin function is switched as shown below according to the combination of the TPU channel 2 settings (by bits MD3 to MD0 in TMDR_2, bits IOB3 to IOB0 in TIOR_2, and bits CCLR1 and CCLR0 in TCR_2), bits TPSC2 to TPSC0 in TCR_0 and TCR_5, bit NDER15*¹ in NDERH, and bit P17DDR.

TPU channel 2 settings	(1) in table below	(2) in table below		
P17DDR	—	0	1	1
NDER15* ¹	—	—	0	1
Pin function	TIOCB2 output	P17 input	P17 output	PO15 output* ¹
		TIOCB2 input* ²		
	TCLKD input* ³			

Notes: *1 Not supported by the H8S/2366.

*2 TIOCB2 input when MD3 to MD0 = B'0000 or B'01xx and IOB3 = 1.

*3 TCLKD input when the setting for either TCR_0 or TCR_5 is TPSC2 to TPSC0 = B'111.
TCLKD input when channels 2 and 4 are set to phase counting mode.

TPU channel 2 settings	(2)	(1)	(2)	(2)	(1)	(2)
MD3 to MD0	B'0000, B'01xx		B'0010	B'0011		
IOB3 to IOB0	B'0000 B'0100 B'1xxx	B'0001 to B'0011 B'0101 to B'0111	—	B'xx00	Other than B'xx00	
CCLR1, CCLR0	—	—	—	—	Other than B'10	B'10
Output function	—	Output compare output	—	—	PWM mode 2 output	—

x: Don't care

- P16/PO14*¹/TIOCA2

The pin function is switched as shown below according to the combination of the TPU channel 2 settings (by bits MD3 to MD0 in TMDR_2, bits IOA3 to IOA0 in TIOR_2, and bits CCLR1 and CCLR0 in TCR_2), bit NDER14*¹ in NDERH, and bit P16DDR.

TPU channel 2 settings	(1) in table below	(2) in table below		
P16DDR	—	0	1	1
NDER14* ¹	—	—	0	1
Pin function	TIOCA2 output	P16 input	P16 output	PO14 output* ¹
		TIOCA2 input* ²		

Notes: *1 Not supported by the H8S/2366.

*2 TIOCA2 input when MD3 to MD0 = B'0000 or B'01xx and IOA3 = 1.

TPU channel 1 settings	(2)	(1)	(2)	(2)	(1)	(2)

9.2 Port 2

Port 2 is an 8-bit I/O port that also has other functions. The port 2 has the following registers.

- Port 2 data direction register (P2DDR)
- Port 2 data register (P2DR)
- Port 2 register (PORT2)

9.2.1 Port 2 Data Direction Register (P2DDR)

The individual bits of P2DDR specify input or output for the pins of port 2.

P2DDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	P27DDR	0	W	When a pin function is specified to a general purpose I/O, setting this bit to 1 makes the corresponding port 1 pin an output pin, while clearing this bit to 0 makes the pin an input pin.
6	P26DDR	0	W	
5	P25DDR	0	W	
4	P24DDR	0	W	
3	P23DDR	0	W	
2	P22DDR	0	W	
1	P21DDR	0	W	
0	P20DDR	0	W	

9.2.2 Port 2 Data Register (P2DR)

P2DR stores output data for the port 2 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P27DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	P26DR	0	R/W	
5	P25DR	0	R/W	
4	P24DR	0	R/W	
3	P23DR	0	R/W	
2	P22DR	0	R/W	
1	P21DR	0	R/W	
0	P20DR	0	R/W	

9.2.3 Port 2 Register (PORT2)

PORT2 shows the pin states.

PORT2 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	P27	—*	R	If a port 2 read is performed while P2DDR bits are set to 1, the P2DR values are read. If a port 2 read is performed while P2DDR bits are cleared to 0, the pin states are read.
6	P26	—*	R	
5	P25	—*	R	
4	P24	—*	R	
3	P23	—*	R	
2	P22	—*	R	
1	P21	—*	R	
0	P20	—*	R	

Note: * Determined by the states of pins P27 to P20.

9.2.4 Pin Functions

Port 2 pins also function as PPG outputs*, TPU I/Os, and TMR I/Os. The correspondence between the register specification and the pin functions is shown below.

Note: * Not supported by the H8S/2366.

- P27/PO7*¹/TIOCB5

The pin function is switched as shown below according to the combination of the TPU channel 5 settings (by bits MD3 to MD0 in TMDR_5, bits IOB3 to IOB0 in TIOR_5, and bits CCLR1 and CCLR0 in TCR_5), bit NDER7*¹ in NDERL, and bit P27DDR.

TPU channel 5 settings	(1) in table below	(2) in table below

Output function	—	Output compare output	—	PWM* ⁴ mode 1 output	PWM mode 2 output	—

x: Don't care

Note: *4 TIOCB3 output disabled.

9.3 Port 3

Port 3 is a 6-bit I/O port that also has other functions. The port 3 has the following registers.

- Port 3 data direction register (P3DDR)
- Port 3 data register (P3DR)
- Port 3 register (PORT3)
- Port 3 open drain control register (P3ODR)
- Port function control register 2(PFCR2)

9.3.1 Port 3 Data Direction Register (P3DDR)

The individual bits of P3DDR specify input or output for the pins of port 3.

P3DDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	P35DDR	0	W	When a pin function is specified to a general purpose I/O, setting this bit to 1 makes the corresponding port 1 pin an output pin, while clearing this bit to 0 makes the pin an input pin.
4	P34DDR	0	W	
3	P33DDR	0	W	
2	P32DDR	0	W	
1	P31DDR	0	W	
0	P30DDR	0	W	

9.3.2 Port 3 Data Register (P3DR)

P3DR stores output data for the port 3 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	P35DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
4	P34DR	0	R/W	
3	P33DR	0	R/W	
2	P32DR	0	R/W	
1	P31DR	0	R/W	
0	P30DR	0	R/W	

9.3.3 Port 3 Register (PORT3)

PORT3 shows the pin states.

PORT3 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	P35	—*	R	If a port 3 read is performed while P3DDR bits are set to 1, the P3DR values are read. If a port 1 read is performed while P3DDR bits are cleared to 0, the pin states are read.
4	P34	—*	R	
3	P33	—*	R	
2	P32	—*	R	
1	P31	—*	R	
0	P30	—*	R	

Note: * Determined by the states of pins P35 to P30.

9.3.4 Port 3 Open Drain Control Register (P3ODR)

P3ODR controls the output status for each port 3 pin.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	P35ODR	0	R/W	Setting a P3ODR bit to 1 makes the corresponding port 3 pin an NMOS open-drain output pin, while clearing the bit to 0 makes the pin a CMOS output pin.
4	P34ODR	0	R/W	
3	P33ODR	0	R/W	
2	P32ODR	0	R/W	
1	P31ODR	0	R/W	
0	P30ODR	0	R/W	

9.3.5 Port Function Control Register 2 (PFCR2)

PFCR2 controls the I/O port.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	—	Reserved These bits are always read as 0 and cannot be modified.
3	ASOE	1	R/W	\overline{AS} Output Enable Selects to enable or disable the \overline{AS} output pin. 0: PF6 is designated as I/O port 1: PF6 is designated as \overline{AS} output pin
2	LWROE	1	R/W	\overline{LWR} Output Enable Selects to enable or disable the \overline{LWR} output pin. 0: PF3 is designated as I/O port 1: PF3 is designated as \overline{LWR} output pin
1	OES*	1	R/W	\overline{OE} Output Select Selects the \overline{OE} output pin port when the OEE bit is set to 1 in DRAMCR (enabling \overline{OE} output). 0: P35 is designated as \overline{OE} output pin 1: PH3 is designated as \overline{OE} output pin
0	—	0	—	Reserved This bit is always read as 0 and cannot be modified.

Note: * In the H8S/2366, this bit is reserved. This bit is always read as 1 and the write value should always be 1.

9.3.6 Pin Functions

Port 3 pins also function as the pins for SCI I/Os, I²C output, and a bus control signal output. The correspondence between the register specification and the pin functions is shown below.

- P35/SCK1/SCL0/($\overline{\text{OE}}$)*³

The pin function is switched as shown below according to the combination of the ICE bit in ICCRA of I²C_0, C/ $\overline{\text{A}}$ bit in SMR of SCL_1, bits CKE0 and CKE1 in SCR, bits OEE in DRAMCR, bit OES in PFCR2, and bit P35DDR.

Modes 1, 2, 4, 7 (EXPE = 1)

OEE* ³	0						1						
OES* ³	—						1					0	
ICE	—				1		0				1	—	
CKE1	0				1	—	0				1	—	—
C/ $\overline{\text{A}}$	0			1	—	—	0			1	—	—	—
CKE0	0		1	—	—	—	0		1	—	—	—	—
P35DDR	0	1	—	—	—	—	0	1	—	—	—	—	—
Pin function	P35 input	P35 output* ¹	SCK1 output* ¹	SCK1 output* ¹	SCK1 input	SCL0 I/O* ²	P35 input	P35 output* ¹	SCK1 output* ¹	SCK1 output* ¹	SCK1 input	SCL0 I/O* ²	$\overline{\text{OE}}$ output* ³

Mode 7 (EXPE = 0)

OEE* ³	—					
OES* ³	—					
ICE	0					1
CKE1	0				1	—
C/ $\overline{\text{A}}$	0			1	—	—
CKE0	0		1	—	—	—
P35DDR	0	1	—	—	—	—
Pin function	P35 input	P35 output* ¹	SCK1 output* ¹	SCK1 output* ¹	SCK1 input	SCL0 I/O* ²

Notes: *1 NMOS open-drain output when P35ODR = 1.

*2 NMOS open-drain output regardless of P35ODR

*3 Not supported by the H8S/2366.

- P34/SCK0/SCK4/SDA0

The pin function is switched as shown below according to the combination of bit ICE in ICCRA of I²C_0, bit C/A in SMR, bits CKE0 and CKE1 in SCR, and bit P34DDR.

ICE	0					1
CKE1	0			1	—	
C/A	0		1	—	—	
CKE0	0		1	—	—	—
P34DDR	0	1	—	—	—	—
Pin function	P34 input	P34 output* ¹	SCK0/SCK4 output* ^{1*3}	SCK0/SCK4 output* ^{1*3}	SCK0/SCK4 input	SDA0 I/O* ²

Notes: *1 NMOS open-drain output when P34ODR = 1.

*2 NMOS open-drain output regardless of P34ODR

*3 Simultaneous output of SCK0 and SCK4 cannot be set.

- P33/RxD1/SCL1

The pin function is switched as shown below according to the combination of bit ICE in ICCRA of I²C_0, bit RE in SCR of SCI_1 and bit P33DDR.

ICE	0			1
RE	0		1	—
P33DDR	0	1	—	—
Pin function	P33 input	P33 output* ¹	RxD1 input	SCL1 I/O* ²

Notes: *1 NMOS open-drain output when P33ODR = 1.

*2 NMOS open-drain output regardless of P33ODR

- P32/RxD0/IrRxD/SDA1

The pin function is switched as shown below according to the combination of bit ICE in ICCRA of I²C_0, bit RE in SCR of SCI_0 and bit P32DDR.

ICE	0			1
RE	0		1	—
P32DDR	0	1	—	—
Pin function	P32 input	P32 output* ¹	RxD0/IrRxD input	SDA1 I/O* ²

Notes: *1 NMOS open-drain output when P32ODR = 1.

*2 NMOS open-drain output regardless of P32ODR

- P31/TxD1

The pin function is switched as shown below according to the combination of bit TE in SCR of SCI_1 and bit P31DDR.

TE	0		1
P31DDR	0	1	—
Pin function	P31 input	P31 output*	TxD1 output*

Note: * NMOS open-drain output when P31ODR = 1.

- P30/TxD0/IrTxD

The pin function is switched as shown below according to the combination of bit TE in SCR of SCI_0 and bit P30DDR.

TE	0		1
P30DDR	0	1	—
Pin function	P30 input	P30 output*	TxD0/IrTxD output*

Note: * NMOS open-drain output when P30ODR = 1.

9.4 Port 4

Port 4 is an 8-bit input-only port. Port 4 has the following register.

- Port 4 register (PORT4)

9.4.1 Port 4 Register (PORT4)

PORT4 is an 8-bit read-only register that shows port 4 pin states.

PORT4 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	P47	—*	R	The pin states are always read from this register.
6	P46	—*	R	
5	P45	—*	R	
4	P44	—*	R	
3	P43	—*	R	
2	P42	—*	R	
1	P41	—*	R	
0	P40	—*	R	

Note: * Determined by the states of pins P47 to P40.

9.4.2 Pin Functions

Port 4 also functions as the pins for A/D converter analog input and D/A converter analog output. The correspondence between pins are as follows.

P47/AN7/($\overline{\text{IRQ7}}$)

Pin function	AN7 input
	$\overline{\text{IRQ7}}$ interrupt input*

Note: * $\overline{\text{IRQ7}}$ input when bit ITS7 in ITSr is 1.

P46/AN6/DA0/($\overline{\text{IRQ6}}$)

Pin function	AN6 input
	$\overline{\text{IRQ6}}$ interrupt input*

Note: * $\overline{\text{IRQ6}}$ input when bit ITS6 in ITSr is 1.

P45/AN5/($\overline{\text{IRQ5}}$)

Pin function	AN5 input
	$\overline{\text{IRQ5}}$ interrupt input*

Note: * $\overline{\text{IRQ5}}$ input when bit ITS5 in ITSr is 1.

P44/AN4/($\overline{\text{IRQ4}}$)

Pin function	AN4 input
	$\overline{\text{IRQ4}}$ interrupt input*

Note: * $\overline{\text{IRQ4}}$ input when bit ITS4 in ITSr is 1.

P43/AN3/($\overline{\text{IRQ3}}$)

Pin function	AN3 input
	$\overline{\text{IRQ3}}$ interrupt input*

Note: * $\overline{\text{IRQ3}}$ input when bit ITS3 in ITSr is 1.

P42/AN2/($\overline{\text{IRQ2}}$)

Pin function	AN2 input
	$\overline{\text{IRQ2}}$ interrupt input*

Note: * $\overline{\text{IRQ2}}$ input when bit ITS2 in ITSr is 1.

P41/AN1/($\overline{\text{IRQ1}}$)

Pin function	AN1 input
	$\overline{\text{IRQ1}}$ interrupt input*

Note: * $\overline{\text{IRQ1}}$ input when bit ITS1 in ITSr is 1.

P40/AN0/($\overline{\text{IRQ0}}$)

Pin function	AN0 input
	$\overline{\text{IRQ0}}$ interrupt input*

Note: * $\overline{\text{IRQ0}}$ input when bit ITS0 in ITSr is 1.

9.5 Port 5

Port 5 is a 4-bit I/O port. The port 5 has the following registers.

- Port 5 data direction register (P5DDR)
- Port 5 data register (P5DR)
- Port 5 register (PORT5)

9.5.1 Port 5 Data Direction Register (P5DDR)

The individual bits of P5DDR specify input or output for the pins of port 5.

P5DDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	—	Reserved These bits are always read as 0 and cannot be modified.
3	P53DDR	0	W	When a pin function is specified to a general purpose I/O, setting this bit to 1 makes the corresponding port 1 pin an output pin, while clearing this bit to 0 makes the pin an input pin.
2	P52DDR	0	W	
1	P51DDR	0	W	
0	P50DDR	0	W	

9.5.2 Port 5 Data Register (P5DR)

P5DR stores output data for the port 5 pins.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	—	Reserved These bits are always read as 0 and cannot be modified.
3	P53DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
2	P52DR	0	R/W	
1	P51DR	0	R/W	
0	P50DR	0	R/W	

9.5.3 Port 5 Register (PORT5)

PORT5 shows the pin states. PORT5 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7to 4	—	Undefined	R	Reserved
				Undefined values are read from these bits.
3	P53	—*	R	If bits P53 to P50 are read while P5DDR bits are set to 1, the P5DR values are read. If a port 5 read is performed while P5DDR bits are cleared to 0, the pin states are read.
2	P52	—*	R	
1	P51	—*	R	
0	P50	—*	R	

Note: * Determined by the states of pins P53 to P50.

9.5.4 Pin Functions

Port 5 pins also function as the pins for SCI I/Os, A/D converter inputs, and interrupt inputs. The correspondence between the register specification and the pin functions is shown below.

- $\overline{P53}/\overline{ADTRG}/\overline{IRQ3}$

The pin function is switched as shown below according to the combination of bits TRGS1 and TRGS0 in the A/D control register (ADCR), bit ITS3 in ITSr, and bit P53DDR.

P53DDR	0	1
Pin function	P53 input	P53 output
	\overline{ADTRG} input* ¹	
	$\overline{IRQ3}$ interrupt input* ²	

Notes: *1 \overline{ADTRG} input when TRGS1 = TRGS0 = 1.

*2 $\overline{IRQ3}$ input when ITS3 = 0.

- P52/SCK2/ $\overline{\text{IRQ2}}$

The pin function is switched as shown below according to the combination of bit C/A in SMR of SCI_2, bits CKE0 and CKE1 in SCR, bit ITS2 in ITSR, and bit P52DDR.

CKE1	0				1
C/A	0			1	—
CKE0	0		1	—	—
P52DDR	0	1	—	—	—
Pin function	P52 input	P52 output	SCK2 output	SCK2 output	SCK2 input
	$\overline{\text{IRQ2}}$ interrupt input*				

Note: * $\overline{\text{IRQ2}}$ input when ITS2 = 0.

- P51/RxD2/ $\overline{\text{IRQ1}}$

The pin function is switched as shown below according to the combination of bit RE in SCR of SCI_2, bit ITS1 in ITSR, and bit P51DDR.

RE	0		1
P51DDR	0	1	—
Pin function	P51 input	P51 output	RxD2 input
	$\overline{\text{IRQ1}}$ interrupt input*		

Note: * $\overline{\text{IRQ1}}$ input when ITS1 = 0.

- P50/TxD2/ $\overline{\text{IRQ0}}$

The pin function is switched as shown below according to the combination of bit TE in SCR of SCI_2, bit ITS0 in ITSR, and bit P50DDR.

TE	0		1
P50DDR	0	1	—
Pin function	P50 input	P50 output	TxD2 input
	$\overline{\text{IRQ0}}$ interrupt input*		

Note: * $\overline{\text{IRQ0}}$ input when ITS0 = 0.

9.6 Port 8

Port 8 is a 6-bit I/O port that also has other functions. The port 8 has the following registers.

- Port 8 data direction register (P8DDR)
- Port 8 data register (P8DR)
- Port 8 register (PORT8)

9.6.1 Port 8 Data Direction Register (P8DDR)

The individual bits of P8DDR specify input or output for the pins of port 8.

P8DDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	P85DDR	0	W	When a pin function is specified to a general purpose I/O, setting bit 5, 3, or 1 makes the corresponding port 1 pin an output pin, while clearing this bit to 0 makes the pin an input pin.
4	—	0	—	
3	P83DDR	0	W	
2	—	0	—	Bits 4, 2, and 0 are reserved.
1	P81DDR	0	W	
0	—	0	—	

9.6.2 Port 8 Data Register (P8DR)

P8DR stores output data for the port 8 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	These bits are always read as 0 and cannot be modified.
5	P85DR	0	R/W	Bits 5, 3, and 1 store output data when the pin function is specified to a general purpose I/O. Bits 4, 2, and 0 are reserved.
4	—	0	—	
3	P83DR	0	R/W	
2	—	0	—	
1	P81DR	0	R/W	
0	—	0	—	

9.6.3 Port 8 Register (PORT8)

PORT8 shows the pin states.

PORT8 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	—	Undefined	—	Reserved
6	—	Undefined	—	These bits are reserved, if read they will return an undefined value.
5	P85	—*	R	If a port 8 read is performed while P8DDR bits are set to 1, the P8DR values are read. If a port 8 read is performed while P8DDR bits are cleared to 0, the pin states are read.
4	—	Undefined	R	
3	P83	—*	R	
2	—	Undefined	R	Bits 4, 2, and 0 are reserved.
1	P81	—*	R	
0	—	Undefined	R	

Note: * Determined by the states of pins P85, P83 and P81.

9.6.4 Pin Functions

Port 8 pins also function as interrupt inputs and SCI_3 I/Os. The correspondence between the register specification and the pin functions is shown below.

- P85/SCK3

The pin function is switched as shown below according to the combination of bit C/\bar{A} in SMR in SCI_3, bits CKE0 and CKE1 in SCR, and bit P85DDR.

CKE1	0			1
C/\bar{A}	0		1	—
CKE0	0	1	—	—
P85DDR	0	1	—	—
Pin function	P85 input	P85 output	SCK3 output	SCK3 input

- P83/RxD3

The pin function is switched as shown below according to the combination of bit RE in SCR of SCI_3, and bit P83DDR.

RE	0		1
P83DDR	0	1	—
Pin function	P83 input	P83 output	RxD3 input

- P81/TxD3

The pin function is switched as shown below according to the combination of bit TE in SCR of SCI_3, and bit P81DDR.

TE	0		1
P81DDR	0	1	—
Pin function	P81 input	P81 output	TxD3 output

9.7 Port 9

Port 9 is a 2-bit input-only port. Port 9 has the following register.

- Port 9 register (PORT9)

9.7.1 Port 9 Register (PORT9)

PORT9 is an 8-bit read-only register that shows port 4 pin states.

PORT9 cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	—	Undefined	R	Reserved
6	—	Undefined	R	If read they will return an undefined value.
5	P95	—*	R	The pin states are always read when a port 9 read is performed.
4	P94	—*	R	
3	—	Undefined	R	Reserved
2	—	Undefined	R	If read they will return an undefined value.
1	—	Undefined	R	
0	—	Undefined	R	

Note: * Determined by the states of pins P95 and P94.

9.7.2 Pin Functions

Port 9 also functions as the pins for A/D converter analog input and D/A converter analog output. The correspondence between pins are as follows.

P95/AN13/DA3

Pin function	AN13 input
	DA3 output

P94/AN12/DA2

Pin function	AN12 input
	DA2 output

9.8 Port A

Port A is an 8-bit I/O port that also has other functions. The port A has the following registers.

- Port A data direction register (PADDR)
- Port A data register (PADR)
- Port A register (PORTA)
- Port A MOS zcontrol register (PAPCR)
- Port A open-drain control register (PAODR)
- Port function control register 0 (PFCR0)
- Port function control register 1 (PFCR1)

9.8.1 Port A Data Direction Register (PADDR)

The individual bits of PADDR specify input or output for the pins of port A. PADDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7DDR	0	W	<ul style="list-style-type: none">Modes 1 and 2
6	PA6DDR	0	W	Pins PA4 to PA0 are address outputs.
5	PA5DDR	0	W	For pins PA6 and PA5, when the corresponding A22E and A21E bits are set to 1, setting a PADDR bit to 1 makes the corresponding port A pin an address output, while clearing the bit to 0 makes the pin an input port. Clearing A22E and A21E bits to 0 makes the corresponding port A pin an I/O port, and its function can be switched with PADDR. For pin PA7, when the A23E bit is set to 1, setting the PA7DDR bit to 1 makes the pin an address output, while clearing the bit to 0 makes the pin an input port. When the CS7E bit is set to 1 while the A23E bit is cleared to 0, pin PA7 functions as the $\overline{CS7}$ output pin when PA7DDR is set to 1, and as an input port when the bit is cleared to 0. When the CS7E bit is cleared to 0, pin PA7 is an I/O port, and its function can be switched with PA7DDR.
4	PA4DDR	0	W	
3	PA3DDR	0	W	
2	PA2DDR	0	W	
1	PA1DDR	0	W	
0	PA0DDR	0	W	<ul style="list-style-type: none">Modes 4 and 7 (when EXPE = 1) <p>For pins PA6 to PA0, when the corresponding A22E to A16E bits are set to 1, setting a PADDR bit to 1 makes the corresponding port A pin an address output, while clearing the bit to 0 makes the pin an input port. Clearing A22E to A21E bits to 0 makes the corresponding port A pin an I/O port, and its function can be switched with PADDR. For pin PA7, when the A23E bit is set to 1, setting the PA7DDR bit to 1 makes the pin an address output, while clearing the bit to 0 makes the pin an input port. When the CS7E bit is set to 1 while the A23E bit is cleared to 0, pin PA7 functions as the $\overline{CS7}$ output pin when PA7DDR is set to 1, and as an input port when the bit is cleared to 0. When the CS7E bit is cleared to 0, pin PA7 is an I/O port, and its function can be switched with PA7DDR.</p> <ul style="list-style-type: none">Mode 7 (when EXPE = 0) <p>Port A is an I/O port, and its pin functions can be switched with PADDR.</p>

9.8.2 Port A Data Register (PADR)

PADR stores output data for the port A pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	PA6DR	0	R/W	
5	PA5DR	0	R/W	
4	PA4DR	0	R/W	
3	PA3DR	0	R/W	
2	PA2DR	0	R/W	
1	PA1DR	0	R/W	
0	PA0DR	0	R/W	

9.8.3 Port A Register (PORTA)

PORTA shows port A pin states.

PORTA cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7	—*	R	If a port A read is performed while PADDR bits are set to 1, the PADR values are read. If a port A read is performed while PADDR bits are cleared to 0, the pin states are read.
6	PA6	—*	R	
5	PA5	—*	R	
4	PA4	—*	R	
3	PA3	—*	R	
2	PA2	—*	R	
1	PA1	—*	R	
0	PA0	—*	R	

Note: * Determined by the states of pins PA7 to PA0.

9.8.4 Port A MOS Pull-Up Control Register (PAPCR)

PAPCR controls the MOS input pull-up function. Bits 7 to 5 are valid in modes 1 and 2 and all the bits are valid in modes 4 and 7.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7PCR	0	R/W	When PADDR = 0 (input port), setting the corresponding bit to 1 turns on the MOS input pull-up for that pin.
6	PA6PCR	0	R/W	
5	PA5PCR	0	R/W	
4	PA4PCR	0	R/W	
3	PA3PCR	0	R/W	
2	PA2PCR	0	R/W	
1	PA1PCR	0	R/W	
0	PA0PCR	0	R/W	

9.8.5 Port A Open Drain Control Register (PAODR)

PAODR specifies an output type of port A.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7ODR	0	R/W	When not specified for address output, setting the corresponding bit to 1 specifies a pin output type to NMOS open-drain output, while clearing this bit to 0 specifies that to CMOS output.
6	PA6ODR	0	R/W	
5	PA5ODR	0	R/W	
4	PA4ODR	0	R/W	
3	PA3ODR	0	R/W	
2	PA2ODR	0	R/W	
1	PA1ODR	0	R/W	
0	PA0ODR	0	R/W	

9.8.6 Port Function Control Register 0 (PFCR0)

PFCR0 controls the I/O port.

Bit	Bit Name	Initial Value	R/W	Description
7	CS7E	1	R/W	$\overline{CS7}$ to $\overline{CS0}$ enable
6	CS6E	1	R/W	Enable/disable corresponding \overline{CSn} output.
5	CS5E	1	R/W	0: Set as I/O port.
4	CS4E	1	R/W	1: Set as \overline{CSn} output pin.
3	CS3E	1	R/W	(n = 7 to 0)
2	CS2E	1	R/W	
1	CS1E	1	R/W	
0	CS0E	1	R/W	

9.8.7 Port Function Control Register 1 (PFCR1)

PFCR1 performs I/O port control. Bits 7 to 5 are valid in modes 1 and 2 and all the bits are valid in modes 4 and 7.

Bit	Bit Name	Initial Value	R/W	Description
7	A23E	1	R/W	Address 23 Enable Enables or disables output for address output 23 (A23). 0: DR output when PA7DDR = 1 1: A23 output when PA7DDR = 1
6	A22E	1	R/W	Address 22 Enable Enables or disables output for address output 22 (A22). 0: DR output when PA6DDR = 1 1: A22 output when PA6DDR = 1
5	A21E	1	R/W	Address 21 Enable Enables or disables output for address output 21 (A21). 0: DR output when PA5DDR = 1 1: A21 output when PA5DDR = 1
4	A20E	1	R/W	Address 20 Enable Enables or disables output for address output 20 (A20). 0: DR output when PA4DDR = 1 1: A20 output when PA4DDR = 1

Bit	Bit Name	Initial Value	R/W	Description
3	A19E	1	R/W	Address 19 Enable Enables or disables output for address output 19 (A19). 0: DR output when PA3DDR = 1 1: A19 output when PA3DDR = 1
2	A18E	1	R/W	Address 18 Enable Enables or disables output for address output 18 (A18). 0: DR output when PA2DDR = 1 1: A18 output when PA2DDR = 1
1	A17E	1	R/W	Address 17 Enable Enables or disables output for address output 17 (A17). 0: DR output when PA1DDR = 1 1: A17 output when PA1DDR = 1
0	A16E	1	R/W	Address 16 Enable Enables or disables output for address output 16 (A16). 0: DR output when PA0DDR = 1 1: A16 output when PA0DDR = 1

9.8.8 Pin Functions

Port A pins also function as the pins for address outputs and interrupt inputs. The correspondence between the register specification and the pin functions is shown below.

- PA7/A23/ $\overline{\text{CS7}}$ / $\overline{\text{IRQ7}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bits A23E and CS7E, bits ITS7 to ITS5 in ITSr, and bit PA7DDR.

Operating mode	1, 2, 4						7							
EXPE	—						0	1						
A23E	0			1			—	0				1		
CS7E	0		1		—		—	0			1		—	
PADDR	0	1	0	1	0	1	0	1	0		1		0	1
Pin function	PA input	PA output	PA input	CS7 output	PA output	Address output	PA input	PA output	PA input	PA output	PA input	CS7 output	PA input	Address output
$\overline{\text{IRQ7}}$ interrupt input*														

Note: * $\overline{\text{IRQ7}}$ input when ITS7 = 0.

- PA6/A22/ $\overline{\text{IRQ6}}$, PA5/A21/ $\overline{\text{IRQ5}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bits A22E and A21E, bits IS6 and ITS5 in ITSr, and bit PAnDDR.

Operating mode	1, 2, 4				7					
EXPE	—				0		1			
AxxE	0		1		—		0		1	
PADDR	0	1	0	1	0	1	0	1	0	1
Pin function	PA input	PA output	PA input	Address output	PA input	PA output	PA input	PA output	PA input	Address output
	$\overline{\text{IRQn}}$ interrupt input*									

n = 6 or 5 xx = 22 or 21

Note: * $\overline{\text{IRQn}}$ input when ITS_n = 0.

- PA4/A20/ $\overline{\text{IRQ4}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit A20E and bit PA4DDR.

Operating mode	1, 2	4				7					
EXPE	—	—				0		1			
A20E	—	0		1		—		0		1	
PA4DDR	—	0	1	0	1	0	1	0	1	0	1
Pin function	A20 output	PA4 input	PA4 output	PA4 input	A20 output	PA4 input	PA4 output	PA4 input	PA4 output	PA4 input	A20 output
	$\overline{\text{IRQ4}}$ interrupt input*										

Note: * $\overline{\text{IRQ4}}$ input when ITS₄ = 0.

- PA3/A19, PA2/A18, PA1/A17, PA0/A16

The pin function is switched as shown below according to the operating mode, bit EXPE, bits A19E to A16E, and bit PADDR.

Operating mode	1, 2	4				7					
EXPE	—	—				0		1			
AxxE	—	0		1		—		0		1	
PAnDDR	—	0	1	0	1	0	1	0	1	0	1
Pin function	Address output	PA input	PA output	PA input	Address output	PA input	PA output	PA input	PA output	PA input	Address output

xx = 19 to 16 n = 3 to 0

9.8.9 Port A MOS Input Pull-Up States

Port A has a built-in MOS input pull-up function that can be controlled by software. This MOS input pull-up function can be used by pins PA7 to PA5 in modes 1 and 2 and by all pins in modes 4 and 7. MOS input pull-up can be specified as on or off on a bit-by-bit basis.

Table 9.2 summarizes the MOS input pull-up states.

Table 9.2 MOS Input Pull-Up States (Port A)

Mode		Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
4, 7	PA7 to PA0	Off	Off	On/Off	On/Off
1, 2	PA7 to PA5			On/Off	On/Off
	PA4 to PA0			Off	Off

Legend:

Off: MOS input pull-up is always off.

On/Off: On when PADDR = 0 and PAPCR = 1; otherwise off.

9.9 Port B

Port B is an 8-bit I/O port that also has other functions. The port B has the following registers.

- Port B data direction register (PBDDR)
- Port B data register (PBDR)
- Port B register (PORTB)
- Port B MOS pull-up control register (PBPCR)

9.9.1 Port B Data Direction Register (PBDDR)

The individual bits of PBDDR specify input or output for the pins of port B.

PBDDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7DDR	0	W	<ul style="list-style-type: none">• Modes 1 and 2 Port B pins are address outputs regardless of the PBDDR settings.
6	PB6DDR	0	W	
5	PB5DDR	0	W	
4	PB4DDR	0	W	<ul style="list-style-type: none">• Modes 4 and 7 (when EXPE = 1) Setting a PBDDR bit to 1 makes the corresponding port B pin an address output, while clearing the bit to 0 makes the pin an input port.
3	PB3DDR	0	W	
2	PB2DDR	0	W	
1	PB1DDR	0	W	<ul style="list-style-type: none">• Mode 7 (when EXPE = 0) Port B is an I/O port, and its pin functions can be switched with PBDDR.
0	PB0DDR	0	W	

9.9.2 Port B Data Register (PBDR)

PBDR is stores output data for the port B pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7DR	0	R/W	An output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	PB6DR	0	R/W	
5	PB5DR	0	R/W	
4	PB4DR	0	R/W	
3	PB3DR	0	R/W	
2	PB2DR	0	R/W	
1	PB1DR	0	R/W	
0	PB0DR	0	R/W	

9.9.3 Port B Register (PORTB)

PORTB shows port B pin states. PORTB cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7	—*	R	If this register is read is while PBDDR bits are set to 1, the PBDR values are read. If a port B read is performed while PBDDR bits are cleared to 0, the pin states are read.
6	PB6	—*	R	
5	PB5	—*	R	
4	PB4	—*	R	
3	PB3	—*	R	
2	PB2	—*	R	
1	PB1	—*	R	
0	PB0	—*	R	

Note: * Determined by the states of pins PB7 to PB0.

9.9.4 Port B MOS Pull-Up Control Register (PBPCR)

PBPCR controls the on/off state of MOS input pull-up of port B. PBPCR is valid in modes 4 and 7.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7PCR	0	R/W	When PBDDR = 0 (input port), setting the corresponding bit to 1 turns on the MOS input pull-up for that pin.
6	PB6PCR	0	R/W	
5	PB5PCR	0	R/W	
4	PB4PCR	0	R/W	
3	PB3PCR	0	R/W	
2	PB2PCR	0	R/W	
1	PB1PCR	0	R/W	
0	PB0PCR	0	R/W	

9.9.5 Pin Functions

Port B pins also function as the pins for address outputs. The correspondence between the register specification and the pin functions is shown below.

- PB7/A15, PB6/A14, PB5/A13, PB4/A12, PB3/A11, PB2/A10, PB1/A9, PB0/A8

The pin function is switched as shown below according to the operating mode, bit EXPE, and bit PBDDR.

Operating mode	1, 2	4		7			
EXPE	—	—		0		1	
PBDDR	—	0	1	0	1	0	1
Pin function	Address output	PB input	Address output	PB input	PB output	PB input	Address output

9.9.6 Port B MOS Input Pull-Up States

Port B has a built-in MOS input pull-up function that can be controlled by software. This MOS input pull-up function can be used in modes 4 and 7. MOS input pull-up can be specified as on or off on a bit-by-bit basis.

In modes 4 and 7, when a PBDDR bit is cleared to 0, setting the corresponding PBPCR bit to 1 turns on the MOS input pull-up for that pin.

Table 9.3 summarizes the MOS input pull-up states.

Table 9.3 MOS Input Pull-Up States (Port B)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2	Off	Off	Off	Off
4, 7			On/Off	On/Off

Legend:

Off: MOS input pull-up is always off.

On/Off: On when PBDDR = 0 and PBPCR = 1; otherwise off.

9.10 Port C

Port C is an 8-bit I/O port that also has other functions. The port C has the following registers.

- Port C data direction register (PCDDR)
- Port C data register (PCDR)
- Port C register (PORTC)
- Port C MOS pull-up control register (PCPCR)

9.10.1 Port C Data Direction Register (PCDDR)

The individual bits of PCDDR specify input or output for the pins of port C.

PCDDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	PC7DDR	0	W	<ul style="list-style-type: none">• Modes 1 and 2 Port C pins are address outputs regardless of the PCDDR settings.
6	PC6DDR	0	W	
5	PC5DDR	0	W	
4	PC4DDR	0	W	<ul style="list-style-type: none">• Modes 4 and 7 (when EXPE = 1) Setting a PCDDR bit to 1 makes the corresponding port C pin an address output, while clearing the bit to 0 makes the pin an input port.
3	PC3DDR	0	W	
2	PC2DDR	0	W	
1	PC1DDR	0	W	<ul style="list-style-type: none">• Mode 7 (when EXPE = 0) Port C is an I/O port, and its pin functions can be switched with PCDDR.
0	PC0DDR	0	W	

9.10.2 Port C Data Register (PCDR)

PCDR stores output data for the port C pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PC7DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	PC6DR	0	R/W	
5	PC5DR	0	R/W	
4	PC4DR	0	R/W	
3	PC3DR	0	R/W	
2	PC2DR	0	R/W	
1	PC1DR	0	R/W	
0	PC0DR	0	R/W	

9.10.3 Port C Register (PORTC)

PORTC is shows port C pin states.

PORTC cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	PC7	—*	R	If a port C read is performed while PCDDR bits are set to 1, the PCDR values are read. If a port C read is performed while PCDDR bits are cleared to 0, the pin states are read.
6	PC6	—*	R	
5	PC5	—*	R	
4	PC4	—*	R	
3	PC3	—*	R	
2	PC2	—*	R	
1	PC1	—*	R	
0	PC0	—*	R	

Note: * Determined by the states of pins PC7 to PC0.

9.10.4 Port C MOS Pull-Up Control Register (PCPCR)

PCPCR controls the on/off state of MOS input pull-up of port C. PCPCR is valid in modes 4 and 7.

Bit	Bit Name	Initial Value	R/W	Description
7	PC7PCR	0	R/W	When PCDDR = 0 (input port), setting the corresponding bit to 1 turns on the MOS input pull-up for that pin.
6	PC6PCR	0	R/W	
5	PC5PCR	0	R/W	
4	PC4PCR	0	R/W	
3	PC3PCR	0	R/W	
2	PC2PCR	0	R/W	
1	PC1PCR	0	R/W	
0	PC0PCR	0	R/W	

9.10.5 Pin Functions

Port C pins also function as the pins for address outputs. The correspondence between the register specification and the pin functions is shown below.

- PC7/A7, PC6/A6, PC5/A5, PC4/A4, PC3/A3, PC2/A2, PC1/A1, PC0/A0

The pin function is switched as shown below according to the operating mode, bit EXPE, and bit PCDDR.

Operating mode	1, 2	4		7			
EXPE	—	—		0		1	
PCDDR	—	0	1	0	1	0	1
Pin function	Address output	PC input	Address output	PC input	PC output	PC input	Address output

9.10.6 Port C MOS Input Pull-Up States

Port C has a built-in MOS input pull-up function that can be controlled by software. This MOS input pull-up function can be used in modes 4 and 7. MOS input pull-up can be specified as on or off on a bit-by-bit basis.

In modes 4 and 7, when a PCDDR bit is cleared to 0, setting the corresponding PCPCR bit to 1 turns on the MOS input pull-up for that pin.

Table 9.4 summarizes the MOS input pull-up states.

Table 9.4 MOS Input Pull-Up States (Port C)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2	Off	Off	Off	Off
4, 7			On/Off	On/Off

Legend:

Off: MOS input pull-up is always off.

On/Off: On when PCDDR = 0 and PCPCR = 1; otherwise off.

9.11 Port D

Port D is an 8-bit I/O port that also has other functions. The port D has the following registers.

- Port D data direction register (PDDDR)
- Port D data register (PDDR)
- Port D register (PORTD)
- Port D MOS pull-up control register (PDPCR)

9.11.1 Port D Data Direction Register (PDDDR)

The individual bits of PDDDR specify input or output for the pins of port D.

PDDDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	PD7DDR	0	W	<ul style="list-style-type: none">• Modes 1, 2, 4, and 7 (when EXPE = 1) Port D is automatically designated for data input/output.
6	PD6DDR	0	W	
5	PD5DDR	0	W	
4	PD4DDR	0	W	<ul style="list-style-type: none">• Mode 7 (when EXPE = 0) Port D is an I/O port, and its pin functions can be switched with PDDDR.
3	PD3DDR	0	W	
2	PD2DDR	0	W	
1	PD1DDR	0	W	
0	PD0DDR	0	W	

9.11.2 Port D Data Register (PDDR)

PDDR stores output data for the port D pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PD7DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	PD6DR	0	R/W	
5	PD5DR	0	R/W	
4	PD4DR	0	R/W	
3	PD3DR	0	R/W	
2	PD2DR	0	R/W	
1	PD1DR	0	R/W	
0	PD0DR	0	R/W	

9.11.3 Port D Register (PORTD)

PORTD shows port D pin states.

PORTD cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	PD7	—*	R	If a port D read is performed while PDDDR bits are set to 1, the PDDR values are read. If a port D read is performed while PDDDR bits are cleared to 0, the pin states are read.
6	PD6	—*	R	
5	PD5	—*	R	
4	PD4	—*	R	
3	PD3	—*	R	
2	PD2	—*	R	
1	PD1	—*	R	
0	PD0	—*	R	

Note: * Determined by the states of pins PD7 to PD0.

9.11.4 Port D Pull-up Control Register (PDPCR)

PDPCR controls on/off states of the input pull-up MOS of port D. PDPCR is valid in mode 7.

Bit	Bit Name	Initial Value	R/W	Description
7	PD7PCR	0	R/W	When PDDDR = 0 (input port), the input pull-up MOS of the input pin is on when the corresponding bit is set to 1.
6	PD6PCR	0	R/W	
5	PD5PCR	0	R/W	
4	PD4PCR	0	R/W	
3	PD3PCR	0	R/W	
2	PD2PCR	0	R/W	
1	PD1PCR	0	R/W	
0	PD0PCR	0	R/W	

9.11.5 Pin Functions

Port D pins also function as the pins for data I/Os. The correspondence between the register specification and the pin functions is shown below.

- PD7/D15, PD6/D14, PD5/D13, PD4/D12, PD3/D11, PD2/D10, PD1/D9, PD0/D8

The pin function is switched as shown below according to the operating mode, bit EXPE, and bit PDDDR.

Operating mode	1, 2, 4	7		
EXPE	—	0		1
PDDDR	—	0	1	—
Pin function	Data I/O	PD input	PD output	Data I/O

9.11.6 Port D MOS Input Pull-Up States

Port D has a built-in MOS input pull-up function that can be controlled by software. This MOS input pull-up function can be used in mode 7. MOS input pull-up can be specified as on or off on a bit-by-bit basis.

In mode 7, when a PDDDR bit is cleared to 0, setting the corresponding PDPCR bit to 1 turns on the MOS input pull-up for that pin.

Table 9.5 summarizes the MOS input pull-up states.

Table 9.5 MOS Input Pull-Up States (Port D)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2, 4	Off	Off	Off	Off
7			On/Off	On/Off

Legend:

OFF: MOS input pull-up is always off.

On/Off: On when PDDDR = 0 and PDPCR = 1; otherwise off.

9.12 Port E

Port E is an 8-bit I/O port that also has other functions. The port E has the following registers.

- Port E data direction register (PEDDDR)
- Port E data register (PEDR)
- Port E register (PORTE)
- Port E MOS pull-up control register (PEPCR)

9.12.1 Port E Data Direction Register (PEDDDR)

The individual bits of PEDDDR specify input or output for the pins of port E.

PEDDDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	PE7DDR	0	W	<ul style="list-style-type: none">• Modes 1, 2, and 4
6	PE6DDR	0	W	When 8-bit bus mode is selected, port E functions as an I/O port. The pin states can be changed with PEDDDR.
5	PE5DDR	0	W	
4	PE4DDR	0	W	When 16-bit bus mode is selected, port E is designated for data input/output.
3	PE3DDR	0	W	
2	PE2DDR	0	W	For details on 8-bit and 16-bit bus modes, see section 6, Bus Controller.
1	PE1DDR	0	W	
0	PE0DDR	0	W	<ul style="list-style-type: none">• Mode 7 (when EXPE = 1) When 8-bit bus mode is selected, port E functions as an I/O port. Setting a PEDDDR bit to 1 makes the corresponding port E pin an output port, while clearing the bit to 0 makes the pin an input port. When 16-bit bus mode is selected, port E is designated for data input/output.• Mode 7 (when EXPE = 0) Port E is an I/O port, and its pin functions can be switched with PEDDDR.

9.12.2 Port E Data Register (PEDR)

PEDR stores output data for the port E pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PE7DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	PE6DR	0	R/W	
5	PE5DR	0	R/W	
4	PE4DR	0	R/W	
3	PE3DR	0	R/W	
2	PE2DR	0	R/W	
1	PE1DR	0	R/W	
0	PE0DR	0	R/W	

9.12.3 Port E Register (PORTE)

PORTE shows port E pin states.

PORTE cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	PE7	—*	R	If a port E read is performed while PEDDR bits are set to 1, the PEDR values are read. If a port E read is performed while PEDDR bits are cleared to 0, the pin states are read.
6	PE6	—*	R	
5	PE5	—*	R	
4	PE4	—*	R	
3	PE3	—*	R	
2	PE2	—*	R	
1	PE1	—*	R	
0	PE0	—*	R	

Note: * Determined by the states of pins PE7 to PE0.

9.12.4 Port E Pull-up Control Register (PEPCR)

PEPCR controls on/off states of the input pull-up MOS of port E. PEPCR is valid in 8-bit bus mode.

Bit	Bit Name	Initial Value	R/W	Description
7	PE7PCR	0	R/W	When PEDDR = 0 (input port), the input pull-up MOS of the input pin is on when the corresponding bit is set to 1.
6	PE6PCR	0	R/W	
5	PE5PCR	0	R/W	
4	PE4PCR	0	R/W	
3	PE3PCR	0	R/W	
2	PE2PCR	0	R/W	
1	PE1PCR	0	R/W	
0	PE0PCR	0	R/W	

9.12.5 Pin Functions

Port E pins also function as the pins for data I/Os. The correspondence between the register specification and the pin functions is shown below.

- PE7/D7, PE6/D6, PE5/D5, PE4/D4, PE3/D3, PE2/D2, PE1/D1, PE0/D0

The pin function is switched as shown below according to the operating mode, bus mode, bit EXPE, and bit PEDDR.

Operating mode	1, 2, 4			7				
Bus mode	All areas 8-bit space		At least one area 16-bit space	—		All areas 8-bit space		At least one area 16-bit space
EXPE	—		—	0		1		1
PEDDR	0	1	—	0	1	0	1	—
Pin function	PE input	PE output	Data I/O	PE input	PE output	PE input	PE output	Data I/O

9.12.6 Port E MOS Input Pull-Up States

Port E has a built-in MOS input pull-up function that can be controlled by software. This MOS input pull-up function can be used in 8-bit bus mode. MOS input pull-up can be specified as on or off on a bit-by-bit basis. In 8-bit bus mode, when a PEDDR bit is cleared to 0, setting the corresponding PEPCR bit to 1 turns on the MOS input pull-up for that pin.

Table 9.6 summarizes the MOS input pull-up states.

Table 9.6 MOS Input Pull-Up States (Port E)

Mode		Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2, and 4	8-bit bus	Off	Off	On/Off	On/Off
	16-bit bus			Off	Off

Legend:

Off: MOS input pull-up is always off.

On/Off: On when PEDDR = 0 and PEPCR = 1; otherwise off.

9.13 Port F

Port F is an 8-bit I/O port that also has other functions. The port F has the following registers. For details on the port function control register 0, refer to section 9.8.6, Port Function Control Register 0 (PFCR0), and for details on the port function control register 2, refer to section 9.3.5, Port Function Control Register 2 (PFCR2).

- Port F data direction register (PFDDR)
- Port F data register (PFDR)
- Port F register (PORTF)
- Port Function Control Register 0 (PFCR0)
- Port Function Control Register 2 (PFCR2)

9.13.1 Port F Data Direction Register (PFDDR)

The individual bits of PFDDR specify input or output for the pins of port F. PFDDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	PF7DDR	1/0* ¹	W	<ul style="list-style-type: none">Modes 1, 2, 4, and 7 (when EXPE = 1)
6	PF6DDR	0	W	Pin PF7 functions as the ϕ output pin when the corresponding PFDDR bit is set to 1, and as an input port when the bit is cleared to 0.
5	PF5DDR	0	W	
4	PF4DDR	0	W	Pin PF6 functions as the \overline{AS} output pin when ASOE is set to 1. When ASOE is cleared to 0, pin PF6 is an I/O port and its function can be switched with PF6DDR.
3	PF3DDR	0	W	
2	PF2DDR	0	W	
1	PF1DDR	0	W	Pins PF5 and PF4 are automatically designated as bus control outputs (RD and HWR).
0	PF0DDR	0	W	Pin PF3 functions as the \overline{LWR} output pin when LWROE is set to 1. When LWROE is cleared to 0, pin PF3 is an I/O port and its function can be switched with PF3DDR. Pins PF2 and PF1 function as bus control output pins (\overline{LCAS} * ² and \overline{UCAS} * ²) when the appropriate bus controller settings are made. When the \overline{CS} output enable bits ($\overline{CS6E}$ and $\overline{CS5E}$) are set to 1, they function as \overline{CS} outputs. When the \overline{CS} output enable bits ($\overline{CS6E}$ and $\overline{CS5E}$) are cleared to 0, pins PF2 and PF1 are I/O ports and their functions can be switched with the corresponding PFDDR bits. Pin PF0 functions as a bus control input pin (\overline{WAIT}) when the appropriate bus controller settings are made. Otherwise, this pin is an output port when the corresponding PFDDR bit is set to 1, and an input port when the bit is cleared to 0. <ul style="list-style-type: none">Mode 7 (when EXPE = 0) Pin PF7 functions as the ϕ output pin when the corresponding PFDDR bit is set to 1, and as an input port when the bit is cleared to 0. Pins PF6 to PF0 are I/O ports, and their functions can be switched with PFDDR.

Notes: *1 PF7DDR is initialized to 1 in modes 1, 2, and 4, and to 0 in mode 7.

*2 Not supported by the H8S/2366.

9.13.2 Port F Data Register (PFDR)

PFDR stores output data for the port F pins.

Bit	Bit Name	Initial Value	R/W	Description
7	PF7DR	0	R/W	Output data for a pin is stored when the pin function is specified to a general purpose I/O.
6	PF6DR	0	R/W	
5	PF5DR	0	R/W	
4	PF4DR	0	R/W	
3	PF3DR	0	R/W	
2	PF2DR	0	R/W	
1	PF1DR	0	R/W	
0	PF0DR	0	R/W	

9.13.3 Port F Register (PORTF)

PORTF shows port F pin states.

PORTF cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	PF7	—*	R	If a port F read is performed while PFDDR bits are set to 1, the PFDR values are read. If a port F read is performed while PFDDR bits are cleared to 0, the pin states are read.
6	PF6	—*	R	
5	PF5	—*	R	
4	PF4	—*	R	
3	PF3	—*	R	
2	PF2	—*	R	
1	PF1	—*	R	
0	PF0	—*	R	

Note: * Determined by the states of pins PF7 to PF0.

9.13.4 Pin Functions

Port F pins also function as the pins for external interrupt inputs, bus control signal I/Os, and system clock outputs (ϕ). The correspondence between the register specification and the pin functions is shown below.

- PF7/ ϕ

The pin function is switched as shown below according to bit PF7DDR.

Operating mode	1, 2, 4, 7	
PFDDR	0	1
Pin function	PF7 input	ϕ output

- PF6/ $\overline{\text{AS}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit ASOE, and bit PF6DDR.

Operating mode	1, 2, 4			7				
EXPE	—			0		1		
ASOE	1	0		—		1	0	
PF6DDR	—	0	1	0	1	—	0	1
Pin function	AS output	PF6 input	PF6 output	PF6 input	PF6 output	AS output	PF6 input	PF6 output

- PF5/ $\overline{\text{RD}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, and bit PF5DDR.

Operating mode	1, 2, 4		7			
EXPE	—		0			1
PF5DDR	—		0	1		—
Pin function	$\overline{\text{RD}}$ output		PF5 input	PF5 output		$\overline{\text{RD}}$ output

- PF4/ $\overline{\text{HWR}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, and bit PF4DDR.

Operating mode	1, 2, 4	7		
EXPE	—	0		1
PF4DDR	—	0	1	—
Pin function	$\overline{\text{HWR}}$ output	PF4 input	PF4 output	$\overline{\text{HWR}}$ output

- PF3/ $\overline{\text{LWR}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit LWROE, and bit PF3DDR.

Operating mode	1, 2, 4			7				
EXPE	—			0		1		
LWROD	1	0		—		1	0	
PF3DDR	—	0	1	0	1	—	0	1
Pin function	$\overline{\text{LWR}}$ output	PF3 input	PF3 output	PF3 input	PF3 output	$\overline{\text{LWR}}$ output	PF3 input	PF3 output

- $\overline{\text{PF2}}/\overline{\text{CS6}}/\overline{\text{LCAS}}^*$

The pin function is switched as shown below according to the combination of the operating mode, bit EXPE, bits RMTS2 to RMTS0* in DRAMCR, bits ABW5 to ABW2 in ABWCR, and bit PF2DDR.

Operating mode	1, 2, 4						3, 7					
EXPE	—						0		1			
Areas 2 to 5	Any DRAM* space area is 16-bit bus space	All DRAM* space areas are 8-bit bus space, or areas 2 to 5 are all normal space					—		Any DRAM* space area is 16-bit bus space	All DRAM* space areas are 8-bit bus space, or areas 2 to 5 are all normal space		
CS6E	—	1		0		—		—	1		0	
PF2DDR	—	0	1	0	1	0	1	—	0	1	0	1
Pin function	$\overline{\text{LCAS}}^*$ output	PF2 input	$\overline{\text{CS6}}$ output	PF2 input	PF2 output	PF2 input	PF2 output	$\overline{\text{LCAS}}^*$ output	PF2 input	$\overline{\text{CS6}}$ output	PF2 input	PF2 output

Note: * Not supported by the H8S/2366.

- $\overline{\text{PF1}}/\overline{\text{CS5}}/\overline{\text{UCAS}}^*$

The pin function is switched as shown below according to the combination of the operating mode, bit EXPE, bits RMTS2 to RMTS0* in DRAMCR, and bit PF1DDR.

Operating mode	1, 2, 4			7				
EXPE	—			0		1		
Areas 2 to 5	Any of areas 2 to 5 is DRAM*/synchronous DRAM space	Areas 2 to 5 are all normal space		—		Any of areas 2 to 5 is DRAM* space	Areas 2 to 5 are all normal space	
PF1DDR	—	0	1	0	1	—	0	1
Pin function	UCAS* output	PF1 input	PF1 output	PF1 input	PF1 output	UCAS* output	PF1 input	PF1 output

Note: * Not supported by the H8S/2366.

- PF0/ $\overline{\text{WAIT}}$ / $\overline{\text{OE}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit WAITE, bit OEE in DRAMCR, bit OES in PFCR2, and bit PF0DDR.

Operating mode	1, 2, 4						7							
EXPE	—						0		1					
OEE*	0		1				—		0		1			
OES*	—		0			1	—		—		0			1
WAITE	—		0		1	—	—		—		0		1	—
PF0DDR	0	1	0	1	—	—	0	1	0	1	0	1	—	—
Pin function	PF0 input	PF0 output	PF0 input	PF0 output	$\overline{\text{WAIT}}$ input	$\overline{\text{OE}}$ * output	PF0 input	PF0 output	PF0 input	PF0 output	PF0 input	PF0 output	$\overline{\text{WAIT}}$ input	$\overline{\text{OE}}$ * output

Note: * Not supported by the H8S/2366.

9.14 Port G

Port G is a 7-bit I/O port that also has other functions. The port G has the following registers.

- Port G data direction register (PGDDR)
- Port G data register (PGDR)
- Port G register (PORTG)
- Port Function Control Register 0 (PFCR0)

9.14.1 Port G Data Direction Register (PGDDR)

The individual bits of PGDDR specify input or output for the pins of port G.

PGDDR cannot be read; if it is, an undefined value will be read.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved
6	PG6DDR	0	W	<ul style="list-style-type: none"> Modes 1, 2, 4, and 7 (when EXPE = 1) <p>Pins PG6 and PG5 function as bus control input/output pins (BREQ and BACK) when the appropriate bus controller settings are made. Otherwise, these pins are I/O ports, and their functions can be switched with PGDDR. Pin PG4 functions as the bus control input/output pin (BREQO) when the appropriate bus controller settings are made. Otherwise, when the CS7E bit is set to 1, pin PG4 functions as the $\overline{CS7}$ output pin when PG4DDR is set to 1, and as an input port when the bit is cleared to 0. When the CS7E bit is cleared to 0, pin PG4 is an I/O port, and its function can be switched with PG4DDR. When the \overline{CS} output enable bits (CS3E to CS0E) are set to 1, pins PG3 to PG0 function as \overline{CS} output pins when the corresponding PGDDR bit is set to 1, and as input ports when the bit is cleared to 0. When CS3E to CS0E are cleared to 0, pins PG3 to PG0 are I/O ports, and their functions can be switched with PGDDR.</p> <ul style="list-style-type: none"> Mode 7 (when EXPE = 0) <p>Pins PG6 to PG0 are I/O ports, and their functions can be switched with PGDDR.</p>
5	PG5DDR	0	W	
4	PG4DDR	0	W	
3	PG3DDR	0	W	
2	PG2DDR	0	W	
1	PG1DDR	0	W	
0	PG0DDR	1/0*	W	

Note: * PG0DDR is initialized to 1 in modes 1 and 2, and to 0 in modes 4 and 7.

9.14.2 Port G Data Register (PGDR)

PGDR stores output data for the port G pins.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	—	Reserved This bit is always read as 0, and cannot be modified.
6	PG6DR	0	R/W	An output data for a pin is stored when the pin function is specified to a general purpose I/O.
5	PG5DR	0	R/W	
4	PG4DR	0	R/W	
3	PG3DR	0	R/W	
2	PG2DR	0	R/W	
1	PG1DR	0	R/W	
0	PG0DR	0	R/W	

9.14.3 Port G Register (PORTG)

PORTG shows port G pin states.

PORTG cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7	—	Undefined	—	Reserved If this bit is read, it will return an undefined value.
6	PG6	—*	R	If a port G read is performed while PGDDR bits are set to 1, the PGDR values are read. If a port G read is performed while PGDDR bits are cleared to 0, the pin states are read.
5	PG5	—*	R	
4	PG4	—*	R	
3	PG3	—*	R	
2	PG2	—*	R	
1	PG1	—*	R	
0	PG0	—*	R	

Note: * Determined by the states of pins PG6 to PG0.

9.14.4 Pin Functions

Port G pins also function as the pins for bus control signal I/Os. The correspondence between the register specification and the pin functions is shown below.

- PG6/ $\overline{\text{BREQ}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit BRLE, and bit PG6DDR.

Operating mode	1, 2, 4			7				
EXPE	—			0		1		
BRLE	0		1	—		0		1
PG6DDR	0	1	—	0	1	0	1	—
Pin function	PG6 input	PG6 output	$\overline{\text{BREQ}}$ input	PG6 input	PG6 output	PG6 input	PG6 output	$\overline{\text{BREQ}}$ input

- PG5/ $\overline{\text{BACK}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit BRLE, and bit PG5DDR.

Operating mode	1, 2, 4			7				
EXPE	—			0		1		
BRLE	0		1	—		0		1
PG5DDR	0	1	—	0	1	0	1	—
Pin function	PG5 input	PG5 output	$\overline{\text{BACK}}$ output	PG5 input	PG5 output	PG5 input	PG5 output	$\overline{\text{BACK}}$ output

- PG4/ $\overline{\text{CS4}}$ / $\overline{\text{BREQO}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit BRLE, bit BREQO, bit CS4E and bit PG4DDR.

Operating mode	1, 2, 4									7										
EXPE	–									0		1								
BRLE	0				1					–		0				1				
BREQOE	–				0				1	–		–				0				1
CS4E	0		1		0		1		–	–		0		1		0		1		1
PG4DDR	0	1	0	1	0	1	0	1	–	0	1	0	1	0	1	0	1	0	1	–
Pin function	PG4 input	PG4 output	PG4 input	CS7 output	PG4 input	PG4 output	PG4 input	CS7 output	BREQO output	PG4 input	PG4 output	PG4 input	PG4 output	PG4 input	CS7 output	PG4 input	PG4 output	PG4 input	CS7 output	BREQO output

- PG3/ $\overline{\text{CS3}}$ / $\overline{\text{RAS3}}^*$, PG2/ $\overline{\text{CS2}}$ / $\overline{\text{RAS2}}^*$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit PGnDDR, bit CSnE, and bits RMTS2 to RMTS0*.

Operating mode	1, 2, 4						7						
EXPE	—						0	1					
CSnE	0		1				—	0		1			
RMTS2* to RMTS0*	—		Area n is in normal space		Area n is in DRAM* space		—	—		Area n is in normal space		Area n is in DRAM* space	
PGnDDR	0	1	0	1	—		0	1	0	1	0	1	—
Pin function	PGn input	PGn output	PGn input	$\overline{\text{CSn}}$ output	$\overline{\text{RASn}}^*$ output	PGn input	PGn output	PGn input	PGn output	PGn input	$\overline{\text{CSn}}$ output	$\overline{\text{RASn}}^*$ output	

n = 2 or 3

Note: * Not supported by the H8S/2366.

- PG1/ $\overline{\text{CS1}}$, PG0/ $\overline{\text{CS0}}$

The pin function is switched as shown below according to the operating mode, bit EXPE, bit PGnDDR, and bit CSnE.

Operating mode	1, 2, 4					7					
EXPE	—					0	1				
CSnE	0		1			—	0		1		
PGnDDR	0	1	0	1	—	0	1	0	1	0	1
Pin function	PGn input	PGn output	PGn input	$\overline{\text{CSn}}$ output	PGn input	PGn output	PGn input	PGn output	PGn input	$\overline{\text{CSn}}$ output	

n = 1 or 0

Section 10 16-Bit Timer Pulse Unit (TPU)

This LSI has an on-chip 16-bit timer pulse unit (TPU) that comprises six 16-bit timer channels. The function list of the 16-bit timer unit and its block diagram are shown in table 10.1 and figure 10.1, respectively.

10.1 Features

- Maximum 16-pulse input/output
- Selection of 8 counter input clocks for each channel
- The following operations can be set for each channel:
 - Waveform output at compare match
 - Input capture function
 - Counter clear operation
 - Synchronous operations:
 - Multiple timer counters (TCNT) can be written to simultaneously
 - Simultaneous clearing by compare match and input capture possible
 - Register simultaneous input/output possible by counter synchronous operation
- Maximum of 15-phase PWM output possible by combination with synchronous operation
- Buffer operation settable for channels 0 and 3
- Phase counting mode settable independently for each of channels 1, 2, 4, and 5
- Cascaded operation
- Fast access via internal 16-bit bus
- 26 interrupt sources
- Automatic transfer of register data
- Programmable pulse generator (PPG)* output trigger can be generated
- A/D converter conversion start trigger can be generated
- Module stop mode can be set

Note: * Not supported by the H8S/2366.

10.3 Register Descriptions

The TPU has the following registers in each channel.

- Timer control register_0 (TCR_0)
- Timer mode register_0 (TMDR_0)
- Timer I/O control register H_0 (TIORH_0)
- Timer I/O control register L_0 (TIORL_0)
- Timer interrupt enable register_0 (TIER_0)
- Timer status register_0 (TSR_0)
- Timer counter_0 (TCNT_0)
- Timer general register A_0 (TGRA_0)
- Timer general register B_0 (TGRB_0)
- Timer general register C_0 (TGRC_0)
- Timer general register D_0 (TGRD_0)
- Timer control register_1 (TCR_1)
- Timer mode register_1 (TMDR_1)
- Timer I/O control register_1 (TIOR_1)
- Timer interrupt enable register_1 (TIER_1)
- Timer status register_1 (TSR_1)
- Timer counter_1 (TCNT_1)
- Timer general register A_1 (TGRA_1)
- Timer general register B_1 (TGRB_1)
- Timer control register_2 (TCR_2)
- Timer mode register_2 (TMDR_2)
- Timer I/O control register_2 (TIOR_2)
- Timer interrupt enable register_2 (TIER_2)
- Timer status register_2 (TSR_2)
- Timer counter_2 (TCNT_2)
- Timer general register A_2 (TGRA_2)
- Timer general register B_2 (TGRB_2)
- Timer control register_3 (TCR_3)
- Timer mode register_3 (TMDR_3)
- Timer I/O control register H_3 (TIORH_3)
- Timer I/O control register L_3 (TIORL_3)
- Timer interrupt enable register_3 (TIER_3)
- Timer status register_3 (TSR_3)
- Timer counter_3 (TCNT_3)

- Timer general register A_3 (TGRA_3)
- Timer general register B_3 (TGRB_3)

- Timer mode register_4 (TMDR_4)
- Timer I/O control register_4 (TIOR_4)
- Timer interrupt enable register_4 (TIER_4)
- Timer status register_4 (TSR_4)
- Timer counter_4 (TCNT_4)
- Timer general register A_4 (TGRA_4)
- Timer general register B_4 (TGRB_4)
- Timer control register_5 (TCR_5)
- Timer mode register_5 (TMDR_5)
- Timer I/O control register_5 (TIOR_5)
- Timer interrupt enable register_5 (TIER_5)
- Timer status register_5 (TSR_5)
- Timer counter_5 (TCNT_5)
- Timer general register A_5 (TGRA_5)
- Timer general register B_5 (TGRB_5)

Common Registers

- Timer start register (TSTR)
- Timer synchronous register (TSYR)

10.3.1 Timer Control Register (TCR)

The TCR registers control the TCNT operation for each channel. The TPU has a total of six TCR registers, one for each channel. TCR register settings should be made only when TCNT operation is stopped.

Bit	Bit Name	Initial Value	R/W	Description
7	CCLR2	0	R/W	Counter Clear 2 to 0
6	CCLR1	0	R/W	These bits select the TCNT counter clearing source. See tables 10.3 and 10.4 for details.
5	CCLR0	0	R/W	
4	CKEG1	0	R/W	Clock Edge 1 and 0
3	CKEG0	0	R/W	These bits select the input clock edge. When the input clock is counted using both edges, the input clock period is halved (e.g. $\phi/4$ both edges = $\phi/2$ rising edge). If phase counting mode is used on channels 1, 2, 4, and 5, this setting is ignored and the phase counting mode setting has priority. Internal clock edge selection is valid when the input clock is $\phi/4$ or slower. This setting is ignored if the input clock is $\phi/1$, or when overflow/underflow of another channel is selected. 00: Count at rising edge 01: Count at falling edge 1x: Count at both edges Legend: x: Don't care
2	TPSC2	0	R/W	Time Prescaler 2 to 0
1	TPSC1	0	R/W	These bits select the TCNT counter clock. The clock source can be selected independently for each channel. See tables 10.5 to 10.10 for details.
0	TPSC0	0	R/W	

Table 10.3 CCLR2 to CCLR0 (Channels 0 and 3)

Channel	Bit 7 CCLR2	Bit 6 CCLR1	Bit 5 CCLR0	Description
0, 3	0	0	0	TCNT clearing disabled
			1	TCNT cleared by TGRA compare match/input capture
		1	0	TCNT cleared by TGRB compare match/input capture
			1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* ¹
	1	0	0	TCNT clearing disabled
			1	TCNT cleared by TGRC compare match/input capture* ²
		1	0	TCNT cleared by TGRD compare match/input capture* ²
			1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* ¹

Notes: *1 Synchronous operation setting is performed by setting the SYNC bit in TSYR to 1.

*2 When TGRC or TGRD is used as a buffer register, TCNT is not cleared because the buffer register setting has priority, and compare match/input capture does not occur.

Table 10.4 CCLR2 to CCLR0 (Channels 1, 2, 4, and 5)

Channel	Bit 7 Reserved* ²	Bit 6 CCLR1	Bit 5 CCLR0	Description
1, 2, 4, 5	0	0	0	TCNT clearing disabled
			1	TCNT cleared by TGRA compare match/input capture
		1	0	TCNT cleared by TGRB compare match/input capture
			1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* ¹

Notes: *1 Synchronous operation setting is performed by setting the SYNC bit in TSYR to 1.

*2 Bit 7 is reserved in channels 1, 2, 4, and 5. It is always read as 0 and cannot be modified.

Table 10.5 TPSC2 to TPSC0 (Channel 0)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
0	0	0	0	Internal clock: counts on $\phi/1$
			1	Internal clock: counts on $\phi/4$
		1	0	Internal clock: counts on $\phi/16$
			1	Internal clock: counts on $\phi/64$
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input
		1	0	External clock: counts on TCLKC pin input
			1	External clock: counts on TCLKD pin input

Table 10.6 TPSC2 to TPSC0 (Channel 1)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
1	0	0	0	Internal clock: counts on $\phi/1$
			1	Internal clock: counts on $\phi/4$
		1	0	Internal clock: counts on $\phi/16$
			1	Internal clock: counts on $\phi/64$
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input
		1	0	Internal clock: counts on $\phi/256$
			1	Counts on TCNT2 overflow/underflow

Note: This setting is ignored when channel 1 is in phase counting mode.

Table 10.7 TPSC2 to TPSC0 (Channel 2)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
2	0	0	0	Internal clock: counts on $\phi/1$
			1	Internal clock: counts on $\phi/4$
		1	0	Internal clock: counts on $\phi/16$
			1	Internal clock: counts on $\phi/64$
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input
		1	0	External clock: counts on TCLKC pin input
			1	Internal clock: counts on $\phi/1024$

Note: This setting is ignored when channel 2 is in phase counting mode.

Table 10.8 TPSC2 to TPSC0 (Channel 3)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
3	0	0	0	Internal clock: counts on $\phi/1$
			1	Internal clock: counts on $\phi/4$
		1	0	Internal clock: counts on $\phi/16$
			1	Internal clock: counts on $\phi/64$
	1	0	0	External clock: counts on TCLKA pin input
			1	Internal clock: counts on $\phi/1024$
		1	0	Internal clock: counts on $\phi/256$
			1	Internal clock: counts on $\phi/4096$

Table 10.9 TPSC2 to TPSC0 (Channel 4)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
4	0	0	0	Internal clock: counts on $\phi/1$
			1	Internal clock: counts on $\phi/4$
		1	0	Internal clock: counts on $\phi/16$
			1	Internal clock: counts on $\phi/64$
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKC pin input
		1	0	Internal clock: counts on $\phi/1024$
			1	Counts on TCNT5 overflow/underflow

Note: This setting is ignored when channel 4 is in phase counting mode.

Table 10.10 TPSC2 to TPSC0 (Channel 5)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
5	0	0	0	Internal clock: counts on $\phi/1$
			1	Internal clock: counts on $\phi/4$
		1	0	Internal clock: counts on $\phi/16$
			1	Internal clock: counts on $\phi/64$
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKC pin input
		1	0	Internal clock: counts on $\phi/256$
			1	External clock: counts on TCLKD pin input

Note: This setting is ignored when channel 5 is in phase counting mode.

10.3.2 Timer Mode Register (TMDR)

TMDR registers are used to set the operating mode for each channel. The TPU has six TMDR registers, one for each channel. TMDR register settings should be made only when TCNT operation is stopped.

Bit	Bit Name	Initial Value	R/W	Description
7	—	1	—	Reserved
6	—	1	—	These bits are always read as 1 and cannot be modified.
5	BFB	0	R/W	Buffer Operation B Specifies whether TGRB is to operate in the normal way, or TGRB and TGRD are to be used together for buffer operation. When TGRD is used as a buffer register, TGRD input capture/output compare is not generated. In channels 1, 2, 4, and 5, which have no TGRD, bit 5 is reserved. It is always read as 0 and cannot be modified. 0: TGRB operates normally 1: TGRB and TGRD used together for buffer operation
4	BFA	0	R/W	Buffer Operation A Specifies whether TGRA is to operate in the normal way, or TGRA and TGRC are to be used together for buffer operation. When TGRC is used as a buffer register, TGRC input capture/output compare is not generated. In channels 1, 2, 4, and 5, which have no TGRC, bit 4 is reserved. It is always read as 0 and cannot be modified. 0: TGRA operates normally 1: TGRA and TGRC used together for buffer operation
3	MD3	0	R/W	Modes 3 to 0
2	MD2	0	R/W	These bits are used to set the timer operating mode. MD3 is a reserved bit. The write value should always be 0. See table 10.11 for details.
1	MD1	0	R/W	
0	MD0	0	R/W	

Table 10.11 MD3 to MD0

Bit 3 MD3* ¹	Bit 2 MD2* ²	Bit 1 MD1	Bit 0 MD0	Description
0	0	0	0	Normal operation
			1	Reserved
		1	0	PWM mode 1
			1	PWM mode 2
	1	0	0	Phase counting mode 1
			1	Phase counting mode 2
		1	0	Phase counting mode 3
			1	Phase counting mode 4
1	x	x	x	—

Legend: x: Don't care

Notes: *1 MD3 is a reserved bit. The write value should always be 0.

*2 Phase counting mode cannot be set for channels 0 and 3. In this case, 0 should always be written to MD2.

10.3.3 Timer I/O Control Register (TIOR)

TIOR registers control the TGR registers. The TPU has eight TIOR registers, two each for channels 0 and 3, and one each for channels 1, 2, 4, and 5. Care is required since TIOR is affected by the TMDR setting.

The initial output specified by TIOR is valid when the counter is stopped (the CST bit in TSTR is cleared to 0). Note also that, in PWM mode 2, the output at the point at which the counter is cleared to 0 is specified.

When TGRC or TGRD is designated for buffer operation, this setting is invalid and the register operates as a buffer register.

TIORH_0, TIOR_1, TIOR_2, TIORH_3, TIOR_4, TIOR_5

Bit	Bit Name	Initial Value	R/W	Description
7	IOB3	0	R/W	I/O Control B3 to B0
6	IOB2	0	R/W	Specify the function of TGRB. For details, see tables 10.12, 10.14, 10.15, 10.16, 10.18, and 10.19.
5	IOB1	0	R/W	
4	IOB0	0	R/W	
3	IOA3	0	R/W	I/O Control A3 to A0
2	IOA2	0	R/W	Specify the function of TGRA. For details, see tables 10.20, 10.22, 10.23, 10.24, 10.26, and 10.27.
1	IOA1	0	R/W	
0	IOA0	0	R/W	

TIORL_0, TIORL_3

Bit	Bit Name	Initial Value	R/W	Description
7	IOD3	0	R/W	I/O Control D3 to D0
6	IOD2	0	R/W	Specify the function of TGRD. For details, see tables 10.13, and 10.17.
5	IOD1	0	R/W	
4	IOD0	0	R/W	
3	IOC3	0	R/W	I/O Control C3 to C0
2	IOC2	0	R/W	Specify the function of TGRC. For details, see tables 10.21, and 10.25
1	IOC1	0	R/W	
0	IOC0	0	R/W	

Table 10.12 TIORH_0

				Description	
Bit 7 IOB3	Bit 6 IOB2	Bit 5 IOB1	Bit 4 IOB0	TGRB_0 Function	TIOCB0 Pin Function
0	0	0	0	Output	Output disabled

10.3.4 Timer Interrupt Enable Register (TIER)

TIER registers control enabling or disabling of interrupt requests for each channel. The TPU has six TIER registers, one for each channel.

Bit	Bit Name	Initial value	R/W	Description
7	TTGE	0	R/W	A/D Conversion Start Request Enable Enables or disables generation of A/D conversion start requests by TGRA input capture/compare match. 0: A/D conversion start request request generation disabled 1: A/D conversion start request generation enabled
6	—	1	—	Reserved This bit is always read as 1 and cannot be modified.
5	TCIEU	0	R/W	Underflow Interrupt Enable Enables or disables interrupt requests (TCIU) by the TCFU flag when the TCFU flag in TSR is set to 1 in channels 1, 2, 4, and 5. In channels 0 and 3, bit 5 is reserved. It is always read as 0 and cannot be modified. 0: Interrupt requests (TCIU) by TCFU disabled 1: Interrupt requests (TCIU) by TCFU enabled
4	TCIEV	0	R/W	Overflow Interrupt Enable Enables or disables interrupt requests (TCIV) by the TCFV flag when the TCFV flag in TSR is set to 1. 0: Interrupt requests (TCIV) by TCFV disabled 1: Interrupt requests (TCIV) by TCFV enabled
3	TGIED	0	R/W	TGR Interrupt Enable D Enables or disables interrupt requests (TGID) by the TGFD bit when the TGFD bit in TSR is set to 1 in channels 0 and 3. In channels 1, 2, 4, and 5, bit 3 is reserved. It is always read as 0 and cannot be modified. 0: Interrupt requests (TGID) by TGFD bit disabled 1: Interrupt requests (TGID) by TGFD bit enabled

Bit	Bit Name	Initial value	R/W	Description
2	TGIEC	0	R/W	<p>TGR Interrupt Enable C</p> <p>Enables or disables interrupt requests (TGIC) by the TGFC bit when the TGFC bit in TSR is set to 1 in channels 0 and 3.</p> <p>In channels 1, 2, 4, and 5, bit 2 is reserved. It is always read as 0 and cannot be modified.</p> <p>0: Interrupt requests (TGIC) by TGFC bit disabled</p> <p>1: Interrupt requests (TGIC) by TGFC bit enabled</p>
1	TGIEB	0	R/W	<p>TGR Interrupt Enable B</p> <p>Enables or disables interrupt requests (TGIB) by the TGFB bit when the TGFB bit in TSR is set to 1.</p> <p>0: Interrupt requests (TGIB) by TGFB bit disabled</p> <p>1: Interrupt requests (TGIB) by TGFB bit enabled</p>
0	TGIEA	0	R/W	<p>TGR Interrupt Enable A</p> <p>Enables or disables interrupt requests (TGIA) by the TGFA bit when the TGFA bit in TSR is set to 1.</p> <p>0: Interrupt requests (TGIA) by TGFA bit disabled</p> <p>1: Interrupt requests (TGIA) by TGFA bit enabled</p>

10.3.5 Timer Status Register (TSR)

TSR registers indicate the status of each channel. The TPU has six TSR registers, one for each channel.

Bit	Bit Name	Initial value	R/W	Description
7	TCFD	1	R	Count Direction Flag Status flag that shows the direction in which TCNT counts in channels 1, 2, 4, and 5. In channels 0 and 3, bit 7 is reserved. It is always read as 1 and cannot be modified. 0: TCNT counts down 1: TCNT counts up
6	—	1	—	Reserved This bit is always read as 1 and cannot be modified.
5	TCFU	0	R/(W)* ¹	Underflow Flag Status flag that indicates that TCNT underflow has occurred when channels 1, 2, 4, and 5 are set to phase counting mode. In channels 0 and 3, bit 5 is reserved. It is always read as 0 and cannot be modified. [Setting condition] When the TCNT value underflows (changes from H'0000 to H'FFFF) [Clearing condition] When 0 is written to TCFU after reading TCFU = 1
4	TCFV	0	R/(W)* ¹	Overflow Flag Status flag that indicates that TCNT overflow has occurred. [Setting condition] When the TCNT value overflows (changes from H'FFFF to H'0000) [Clearing condition] When 0 is written to TCFV after reading TCFV = 1

Bit	Bit Name	Initial value	R/W	Description
3	TGFD	0	R/(W)* ¹	<p>Input Capture/Output Compare Flag D</p> <p>Status flag that indicates the occurrence of TGRD input capture or compare match in channels 0 and 3. In channels 1, 2, 4, and 5, bit 3 is reserved. It is always read as 0 and cannot be modified.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When TCNT = TGRD while TGRD is functioning as output compare register When TCNT value is transferred to TGRD by input capture signal while TGRD is functioning as input capture register <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When DTC is activated by TGID interrupt while DISEL bit of MRB in DTC is 0 When 0 is written to TGFD after reading TGFD = 1
2	TGFC	0	R/(W)* ¹	<p>Input Capture/Output Compare Flag C</p> <p>Status flag that indicates the occurrence of TGRC input capture or compare match in channels 0 and 3. In channels 1, 2, 4, and 5, bit 2 is reserved. It is always read as 0 and cannot be modified.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When TCNT = TGRC while TGRC is functioning as output compare register When TCNT value is transferred to TGRC by input capture signal while TGRC is functioning as input capture register <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When DTC is activated by TGIC interrupt while DISEL bit of MRB in DTC is 0 When 0 is written to TGFC after reading TGFC = 1

Bit	Bit Name	Initial value	R/W	Description
1	TGFB	0	R/(W)* ¹	<p>Input Capture/Output Compare Flag B</p> <p>Status flag that indicates the occurrence of TGRB input capture or compare match.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When TCNT = TGRB while TGRB is functioning as output compare register When TCNT value is transferred to TGRB by input capture signal while TGRB is functioning as input capture register <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When DTC is activated by TGIB interrupt while DISEL bit of MRB in DTC is 0 When 0 is written to TGFB after reading TGFB = 1
0	TGFA	0	R/(W)* ¹	<p>Input Capture/Output Compare Flag A</p> <p>Status flag that indicates the occurrence of TGRA input capture or compare match.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When TCNT = TGRA while TGRA is functioning as output compare register When TCNT value is transferred to TGRA by input capture signal while TGRA is functioning as input capture register <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When DTC is activated by TGIA interrupt while DISEL bit of MRB in DTC is 0 When 0 is written to TGFA after reading TGFA = 1 When DMAC is activated by TGIA interrupt while DTE bit of DMABCR in DMAC is set to 1*²

Notes: *1 Only 0 can be written, for flag clearing.

*2 Not supported by the H8S/2366.

10.3.6 Timer Counter (TCNT)

The TCNT registers are 16-bit readable/writable counters. The TPU has six TCNT counters, one for each channel.

The TCNT counters are initialized to H'0000 by a reset, or in hardware standby mode.

The TCNT counters cannot be accessed in 8-bit units; they must always be accessed as a 16-bit unit.

10.3.7 Timer General Register (TGR)

The TGR registers are 16-bit readable/writable registers with a dual function as output compare and input capture registers. The TPU has 16 TGR registers, four each for channels 0 and 3 and two each for channels 1, 2, 4, and 5. TGRC and TGRD for channels 0 and 3 can also be designated for operation as buffer registers. The TGR registers cannot be accessed in 8-bit units; they must always be accessed as a 16-bit unit. TGR buffer register combinations are TGRA–TGRC and TGRB–TGRD.

10.3.8 Timer Start Register (TSTR)

TSTR selects operation/stoppage for channels 0 to 5. When setting the operating mode in TMDR or setting the count clock in TCR, first stop the TCNT counter.

Bit	Bit Name	Initial value	R/W	Description
7	—	0	—	Reserved
6	—	0	—	The write value should always be 0.
5	CST5	0	R/W	Counter Start 5 to 0
4	CST4	0	R/W	These bits select operation or stoppage for TCNT. If 0 is written to the CST bit during operation with the TIOC pin designated for output, the counter stops but the TIOC pin output compare output level is retained. If TIOR is written to when the CST bit is cleared to 0, the pin output level will be changed to the set initial output value. 0: TCNT_5 to TCNT_0 count operation is stopped 1: TCNT_5 to TCNT_0 performs count operation
3	CST3	0	R/W	
2	CST2	0	R/W	
1	CST1	0	R/W	
0	CST0	0	R/W	

10.3.9 Timer Synchronous Register (TSYR)

TSYR selects independent operation or synchronous operation for the TCNT counters of channels 0 to 5. A channel performs synchronous operation when the corresponding bit in TSYR is set to 1.

Bit	Bit Name	Initial value	R/W	Description
7	—	—	R/W	Reserved
6	—	—	R/W	The write value should always be 0.
5	SYNC5	0	R/W	Timer Synchronization 5 to 0
4	SYNC4	0	R/W	These bits select whether operation is independent of or synchronized with other channels.
3	SYNC3	0	R/W	
2	SYNC2	0	R/W	When synchronous operation is selected, synchronous presetting of multiple channels, and synchronous clearing through counter clearing on another channel are possible. To set synchronous operation, the SYNC bits for at least two channels must be set to 1. To set synchronous clearing, in addition to the SYNC bit, the TCNT clearing source must also be set by means of bits CCLR2 to CCLR0 in TCR. 0: TCNT_5 to TCNT_0 operates independently (TCNT presetting /clearing is unrelated to other channels) 1: TCNT_5 to TCNT_0 performs synchronous operation (TCNT synchronous presetting/ synchronous clearing is possible)
1	SYNC1	0	R/W	
0	SYNC0	0	R/W	

10.4 Operation

10.4.1 Basic Functions

Each channel has a TCNT and TGR register. TCNT performs up-counting, and is also capable of free-running operation, periodic counting, and external event counting.

Each TGR can be used as an input capture register or output compare register.

Counter Operation: When one of bits CST0 to CST5 is set to 1 in TSTR, the TCNT counter for the corresponding channel starts counting. TCNT can operate as a free-running counter, periodic counter, and so on.

1. Example of count operation setting procedure

Figure 10.2 shows an example of the count operation setting procedure.

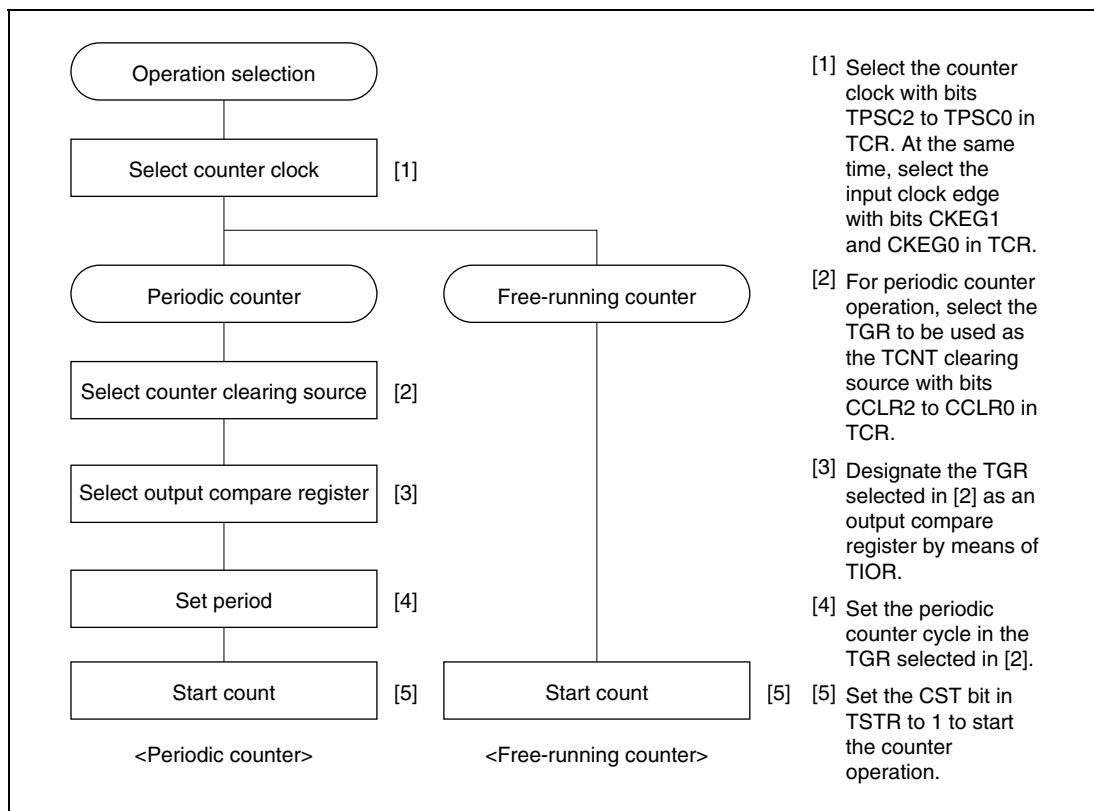

Figure 10.2 Example of Counter Operation Setting Procedure

2. Free-running count operation and periodic count operation

Immediately after a reset, the TPU's TCNT counters are all designated as free-running counters. When the relevant bit in TSTR is set to 1 the corresponding TCNT counter starts up-count operation as a free-running counter. When TCNT overflows (changes from H'FFFF to H'0000), the TCFV bit in TSR is set to 1. If the value of the corresponding TCIEV bit in TIER is 1 at this point, the TPU requests an interrupt. After overflow, TCNT starts counting up again from H'0000.

Figure 10.3 illustrates free-running counter operation.

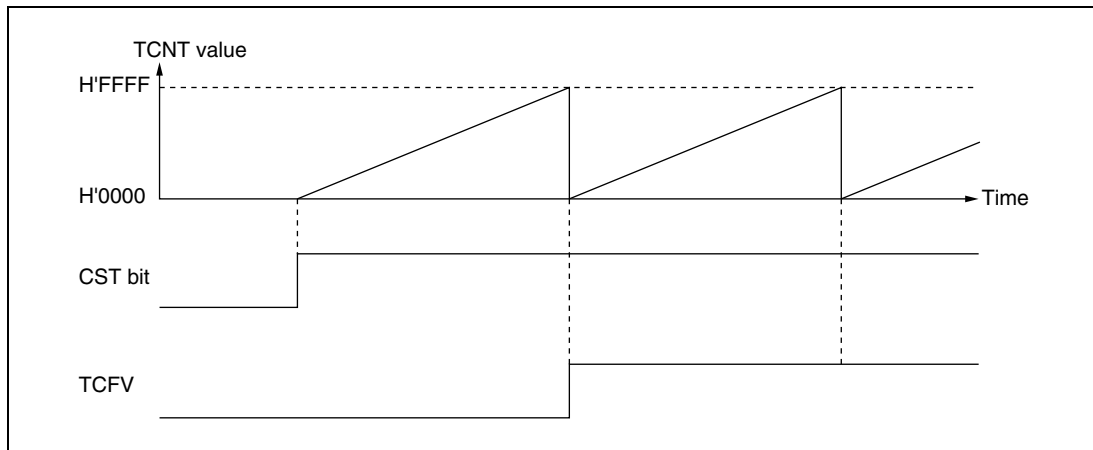

Figure 10.3 Free-Running Counter Operation

When compare match is selected as the TCNT clearing source, the TCNT counter for the relevant channel performs periodic count operation. The TGR register for setting the period is designated as an output compare register, and counter clearing by compare match is selected by means of bits CCLR2 to CCLR0 in TCR. After the settings have been made, TCNT starts count-up operation as a periodic counter when the corresponding bit in TSTR is set to 1. When the count value matches the value in TGR, the TGF bit in TSR is set to 1 and TCNT is cleared to H'0000.

If the value of the corresponding TGIE bit in TIER is 1 at this point, the TPU requests an interrupt. After a compare match, TCNT starts counting up again from H'0000.

Figure 10.4 illustrates periodic counter operation.

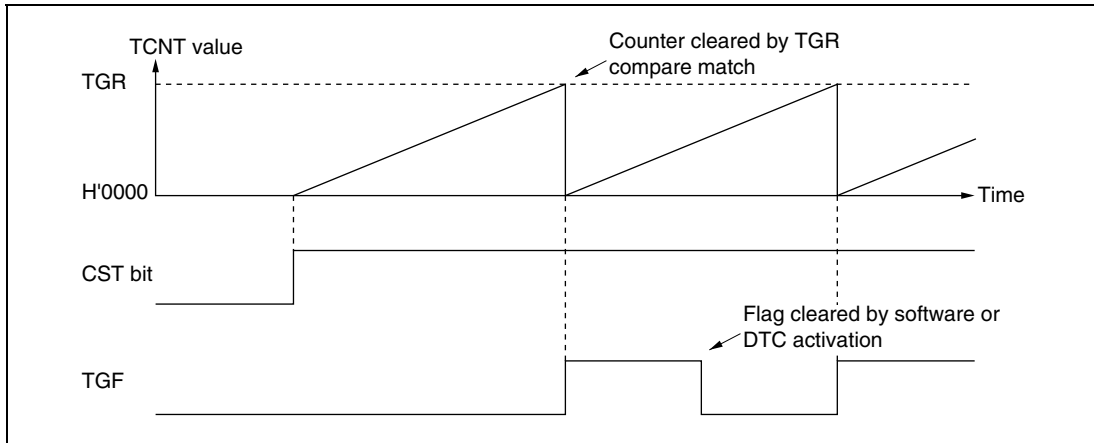

Figure 10.4 Periodic Counter Operation

Waveform Output by Compare Match: The TPU can perform 0, 1, or toggle output from the corresponding output pin using a compare match.

1. Example of setting procedure for waveform output by compare match

Figure 10.5 shows an example of the setting procedure for waveform output by a compare match.

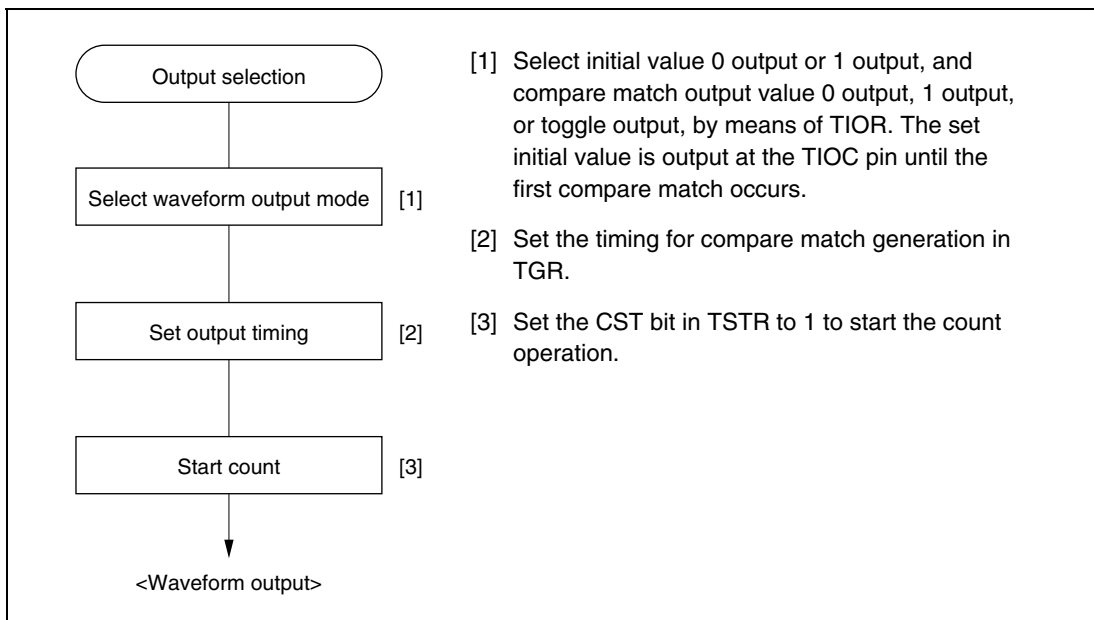

Figure 10.5 Example of Setting Procedure for Waveform Output by Compare Match

2. Examples of waveform output operation

Figure 10.6 shows an example of 0 output/1 output.

In this example, TCNT has been designated as a free-running counter, and settings have been made so that 1 is output by compare match A, and 0 is output by compare match B. When the set level and the pin level match, the pin level does not change.

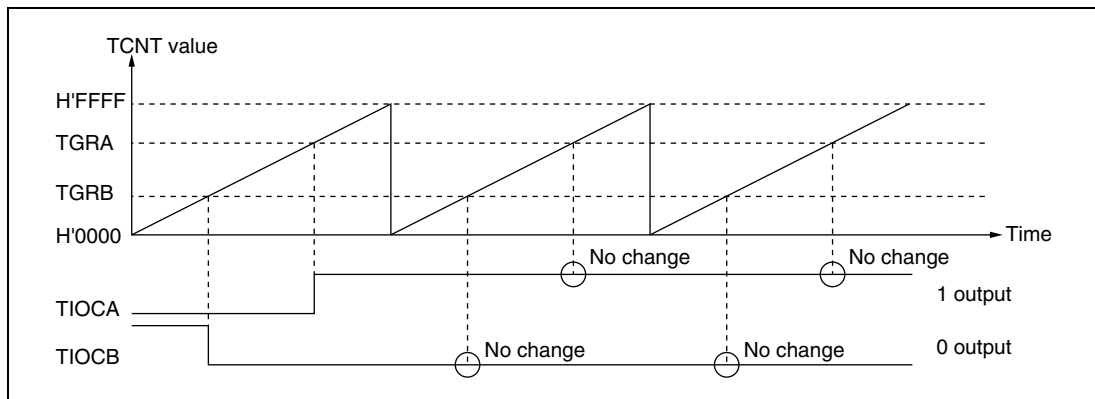

Figure 10.6 Example of 0 Output/1 Output Operation

Figure 10.7 shows an example of toggle output.

In this example TCNT has been designated as a periodic counter (with counter clearing performed by compare match B), and settings have been made so that output is toggled by both compare match A and compare match B.

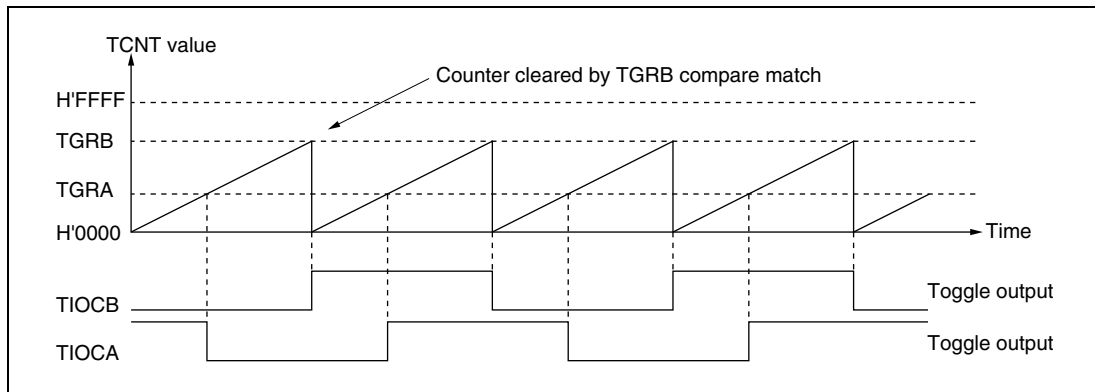

Figure 10.7 Example of Toggle Output Operation

Input Capture Function: The TCNT value can be transferred to TGR on detection of the TIOC pin input edge.

Rising edge, falling edge, or both edges can be selected as the detection edge. For channels 0, 1, 3, and 4, it is also possible to specify another channel's counter input clock or compare match signal as the input capture source.

Note: When another channel's counter input clock is used as the input capture input for channels 0 and 3, $\phi/1$ should not be selected as the counter input clock used for input capture input. Input capture will not be generated if $\phi/1$ is selected.

1. Example of setting procedure for input capture operation

Figure 10.8 shows an example of the setting procedure for input capture operation.

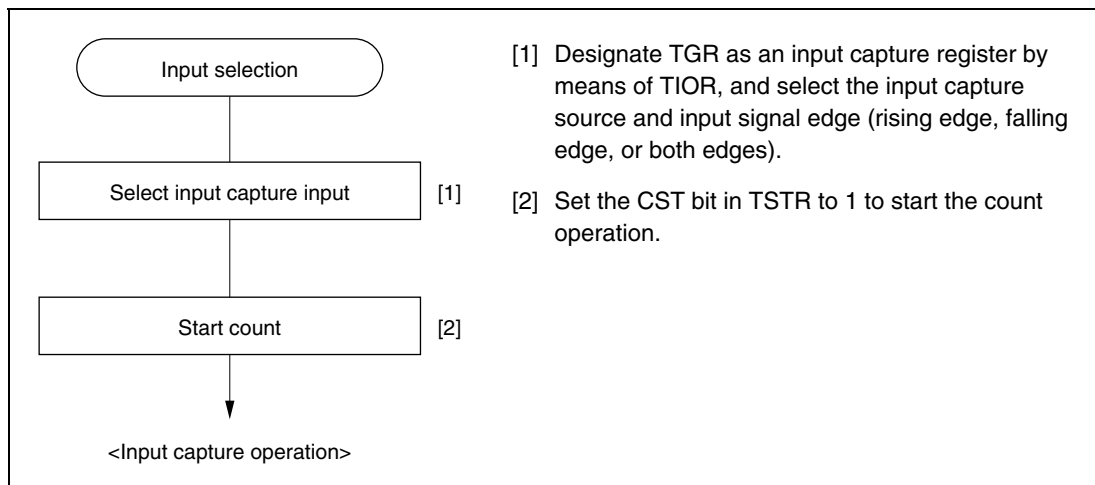

Figure 10.8 Example of Setting Procedure for Input Capture Operation

2. Example of input capture operation

Figure 10.9 shows an example of input capture operation.

In this example both rising and falling edges have been selected as the TIOCA pin input capture input edge, falling edge has been selected as the TIOCB pin input capture input edge, and counter clearing by TGRB input capture has been designated for TCNT.

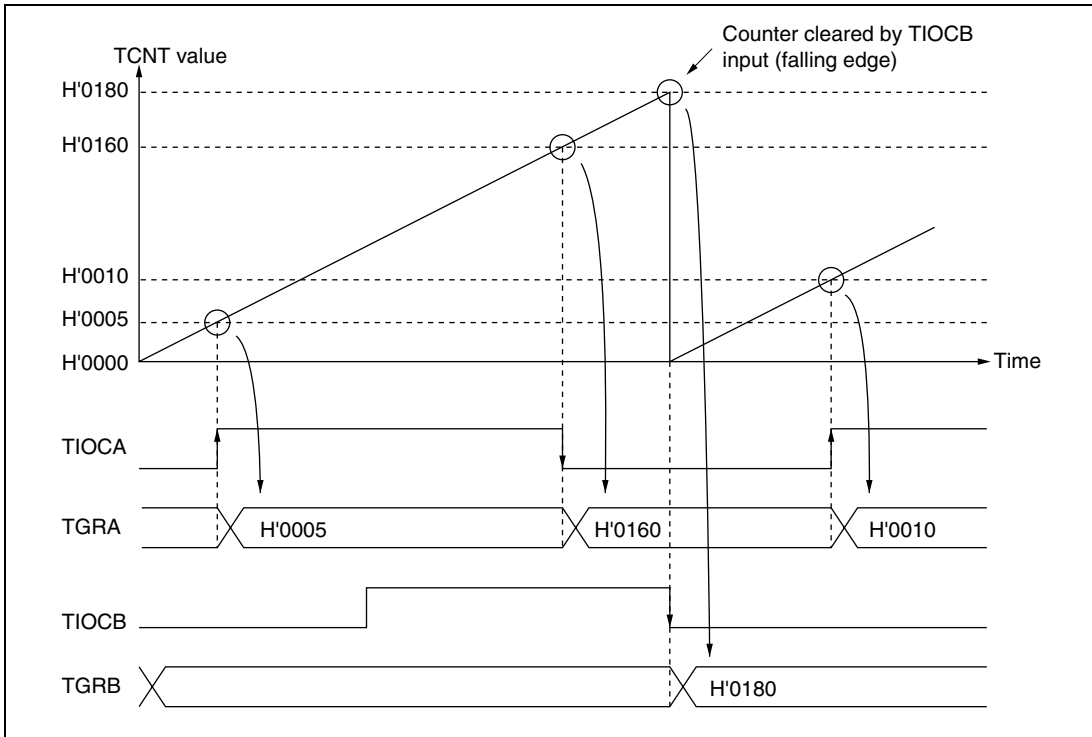

Figure 10.9 Example of Input Capture Operation

10.4.2 Synchronous Operation

In synchronous operation, the values in multiple TCNT counters can be rewritten simultaneously (synchronous presetting). Also, multiple of TCNT counters can be cleared simultaneously (synchronous clearing) by making the appropriate setting in TCR.

Synchronous operation enables TGR to be incremented with respect to a single time base.

Channels 0 to 5 can all be designated for synchronous operation.

Example of Synchronous Operation Setting Procedure: Figure 10.10 shows an example of the synchronous operation setting procedure.

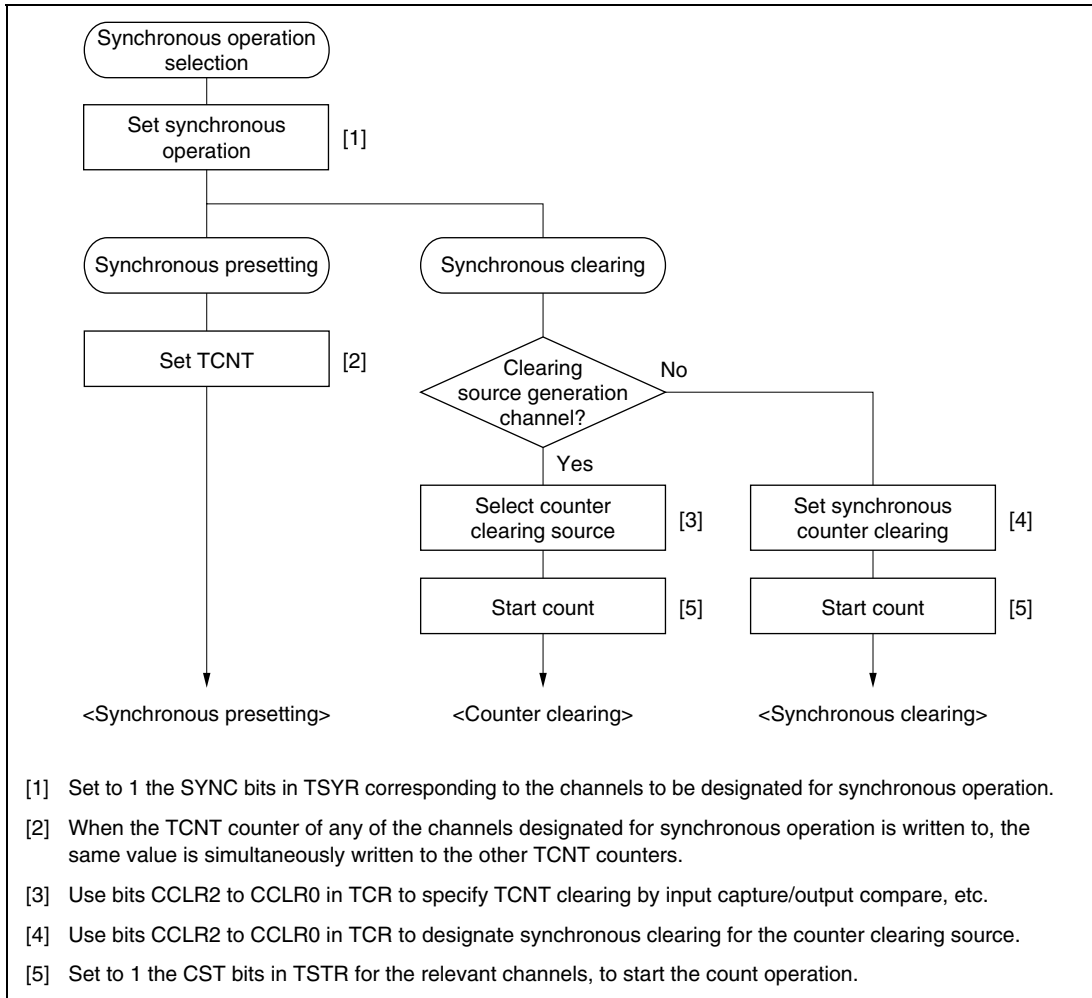

Figure 10.10 Example of Synchronous Operation Setting Procedure

Example of Synchronous Operation: Figure 10.11 shows an example of synchronous operation.

In this example, synchronous operation and PWM mode 1 have been designated for channels 0 to 2, TGRB_0 compare match has been set as the channel 0 counter clearing source, and synchronous clearing has been set for the channel 1 and 2 counter clearing source.

Three-phase PWM waveforms are output from pins TIOCA0, TIOCA1, and TIOCA2. At this time, synchronous presetting, and synchronous clearing by TGRB_0 compare match, is performed for channel 0 to 2 TCNT counters, and the data set in TGRB_0 is used as the PWM cycle.

For details on PWM modes, see section 10.4.5, PWM Modes.

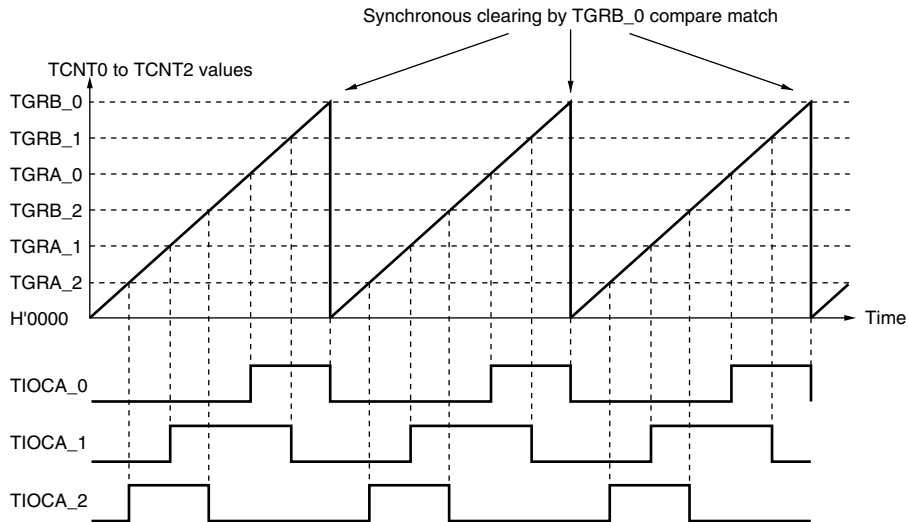

Figure 10.11 Example of Synchronous Operation

10.4.3 Buffer Operation

Buffer operation, provided for channels 0 and 3, enables TGRC and TGRD to be used as buffer registers.

Buffer operation differs depending on whether TGR has been designated as an input capture register or a compare match register.

Table 10.28 shows the register combinations used in buffer operation.

Table 10.28 Register Combinations in Buffer Operation

Channel	Timer General Register	Buffer Register
0	TGRA_0	TGRC_0
	TGRB_0	TGRD_0
3	TGRA_3	TGRC_3
	TGRB_3	TGRD_3

- When TGR is an output compare register

When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register.

This operation is illustrated in figure 10.12.

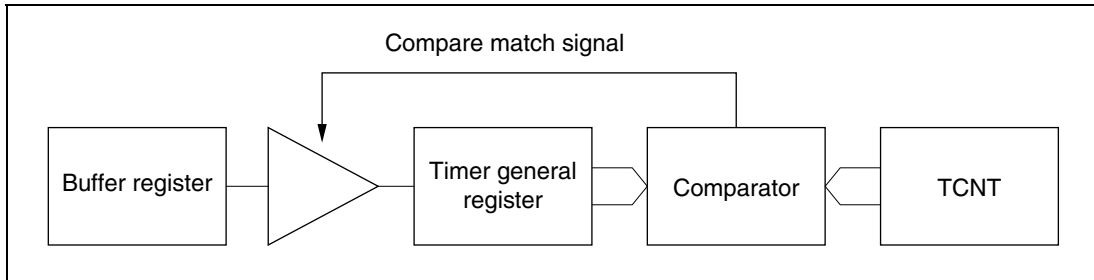

Figure 10.12 Compare Match Buffer Operation

- When TGR is an input capture register

When input capture occurs, the value in TCNT is transferred to TGR and the value previously held in the timer general register is transferred to the buffer register.

This operation is illustrated in figure 10.13.

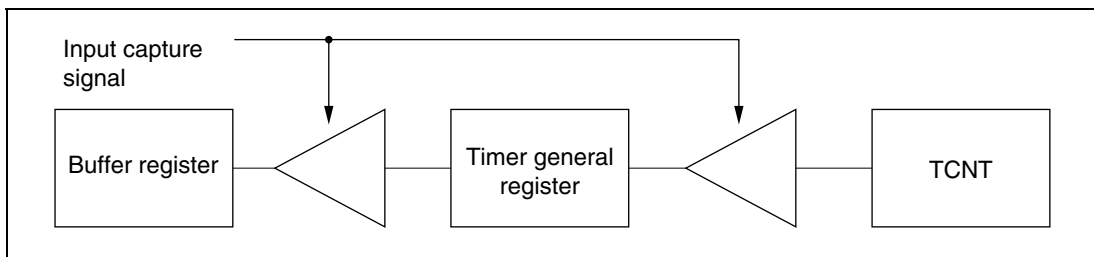

Figure 10.13 Input Capture Buffer Operation

Example of Buffer Operation Setting Procedure: Figure 10.14 shows an example of the buffer operation setting procedure.

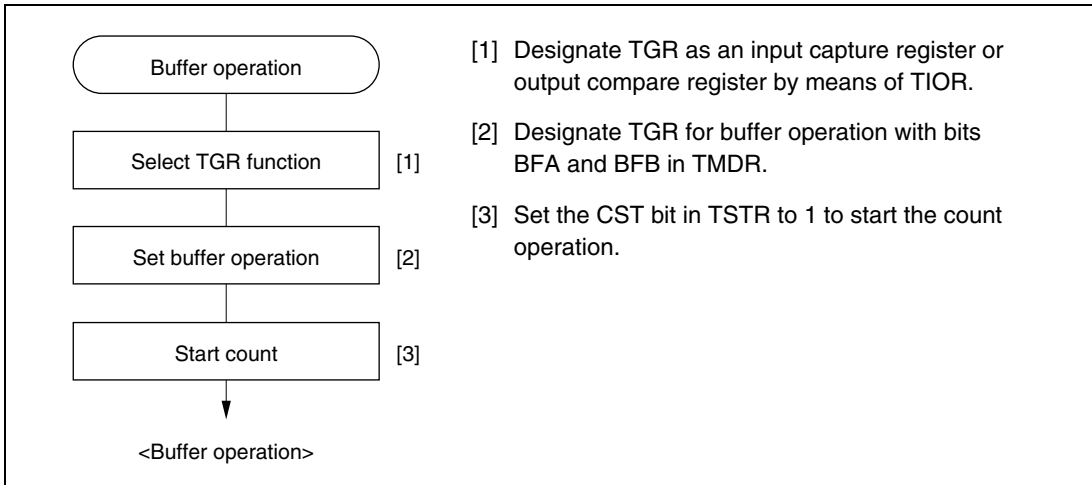

Figure 10.14 Example of Buffer Operation Setting Procedure

Examples of Buffer Operation:

1. When TGR is an output compare register

Figure 10.15 shows an operation example in which PWM mode 1 has been designated for channel 0, and buffer operation has been designated for TGRA and TGRC. The settings used in this example are TCNT clearing by compare match B, 1 output at compare match A, and 0 output at compare match B.

As buffer operation has been set, when compare match A occurs the output changes and the value in buffer register TGRC is simultaneously transferred to timer general register TGRA. This operation is repeated each time compare match A occurs.

For details on PWM modes, see section 10.4.5, PWM Modes.

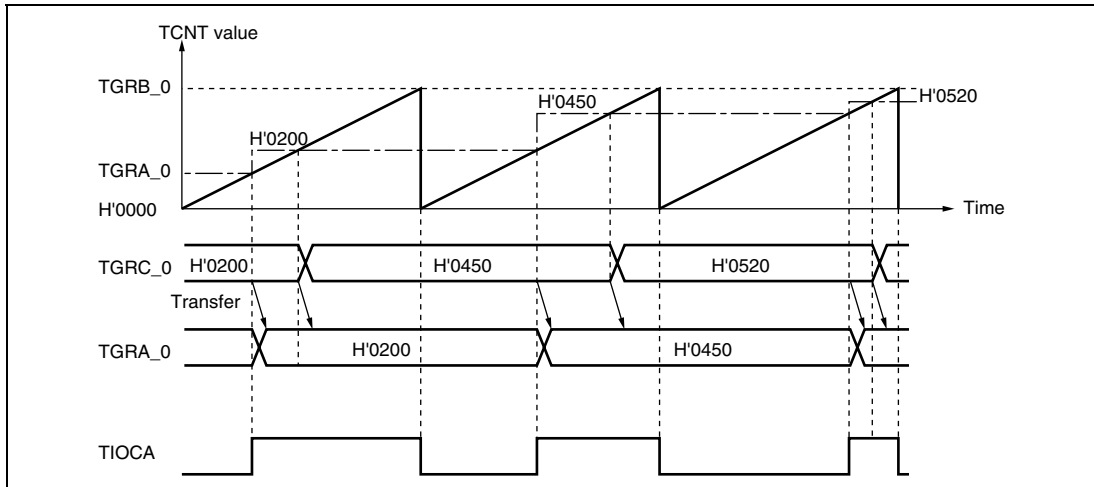

Figure 10.15 Example of Buffer Operation (1)

2. When TGR is an input capture register

Figure 10.16 shows an operation example in which TGRA has been designated as an input capture register, and buffer operation has been designated for TGRA and TGRC.

Counter clearing by TGRA input capture has been set for TCNT, and both rising and falling edges have been selected as the TIOCA pin input capture input edge.

As buffer operation has been set, when the TCNT value is stored in TGRA upon occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

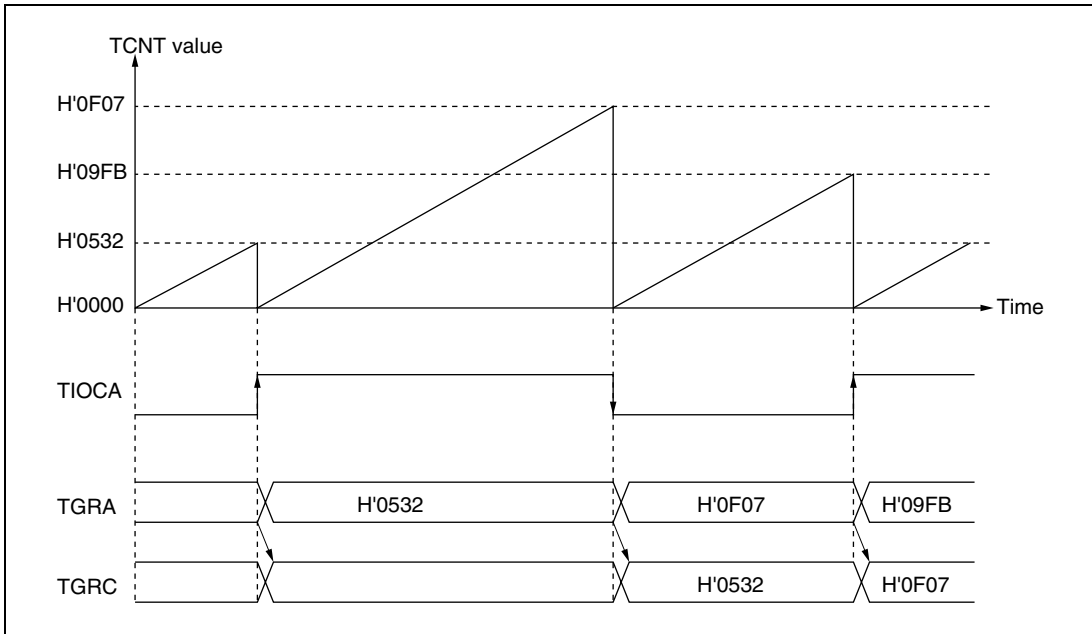

Figure 10.16 Example of Buffer Operation (2)

10.4.4 Cascaded Operation

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter.

This function works by counting the channel 1 (channel 4) counter clock at overflow/underflow of TCNT_2 (TCNT_5) as set in bits TPSC2 to TPSC0 in TCR.

Underflow occurs only when the lower 16-bit TCNT is in phase counting mode.

Table 10.29 shows the register combinations used in cascaded operation.

Note: When phase counting mode is set for channel 1 or 4, the counter clock setting is invalid and the counter operates independently in phase counting mode.

Table 10.29 Cascaded Combinations

Combination	Upper 16 Bits	Lower 16 Bits
Channels 1 and 2	TCNT_1	TCNT_2
Channels 4 and 5	TCNT_4	TCNT_5

Example of Cascaded Operation Setting Procedure: Figure 10.17 shows an example of the setting procedure for cascaded operation.

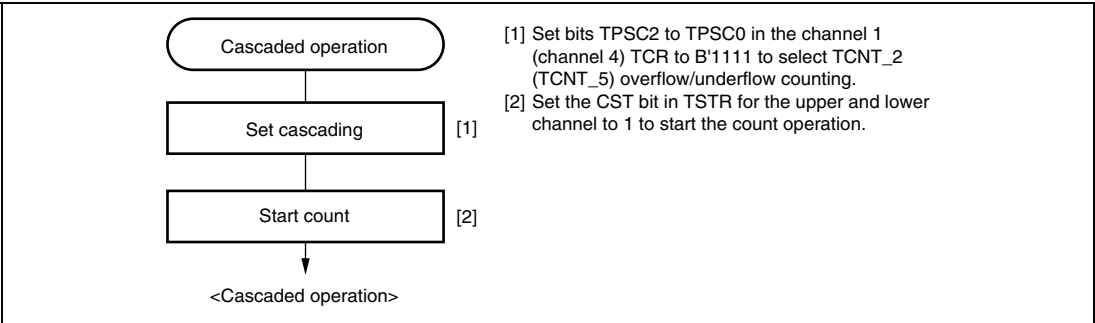

Figure 10.17 Cascaded Operation Setting Procedure

Examples of Cascaded Operation: Figure 10.18 illustrates the operation when counting upon TCNT_2 overflow/underflow has been set for TCNT_1, TGRA_1 and TGRA_2 have been designated as input capture registers, and the TIOC pin rising edge has been selected.

When a rising edge is input to the TIOCA1 and TIOCA2 pins simultaneously, the upper 16 bits of the 32-bit data are transferred to TGRA_1, and the lower 16 bits to TGRA_2.

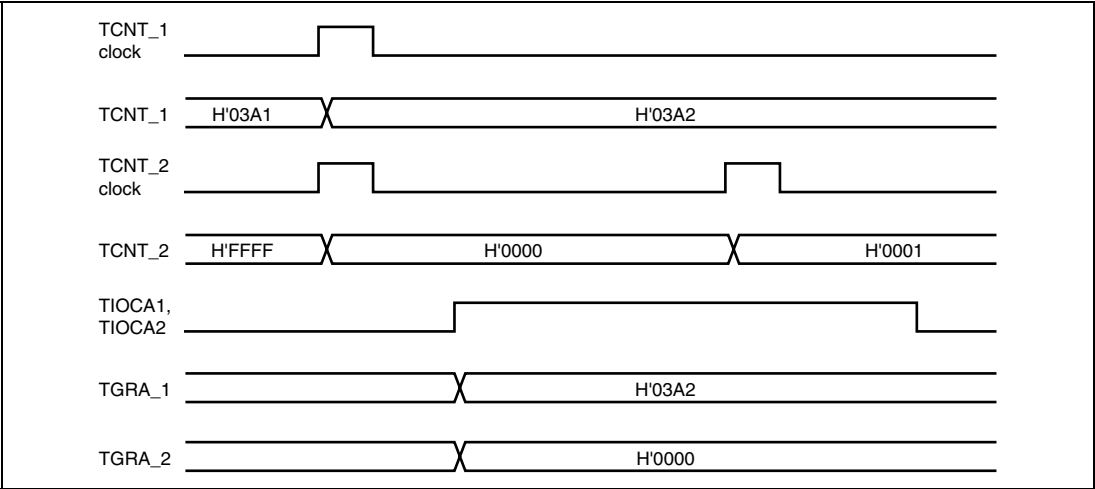

Figure 10.18 Example of Cascaded Operation (1)

Figure 10.19 illustrates the operation when counting upon TCNT_2 overflow/underflow has been set for TCNT_1, and phase counting mode has been designated for channel 2.

TCNT_1 is incremented by TCNT_2 overflow and decremented by TCNT_2 underflow.

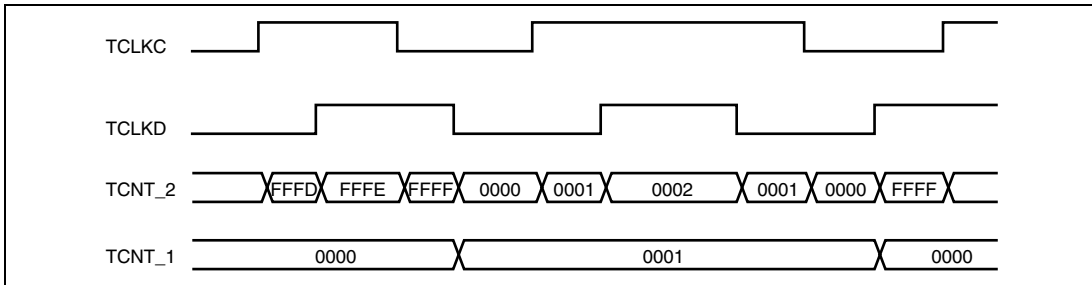

Figure 10.19 Example of Cascaded Operation (2)

10.4.5 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. 0, 1, or toggle output can be selected as the output level in response to compare match of each TGR.

Settings of TGR registers can output a PWM waveform in the range of 0–% to 100–% duty.

Designating TGR compare match as the counter clearing source enables the cycle to be set in that register. All channels can be designated for PWM mode independently. Synchronous operation is also possible.

There are two PWM modes, as described below.

- **PWM mode 1**

PWM output is generated from the TIOCA and TIOCC pins by pairing TGRA with TGRB and TGRC with TGRD. The outputs specified by bits IOA3 to IOA0 and IOC3 to IOC0 in TIOR are output from the TIOCA and TIOCC pins at compare matches A and C, respectively. The outputs specified by bits IOB3 to IOB0 and IOD3 to IOD0 in TIOR are output at compare matches B and D, respectively. The initial output value is the value set in TGRA or TGRC. If the set values of paired TGRs are identical, the output value does not change when a compare match occurs.

In PWM mode 1, a maximum 8-phase PWM output is possible.

- **PWM mode 2**

PWM output is generated using one TGR as the cycle register and the others as duty registers. The output specified in TIOR is performed by means of compare matches. Upon counter clearing by a synchronization register compare match, the output value of each pin is the initial value set in TIOR. If the set values of the cycle and duty registers are identical, the output value does not change when a compare match occurs.

In PWM mode 2, a maximum 15-phase PWM output is possible by combined use with synchronous operation.

The correspondence between PWM output pins and registers is shown in table 10.30.

Table 10.30 PWM Output Registers and Output Pins

Channel	Registers	Output Pins	
		PWM Mode 1	PWM Mode 2
0	TGRA_0	TIOCA0	TIOCA0
	TGRB_0		TIOCB0
	TGRC_0	TIOCC0	TIOCC0
	TGRD_0		TIOCD0
1	TGRA_1	TIOCA1	TIOCA1
	TGRB_1		TIOCB1
2	TGRA_2	TIOCA2	TIOCA2
	TGRB_2		TIOCB2
3	TGRA_3	TIOCA3	TIOCA3
	TGRB_3		TIOCB3
	TGRC_3	TIOCC3	TIOCC3
	TGRD_3		TIOCD3
4	TGRA_4	TIOCA4	TIOCA4
	TGRB_4		TIOCB4
5	TGRA_5	TIOCA5	TIOCA5
	TGRB_5		TIOCB5

Note: In PWM mode 2, PWM output is not possible for the TGR register in which the cycle is set.

Example of PWM Mode Setting Procedure: Figure 10.20 shows an example of the PWM mode setting procedure.

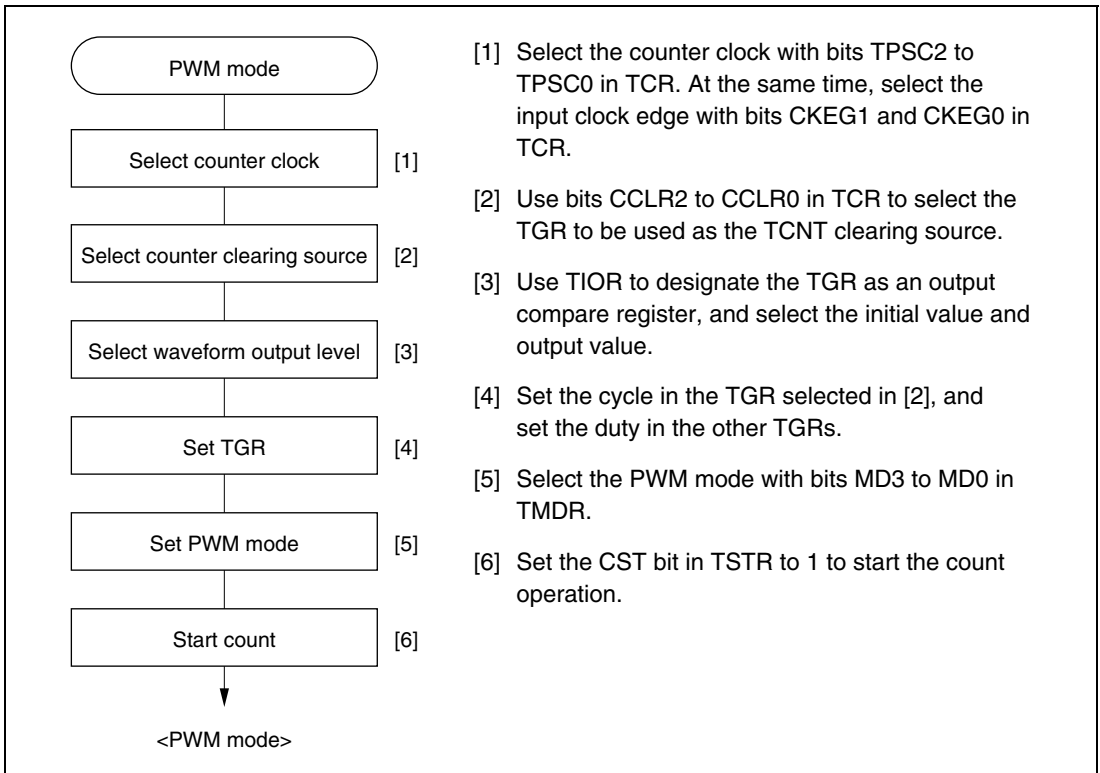

Figure 10.20 Example of PWM Mode Setting Procedure

Examples of PWM Mode Operation: Figure 10.21 shows an example of PWM mode 1 operation.

In this example, TGRA compare match is set as the TCNT clearing source, 0 is set for the TGRA initial output value and output value, and 1 is set as the TGRB output value.

In this case, the value set in TGRA is used as the cycle, and the values set in TGRB registers as the duty.

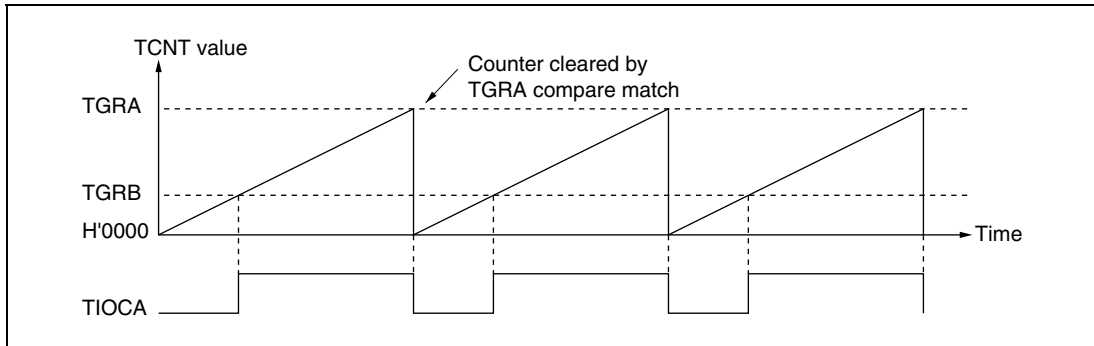

Figure 10.21 Example of PWM Mode Operation (1)

Figure 10.22 shows an example of PWM mode 2 operation.

In this example, synchronous operation is designated for channels 0 and 1, TGRB_1 compare match is set as the TCNT clearing source, and 0 is set for the initial output value and 1 for the output value of the other TGR registers (TGRA_0 to TGRD_0, TGRA_1), to output a 5-phase PWM waveform.

In this case, the value set in TGRB_1 is used as the cycle, and the values set in the other TGRs as the duty.

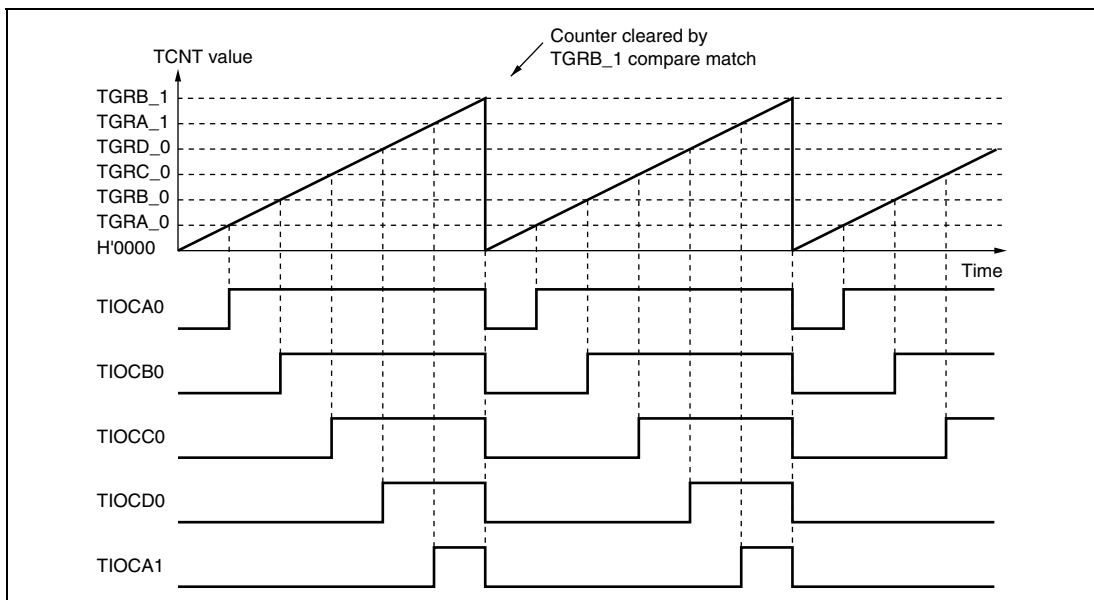

Figure 10.22 Example of PWM Mode Operation (2)

Figure 10.23 shows examples of PWM waveform output with 0% duty and 100% duty in PWM mode.

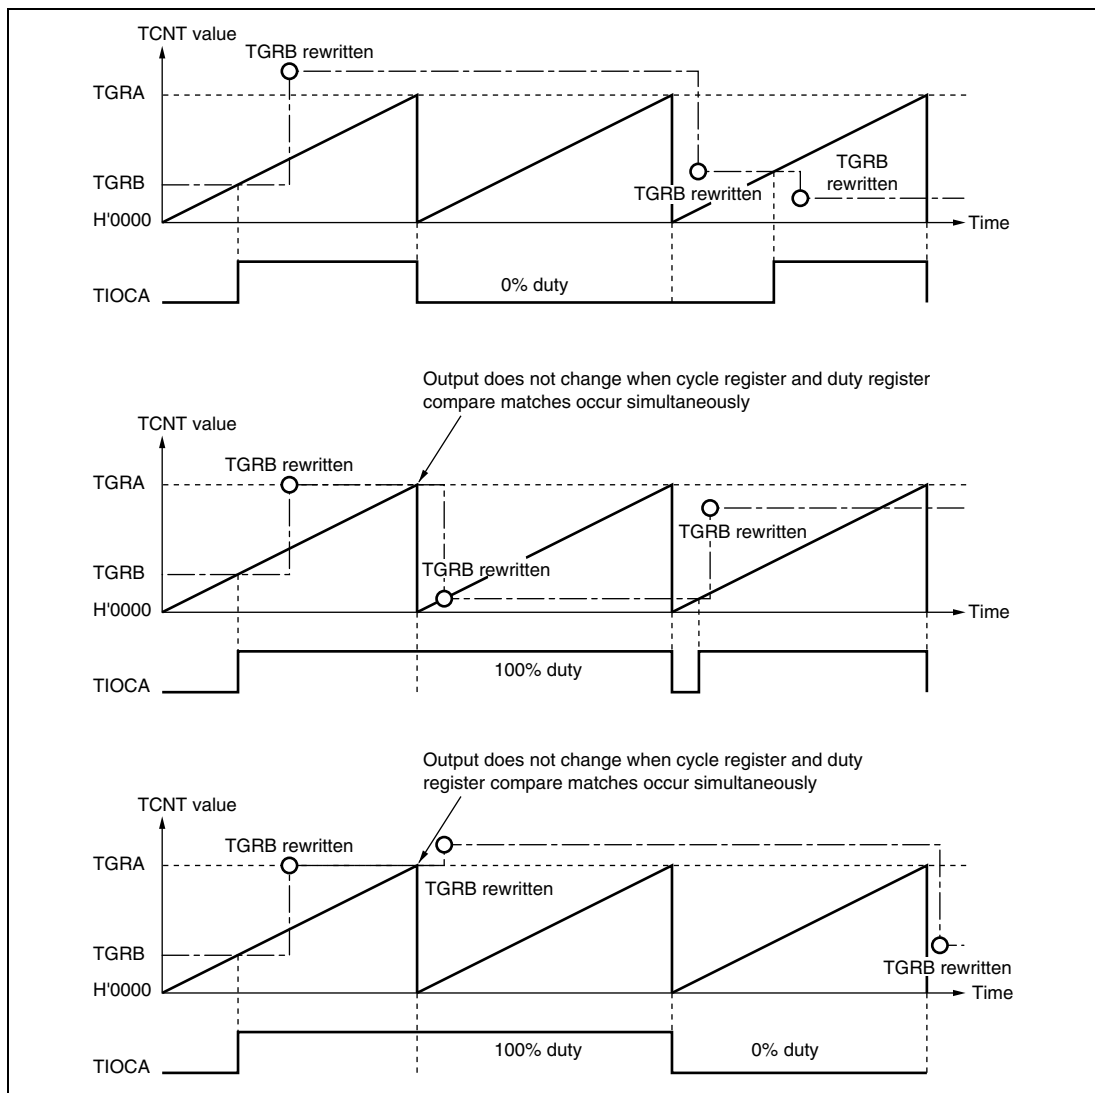

Figure 10.23 Example of PWM Mode Operation (3)

10.4.6 Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected and TCNT is incremented/decremented accordingly. This mode can be set for channels 1, 2, 4, and 5.

When phase counting mode is set, an external clock is selected as the counter input clock and TCNT operates as an up/down-counter regardless of the setting of bits TPSC2 to TPSC0 and bits CKEG1 and CKEG0 in TCR. However, the functions of bits CCLR1 and CCLR0 in TCR, and of TIOR, TIER, and TGR are valid, and input capture/compare match and interrupt functions can be used.

This can be used for two-phase encoder pulse input.

When overflow occurs while TCNT is counting up, the TCFV flag in TSR is set; when underflow occurs while TCNT is counting down, the TCFU flag is set.

The TCFD bit in TSR is the count direction flag. Reading the TCFD flag provides an indication of whether TCNT is counting up or down.

Table 10.31 shows the correspondence between external clock pins and channels.

Table 10.31 Clock Input Pins in Phase Counting Mode

Channels	External Clock Pins	
	A-Phase	B-Phase
When channel 1 or 5 is set to phase counting mode	TCLKA	TCLKB
When channel 2 or 4 is set to phase counting mode	TCLKC	TCLKD

Example of Phase Counting Mode Setting Procedure: Figure 10.24 shows an example of the phase counting mode setting procedure.

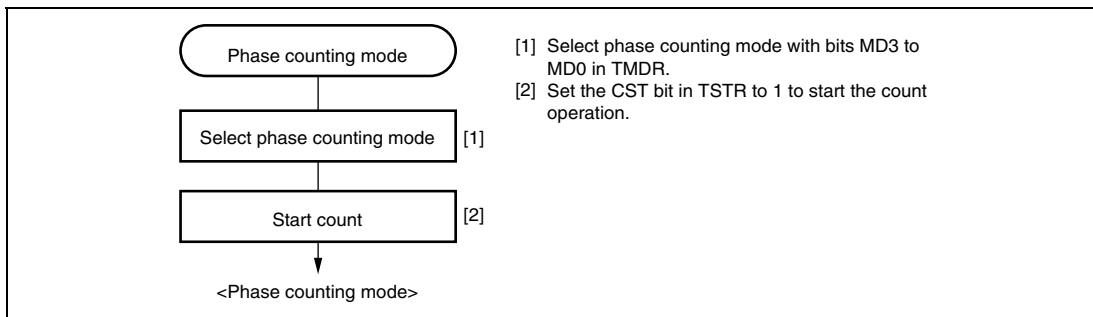

Figure 10.24 Example of Phase Counting Mode Setting Procedure

Examples of Phase Counting Mode Operation: In phase counting mode, TCNT counts up or down according to the phase difference between two external clocks. There are four modes, according to the count conditions.

1. Phase counting mode 1

Figure 10.25 shows an example of phase counting mode 1 operation, and table 10.32 summarizes the TCNT up/down-count conditions.

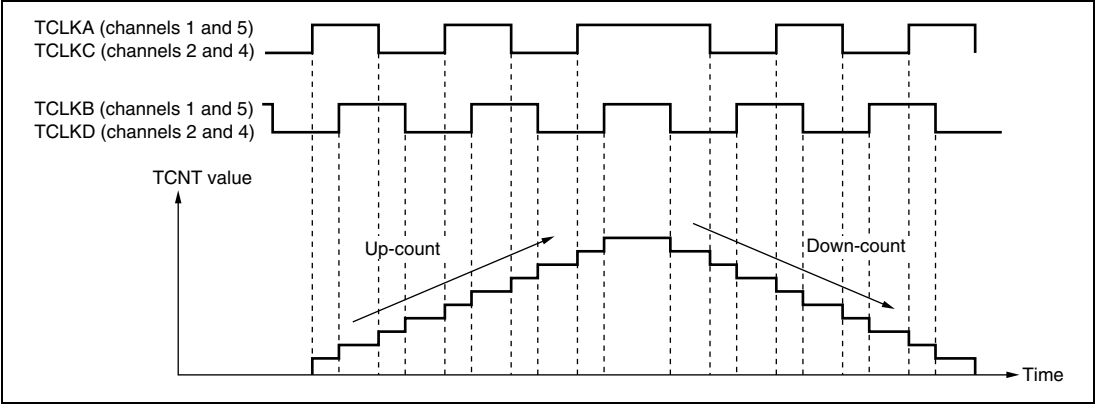

Figure 10.25 Example of Phase Counting Mode 1 Operation

Table 10.32 Up/Down-Count Conditions in Phase Counting Mode 1

Phase Counting Mode Application Example: Figure 10.29 shows an example in which phase counting mode is designated for channel 1, and channel 1 is coupled with channel 0 to input servo motor 2-phase encoder pulses in order to detect the position or speed.

Channel 1 is set to phase counting mode 1, and the encoder pulse A-phase and B-phase are input to TCLKA and TCLKB.

Channel 0 operates with TCNT counter clearing by TGRC_0 compare match; TGRA_0 and TGRC_0 are used for the compare match function, and are set with the speed control cycle and position control cycle. TGRB_0 is used for input capture, with TGRB_0 and TGRD_0 operating in buffer mode. The channel 1 counter input clock is designated as the TGRB_0 input capture source, and detection of the pulse width of 2-phase encoder 4-multiplication pulses is performed.

TGRA_1 and TGRB_1 for channel 1 are designated for input capture, channel 0 TGRA_0 and TGRC_0 compare matches are selected as the input capture source, and the up/down-counter values for the control cycles are stored.

This procedure enables accurate position/speed detection to be achieved.

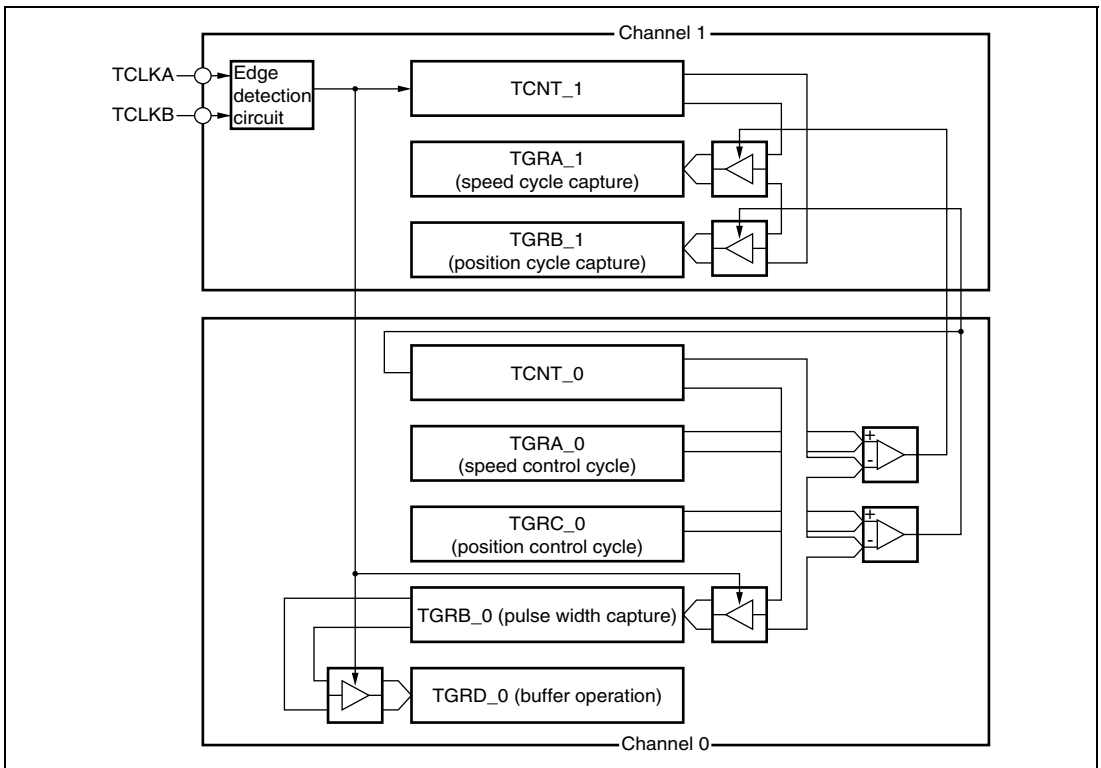

Figure 10.29 Phase Counting Mode Application Example

10.5 Interrupts

There are three kinds of TPU interrupt source: TGR input capture/compare match, TCNT overflow, and TCNT underflow. Each interrupt source has its own status flag and enable/disable bit, allowing generation of interrupt request signals to be enabled or disabled individually.

When an interrupt request is generated, the corresponding status flag in TSR is set to 1. If the corresponding enable/disable bit in TIER is set to 1 at this time, an interrupt is requested. The interrupt request is cleared by clearing the status flag to 0.

Relative channel priorities can be changed by the interrupt controller, but the priority order within a channel is fixed. For details, see section 5, Interrupt Controller.

Table 10.36 lists the TPU interrupt sources.

Table 10.36 TPU Interrupts

Channel	Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC* Activation
0	TGI0A	TGRA_0 input capture/compare match	TGFA_0	Possible	Possible
	TGI0B	TGRB_0 input capture/compare match	TGFB_0	Possible	Not possible
	TGI0C	TGRC_0 input capture/compare match	TGFC_0	Possible	Not possible
	TGI0D	TGRD_0 input capture/compare match	TGFD_0	Possible	Not possible
	TGI0E	TCNT_0 overflow	TCFV_0	Not possible	Not possible
1	TGI1A	TGRA_1 input capture/compare match	TGFA_1	Possible	Possible
	TGI1B	TGRB_1 input capture/compare match	TGFB_1	Possible	Not possible
	TCI1V	TCNT_1 overflow	TCFV_1	Not possible	Not possible
	TCI1U	TCNT_1 underflow	TCFU_1	Not possible	Not possible
2	TGI2A	TGRA_2 input capture/compare match	TGFA_2	Possible	Possible
	TGI2B	TGRB_2 input capture/compare match	TGFB_2	Possible	Not possible
	TCI2V	TCNT_2 overflow	TCFV_2	Not possible	Not possible
	TCI2U	TCNT_2 underflow	TCFU_2	Not possible	Not possible
3	TGI3A	TGRA_3 input capture/compare match	TGFA_3	Possible	Possible
	TGI3B	TGRB_3 input capture/compare match	TGFB_3	Possible	Not possible
	TGI3C	TGRC_3 input capture/compare match	TGFC_3	Possible	Not possible
	TGI3D	TGRD_3 input capture/compare match	TGFD_3	Possible	Not possible
	TCI3V	TCNT_3 overflow	TCFV_3	Not possible	Not possible
4	TGI4A	TGRA_4 input capture/compare match	TGFA_4	Possible	Possible
	TGI4B	TGRB_4 input capture/compare match	TGFB_4	Possible	Not possible
	TCI4V	TCNT_4 overflow	TCFV_4	Not possible	Not possible
	TCI4U	TCNT_4 underflow	TCFU_4	Not possible	Not possible
5	TGI5A	TGRA_5 input capture/compare match	TGFA_5	Possible	Possible
	TGI5B	TGRB_5 input capture/compare match	TGFB_5	Possible	Not possible
	TCI5V	TCNT_5 overflow	TCFV_5	Not possible	Not possible
	TCI5U	TCNT_5 underflow	TCFU_5	Not possible	Not possible

Notes: This table shows the initial state immediately after a reset. The relative channel priorities can be changed by the interrupt controller.

* Not supported by the H8S/2366.

Input Capture/Compare Match Interrupt: An interrupt is requested if the TGIE bit in TIER is set to 1 when the TGF flag in TSR is set to 1 by the occurrence of a TGR input capture/compare match on a particular channel. The interrupt request is cleared by clearing the TGF flag to 0. The TPU has 16 input capture/compare match interrupts, four each for channels 0 and 3, and two each for channels 1, 2, 4, and 5.

Overflow Interrupt: An interrupt is requested if the TCIEV bit in TIER is set to 1 when the TCFV flag in TSR is set to 1 by the occurrence of TCNT overflow on a channel. The interrupt request is cleared by clearing the TCFV flag to 0. The TPU has six overflow interrupts, one for each channel.

Underflow Interrupt: An interrupt is requested if the TCIEU bit in TIER is set to 1 when the TCFU flag in TSR is set to 1 by the occurrence of TCNT underflow on a channel. The interrupt request is cleared by clearing the TCFU flag to 0. The TPU has four underflow interrupts, one each for channels 1, 2, 4, and 5.

10.6 DTC Activation

The DTC can be activated by the TGR input capture/compare match interrupt for a channel. For details, see section 9, Data Transfer Controller (DTC).

A total of 16 TPU input capture/compare match interrupts can be used as DTC activation sources, four each for channels 0 and 3, and two each for channels 1, 2, 4, and 5.

10.7 DMAC Activation

The DMAC can be activated by the TGRA input capture/compare match interrupt for a channel. For details, see section 7, DMA Controller (DMAC).

In the TPU, a total of six TGRA input capture/compare match interrupts can be used as DMAC activation sources, one for each channel.

Note: The DMAC is not supported by the H8S/2366.

10.8 A/D Converter Activation

The A/D converter can be activated by the TGRA input capture/compare match for a channel.

If the TTGE bit in TIER is set to 1 when the TGFA flag in TSR is set to 1 by the occurrence of a TGRA input capture/compare match on a particular channel, a request to start A/D conversion is sent to the A/D converter. If the TPU conversion start trigger has been selected on the A/D converter side at this time, A/D conversion is started.

In the TPU, a total of six TGRA input capture/compare match interrupts can be used as A/D converter conversion start sources, one for each channel.

10.9 Operation Timing

10.9.1 Input/Output Timing

TCNT Count Timing: Figure 10.30 shows TCNT count timing in internal clock operation, and figure 10.31 shows TCNT count timing in external clock operation.

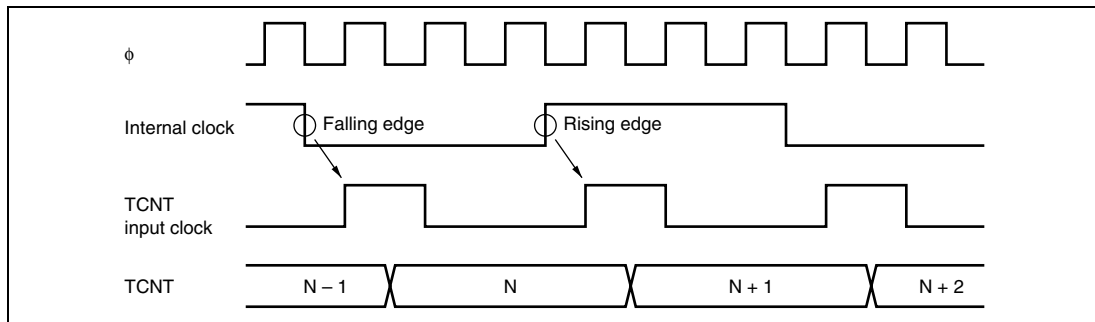

Figure 10.30 Count Timing in Internal Clock Operation

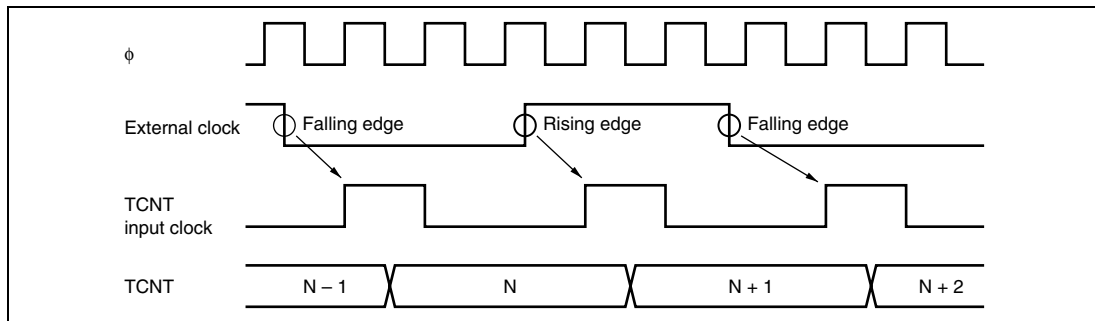

Figure 10.31 Count Timing in External Clock Operation

Output Compare Output Timing: A compare match signal is generated in the final state in which TCNT and TGR match (the point at which the count value matched by TCNT is updated). When a compare match signal is generated, the output value set in TIOR is output at the output compare output pin. After a match between TCNT and TGR, the compare match signal is not generated until the (TIOC pin) TCNT input clock is generated.

Figure 10.32 shows output compare output timing.

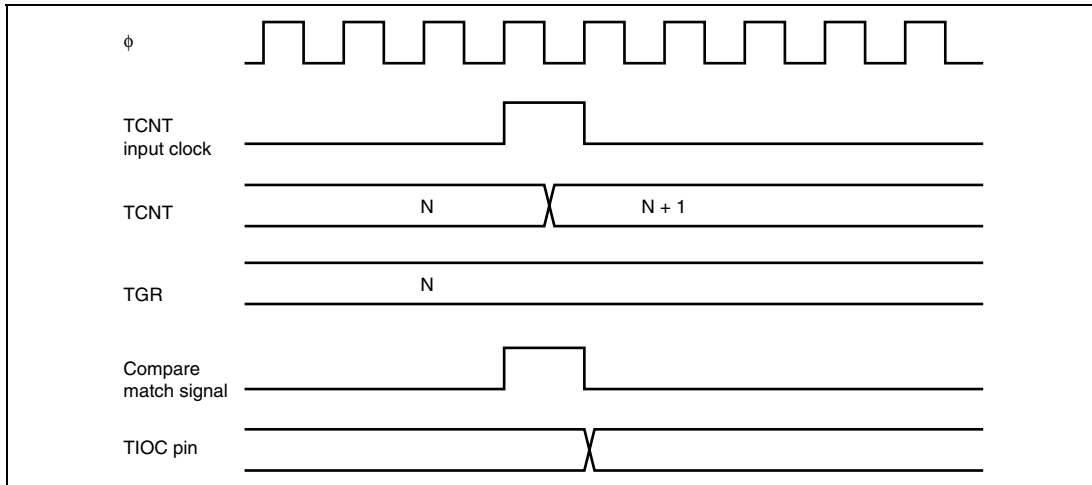

Figure 10.32 Output Compare Output Timing

Input Capture Signal Timing: Figure 10.33 shows input capture signal timing.

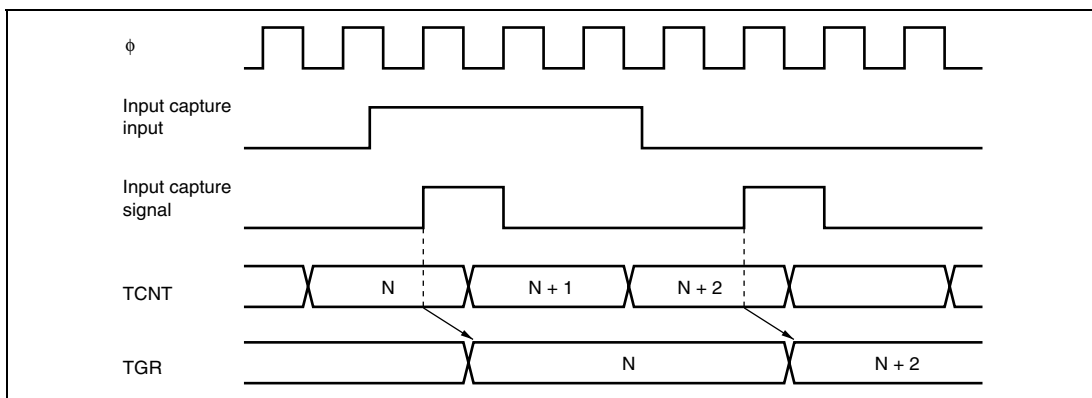

Figure 10.33 Input Capture Input Signal Timing

Timing for Counter Clearing by Compare Match/Input Capture: Figure 10.34 shows the timing when counter clearing by compare match occurrence is specified, and figure 10.35 shows the timing when counter clearing by input capture occurrence is specified.

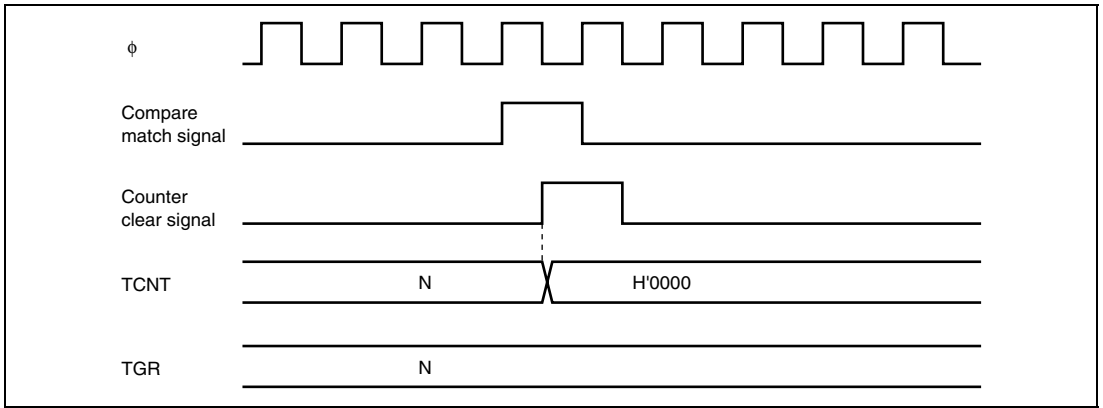

Figure 10.34 Counter Clear Timing (Compare Match)

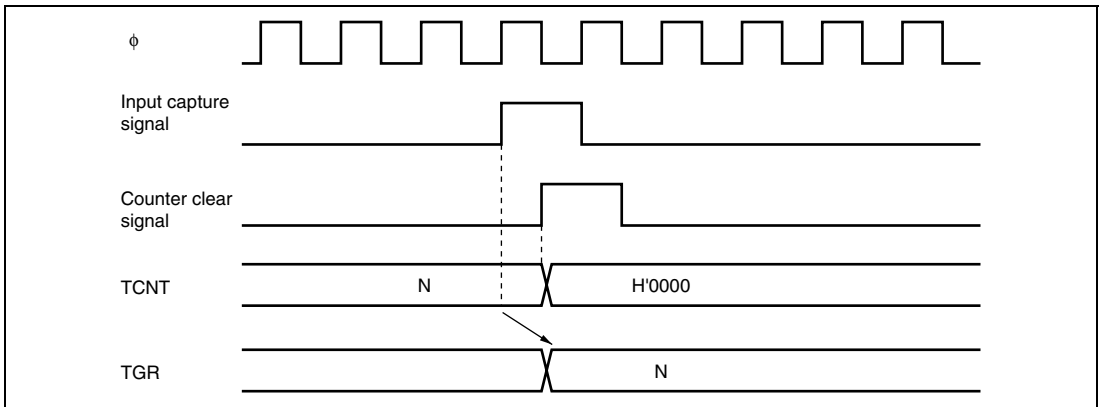

Figure 10.35 Counter Clear Timing (Input Capture)

Buffer Operation Timing: Figures 10.36 and 10.37 show the timings in buffer operation.

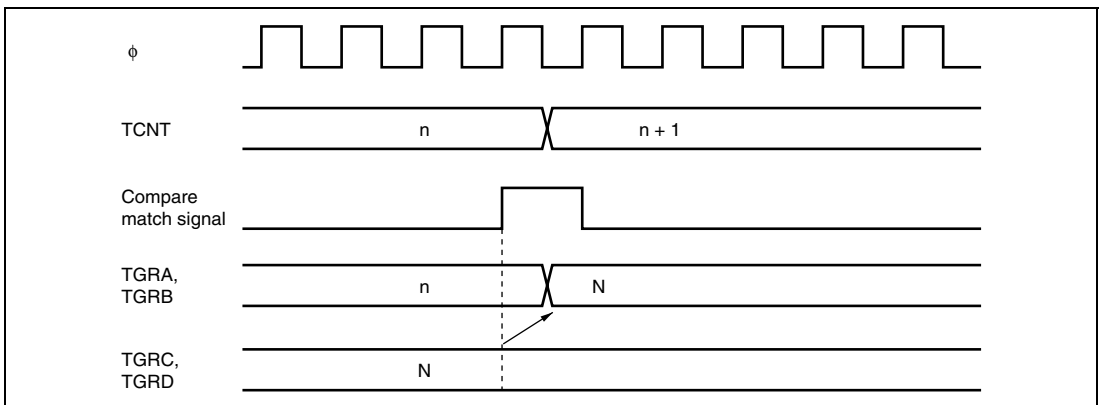

Figure 10.36 Buffer Operation Timing (Compare Match)

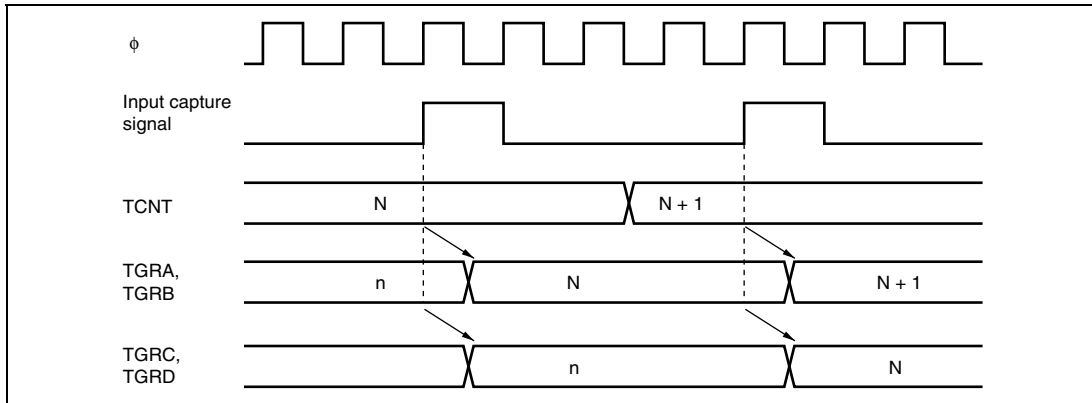

Figure 10.37 Buffer Operation Timing (Input Capture)

10.9.2 Interrupt Signal Timing

TGF Flag Setting Timing in Case of Compare Match: Figure 10.38 shows the timing for setting of the TGF flag in TSR by compare match occurrence, and the TGI interrupt request signal timing.

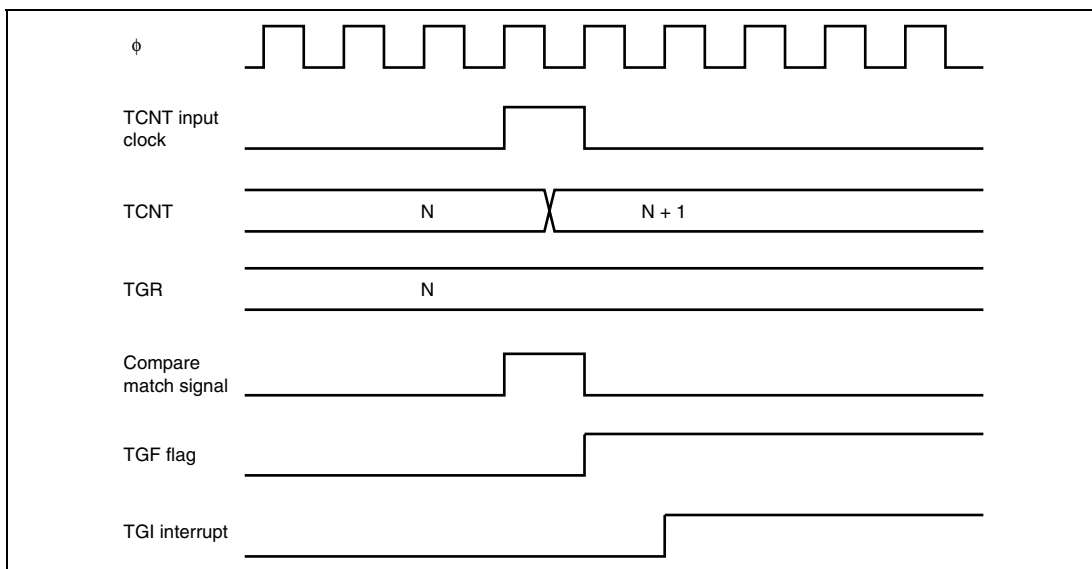

Figure 10.38 TGI Interrupt Timing (Compare Match)

TGF Flag Setting Timing in Case of Input Capture: Figure 10.39 shows the timing for setting of the TGF flag in TSR by input capture occurrence, and the TGI interrupt request signal timing.

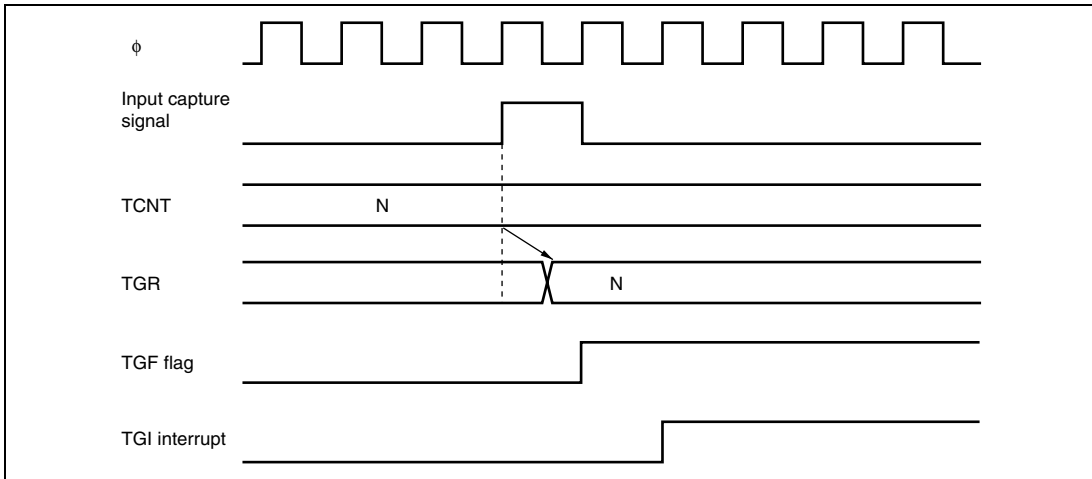

Figure 10.39 TGI Interrupt Timing (Input Capture)

TCFV Flag/TCFU Flag Setting Timing: Figure 10.40 shows the timing for setting of the TCFV flag in TSR by overflow occurrence, and the TCIV interrupt request signal timing.

Figure 10.41 shows the timing for setting of the TCFU flag in TSR by underflow occurrence, and the TCIU interrupt request signal timing.

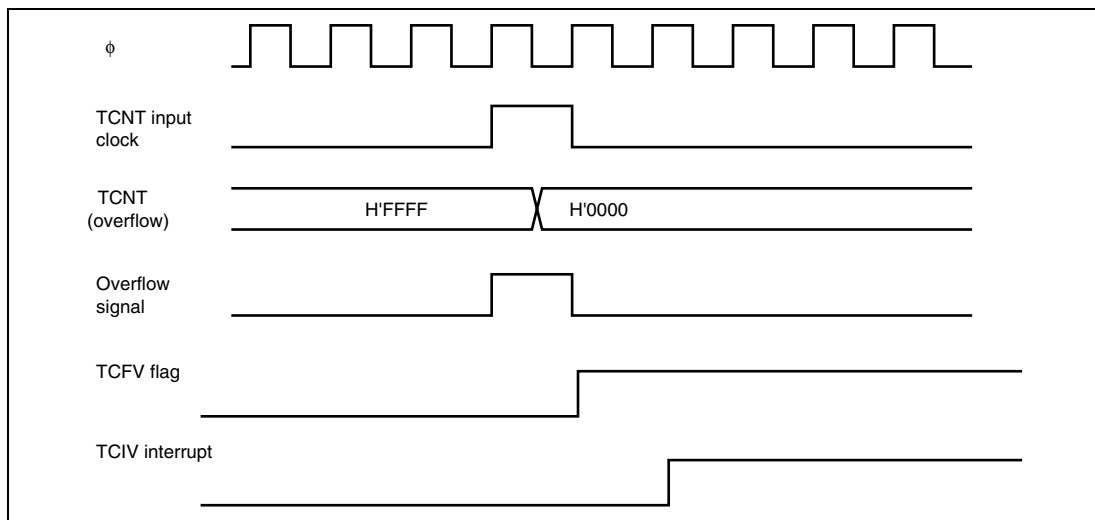

Figure 10.40 TCIV Interrupt Setting Timing

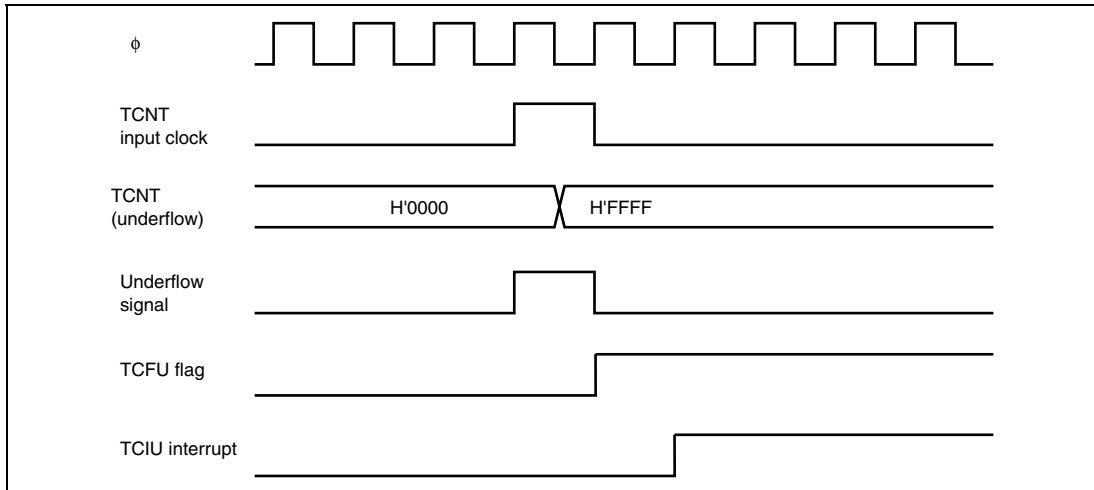

Figure 10.41 TCIU Interrupt Setting Timing

Status Flag Clearing Timing: After a status flag is read as 1 by the CPU, it is cleared by writing 0 to it. When the DTC or DMAC is activated, the flag is cleared automatically. Figure 10.42 shows the timing for status flag clearing by the CPU, and figure 10.43 shows the timing for status flag clearing by the DTC or DMAC*.

Note: * Not supported by the H8S/2366.

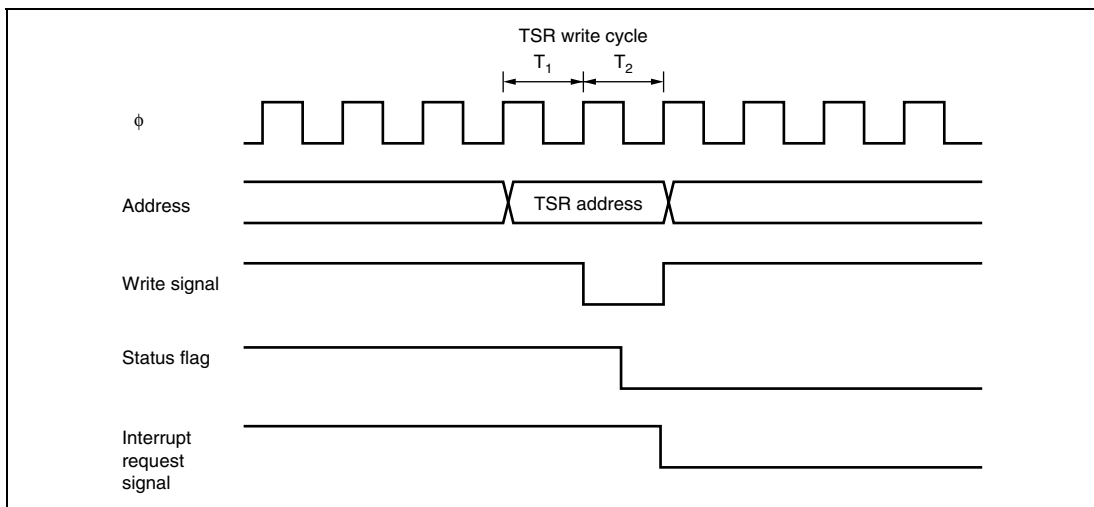

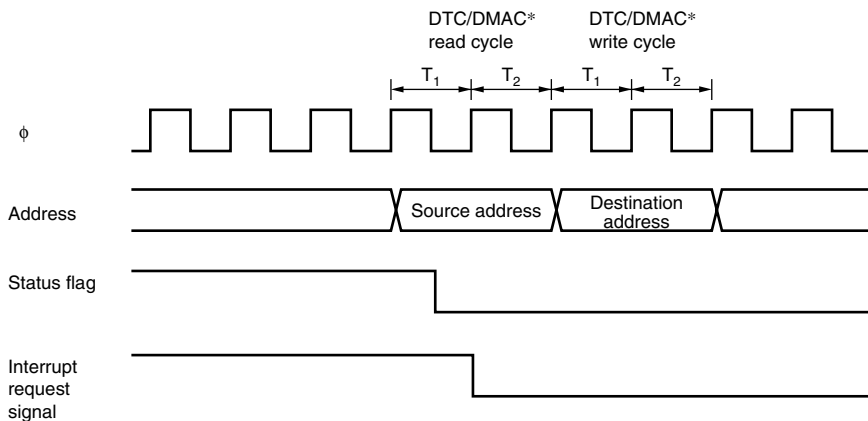

Figure 10.42 Timing for Status Flag Clearing by CPU

Note: * Not supported by the H8S/2366.

Figure 10.43 Timing for Status Flag Clearing by DTC/DMAC* Activation

10.10 Usage Notes

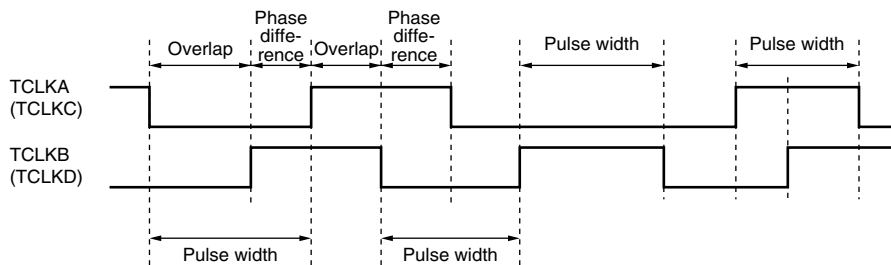

10.10.1 Module Stop Mode Setting

TPU operation can be disabled or enabled using the module stop control register. The initial setting is for TPU operation to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 22, Power-Down Modes.

10.10.2 Input Clock Restrictions

The input clock pulse width must be at least 1.5 states in the case of single-edge detection, and at least 2.5 states in the case of both-edge detection. The TPU will not operate properly with a narrower pulse width.

In phase counting mode, the phase difference and overlap between the two input clocks must be at least 1.5 states, and the pulse width must be at least 2.5 states. Figure 10.44 shows the input clock conditions in phase counting mode.

Notes: Phase difference and overlap : 1.5 states or more
Pulse width : 2.5 states or more

Figure 10.44 Phase Difference, Overlap, and Pulse Width in Phase Counting Mode

10.10.3 Caution on Cycle Setting

When counter clearing by compare match is set, TCNT is cleared in the final state in which it matches the TGR value (the point at which the count value matched by TCNT is updated). Consequently, the actual counter frequency is given by the following formula:

$$f = \frac{\phi}{(N + 1)}$$

Where f: Counter frequency
 ϕ : Operating frequency
N: TGR set value

10.10.4 Contention between TCNT Write and Clear Operations

If the counter clearing signal is generated in the T_2 state of a TCNT write cycle, TCNT clearing takes precedence and the TCNT write is not performed. Figure 10.45 shows the timing in this case.

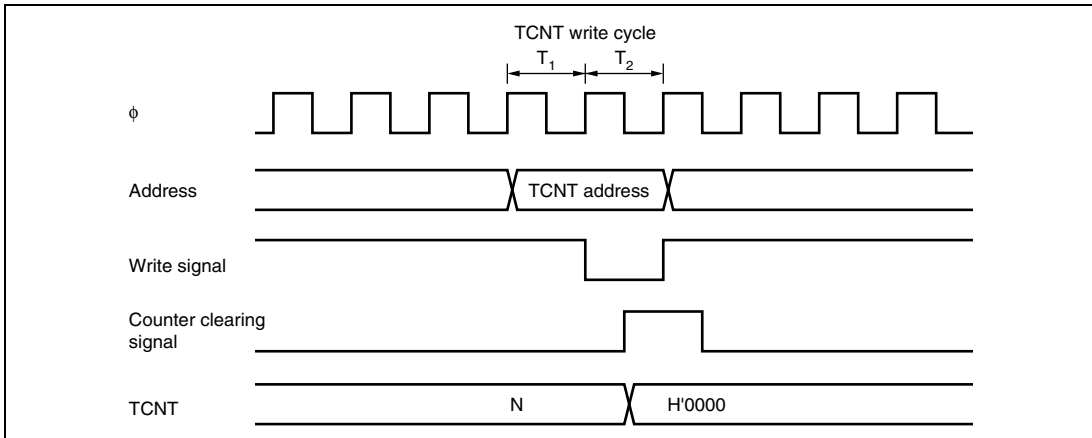

Figure 10.45 Contention between TCNT Write and Clear Operations

10.10.5 Contention between TCNT Write and Increment Operations

If incrementing occurs in the T_2 state of a TCNT write cycle, the TCNT write takes precedence and TCNT is not incremented. Figure 10.46 shows the timing in this case.

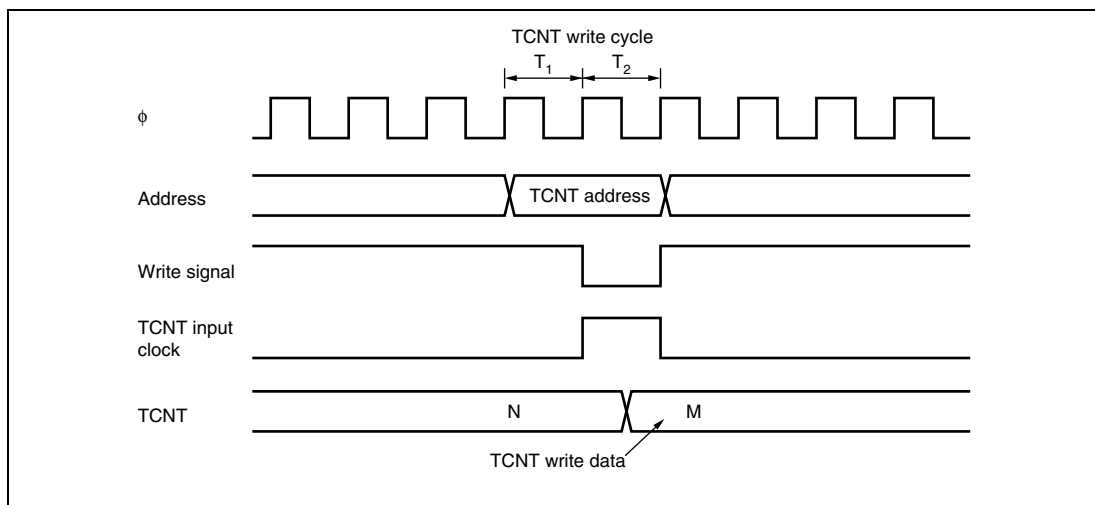

Figure 10.46 Contention between TCNT Write and Increment Operations

10.10.6 Contention between TGR Write and Compare Match

If a compare match occurs in the T_2 state of a TGR write cycle, the TGR write takes precedence and the compare match signal is disabled. A compare match also does not occur when the same value as before is written.

Figure 10.47 shows the timing in this case.

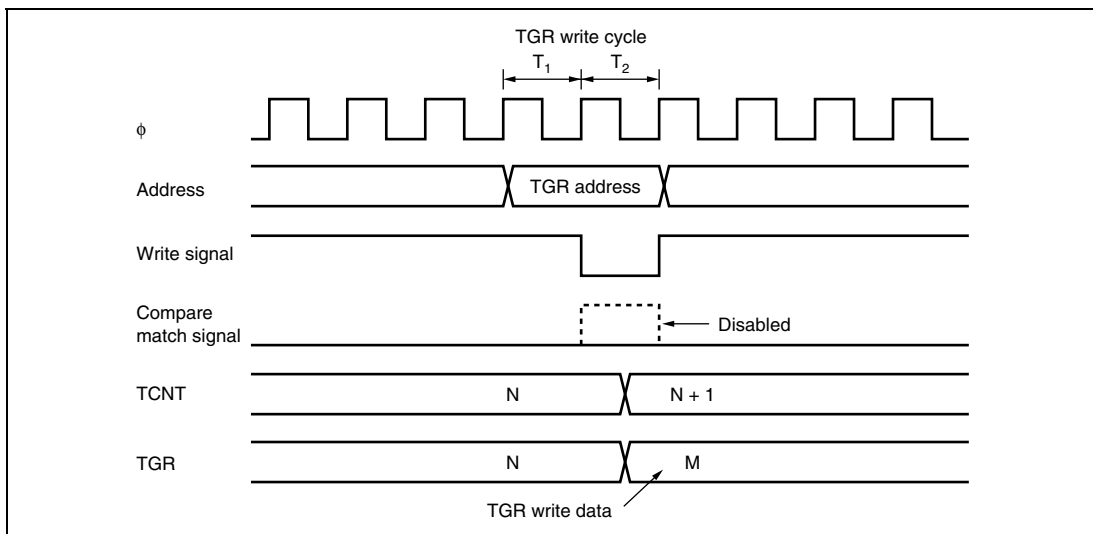

Figure 10.47 Contention between TGR Write and Compare Match

10.10.7 Contention between Buffer Register Write and Compare Match

If a compare match occurs in the T_2 state of a TGR write cycle, the data transferred to TGR by the buffer operation will be the data prior to the write.

Figure 10.48 shows the timing in this case.

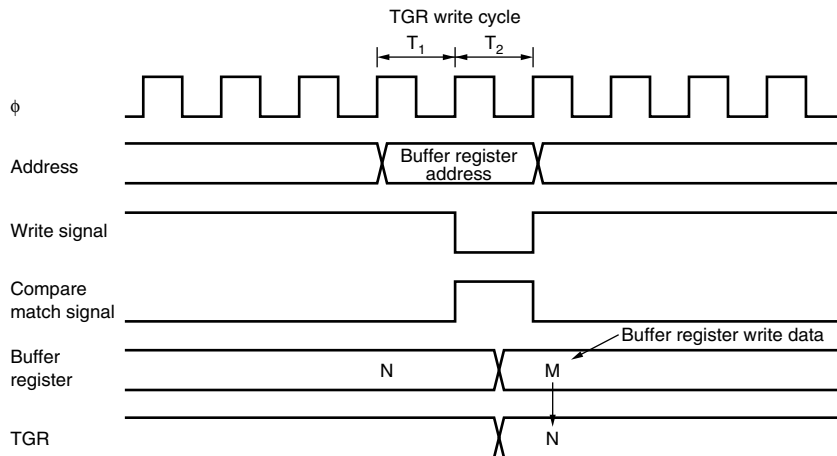

Figure 10.48 Contention between Buffer Register Write and Compare Match

10.10.8 Contention between TGR Read and Input Capture

If the input capture signal is generated in the T_1 state of a TGR read cycle, the data that is read will be the data after input capture transfer.

Figure 10.49 shows the timing in this case.

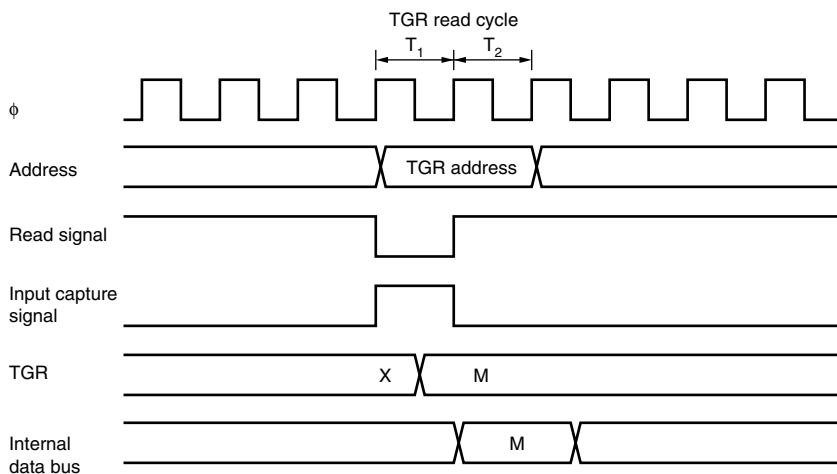

Figure 10.49 Contention between TGR Read and Input Capture

10.10.9 Contention between TGR Write and Input Capture

If the input capture signal is generated in the T_2 state of a TGR write cycle, the input capture operation takes precedence and the write to TGR is not performed.

Figure 10.50 shows the timing in this case.

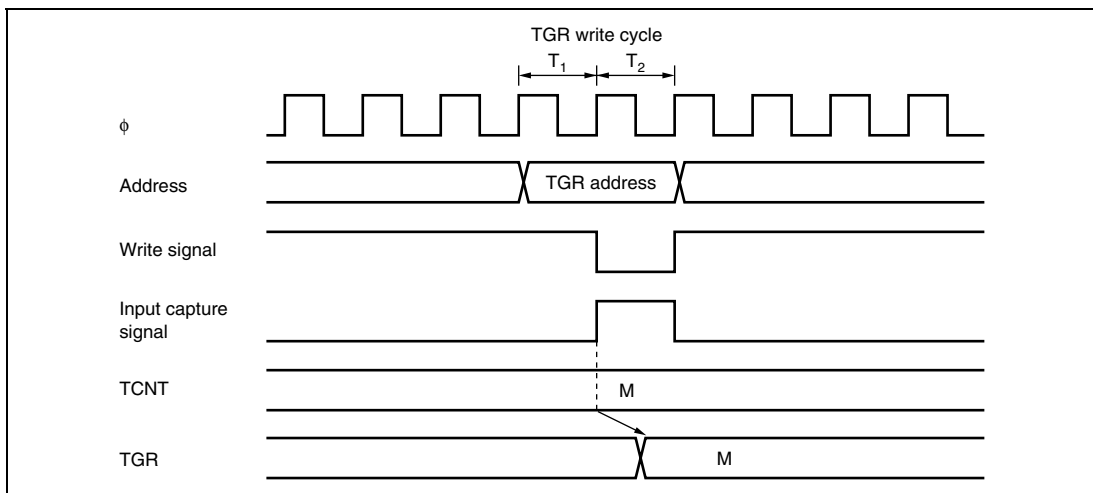

Figure 10.50 Contention between TGR Write and Input Capture

10.10.10 Contention between Buffer Register Write and Input Capture

If the input capture signal is generated in the T_2 state of a buffer register write cycle, the buffer operation takes precedence and the write to the buffer register is not performed.

Figure 10.51 shows the timing in this case.

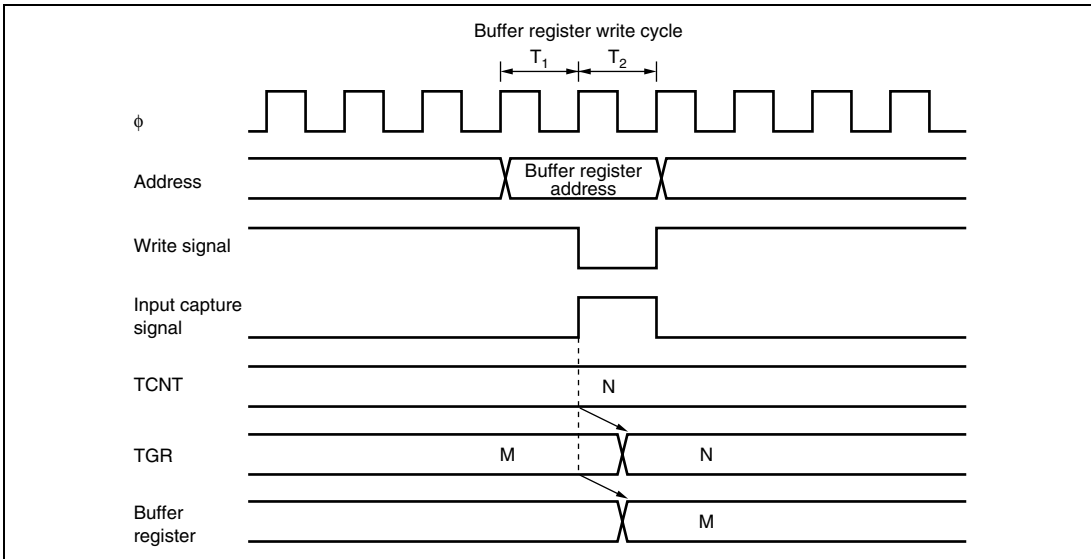

Figure 10.51 Contention between Buffer Register Write and Input Capture

10.10.11 Contention between Overflow/Underflow and Counter Clearing

If overflow/underflow and counter clearing occur simultaneously, the TCFV/TCFU flag in TSR is not set and TCNT clearing takes precedence.

Figure 10.52 shows the operation timing when a TGR compare match is specified as the clearing source, and H'FFFF is set in TGR.

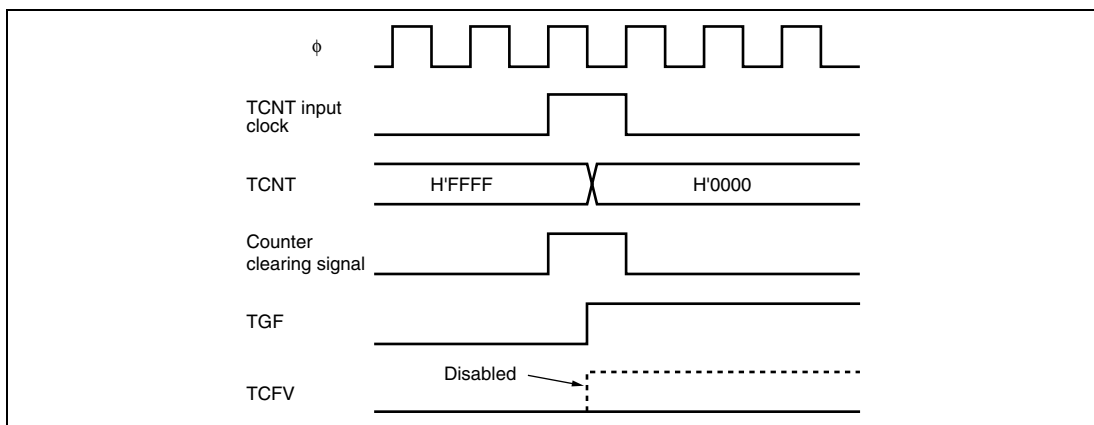

Figure 10.52 Contention between Overflow and Counter Clearing

10.10.12 Contention between TCNT Write and Overflow/Underflow

If there is an up-count or down-count in the T_2 state of a TCNT write cycle, when overflow/underflow occurs, the TCNT write takes precedence and the TCFV/TCFU flag in TSR is not set.

Figure 10.53 shows the operation timing when there is contention between TCNT write and overflow.

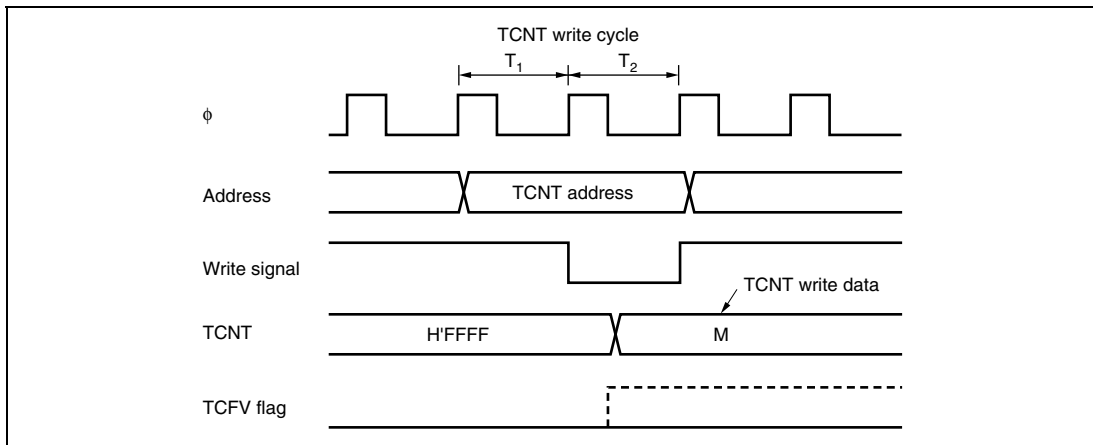

Figure 10.53 Contention between TCNT Write and Overflow

10.10.13 Multiplexing of I/O Pins

In this LSI, the TCLKA input pin is multiplexed with the TIOCC0 I/O pin, the TCLKB input pin with the TIOCD0 I/O pin, the TCLKC input pin with the TIOCB1 I/O pin, and the TCLKD input pin with the TIOCB2 I/O pin. When an external clock is input, compare match output should not be performed from a multiplexed pin.

10.10.14 Interrupts and Module Stop Mode

If module stop mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DMAC* or DTC activation source. Interrupts should therefore be disabled before entering module stop mode.

Note: * Not supported by the H8S/2366.

Section 11 Programmable Pulse Generator (PPG)

The programmable pulse generator (PPG)* provides pulse outputs by using the 16-bit timer pulse unit (TPU) as a time base. The PPG pulse outputs are divided into 4-bit groups (groups 3 to 0) that can operate both simultaneously and independently. The block diagram of PPG is shown in figure 11.1

Note: * The PPG is not supported by the H8S/2366.

11.1 Features

- 16-bit output data
- Four output groups
- Selectable output trigger signals
- Non-overlap mode
- Can operate together with the data transfer controller (DTC) and the DMA controller (DMAC)
- Settable inverted output
- Module stop mode can be set

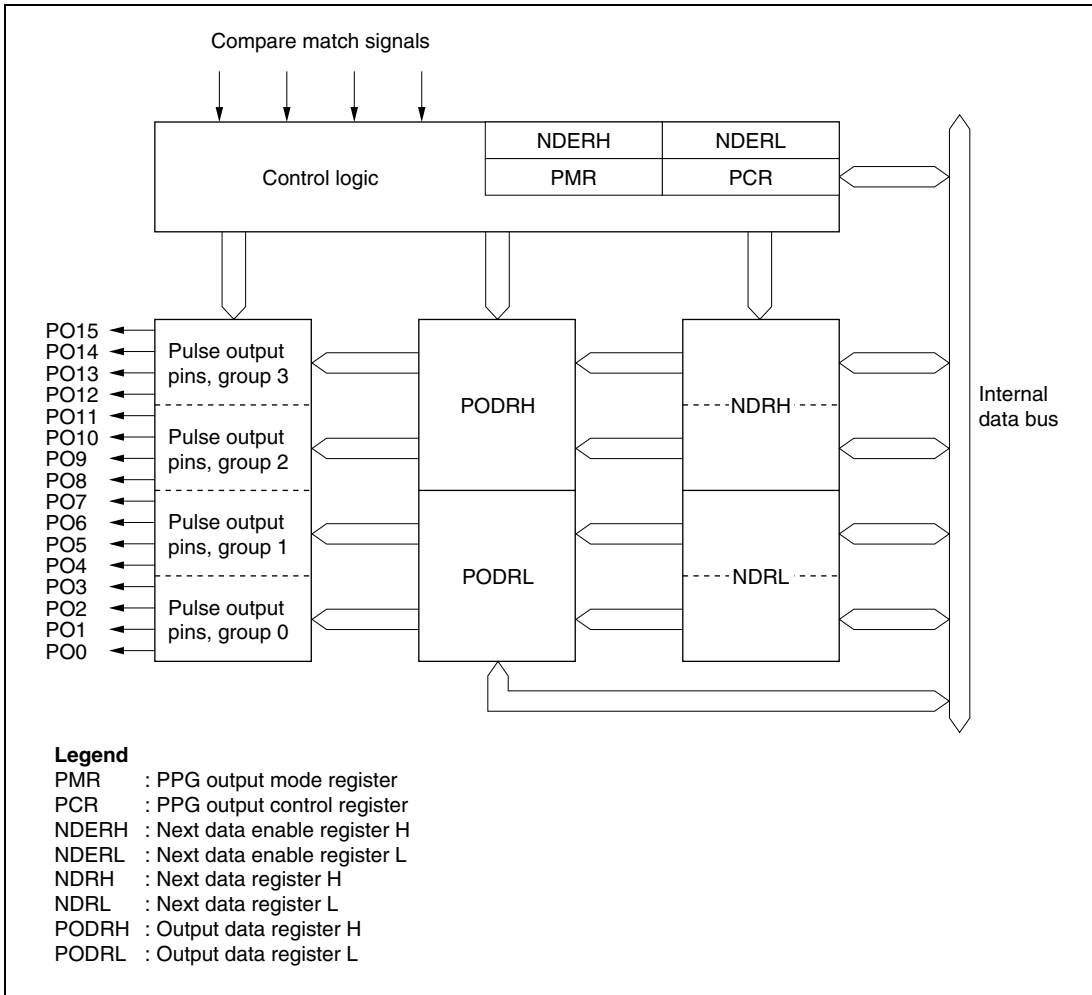

Figure 11.1 Block Diagram of PPG

11.2 Input/Output Pins

Table 11.1 summarizes the I/O pins of the PPG.

Table 11.1 Pin Configuration

Pin Name	I/O	Function
PO15	Output	Group 3 pulse output
PO14	Output	
PO13	Output	
PO12	Output	
PO11	Output	Group 2 pulse output
PO10	Output	
PO9	Output	
PO8	Output	
PO7	Output	Group 1 pulse output
PO6	Output	
PO5	Output	
PO4	Output	
PO3	Output	Group 0 pulse output
PO2	Output	
PO1	Output	
PO0	Output	

11.3 Register Descriptions

The PPG has the following registers.

- Next data enable register H (NDERH)
- Next data enable register L (NDERL)
- Output data register H (PODRH)
- Output data register L (PODRL)
- Next data register H (NDRH)
- Next data register L (NDRL)
- PPG output control register (PCR)
- PPG output mode register (PMR)

11.3.1 Next Data Enable Registers H, L (NDERH, NDERL)

NDERH, NDERL enable or disable pulse output on a bit-by-bit basis. For outputting pulse by the PPG, set the corresponding DDR to 1.

- NDERH

Bit	Bit Name	Initial Value	R/W	Description
7	NDER15	0	R/W	Next Data Enable 15 to 8
6	NDER14	0	R/W	When a bit is set to 1, the value in the corresponding NDRH bit is transferred to the PODRH bit by the selected output trigger. Values are not transferred from NDRH to PODRH for cleared bits.
5	NDER13	0	R/W	
4	NDER12	0	R/W	
3	NDER11	0	R/W	
2	NDER10	0	R/W	
1	NDER9	0	R/W	
0	NDER8	0	R/W	

- NDERL

Bit	Bit Name	Initial Value	R/W	Description
7	NDER7	0	R/W	Next Data Enable 7 to 0
6	NDER6	0	R/W	When a bit is set to 1, the value in the corresponding NDRL bit is transferred to the PODRL bit by the selected output trigger. Values are not transferred from NDRL to PODRL for cleared bits.
5	NDER5	0	R/W	
4	NDER4	0	R/W	
3	NDER3	0	R/W	
2	NDER2	0	R/W	
1	NDER1	0	R/W	
0	NDER0	0	R/W	

11.3.2 Output Data Registers H, L (PODRH, PODRL)

PODRH and PODRL store output data for use in pulse output. A bit that has been set for pulse output by NDER is read-only and cannot be modified.

- PODRH

Bit	Bit Name	Initial Value	R/W	Description
7	POD15	0	R/W	Output Data Register 15 to 8
6	POD14	0	R/W	For bits which have been set to pulse output by NDERH, the output trigger transfers NDRH values to this register during PPG operation. While NDERH is set to 1, the CPU cannot write to this register. While NDERH is cleared, the initial output value of the pulse can be set.
5	POD13	0	R/W	
4	POD12	0	R/W	
3	POD11	0	R/W	
2	POD10	0	R/W	
1	POD9	0	R/W	
0	POD8	0	R/W	

- PODRL

Bit	Bit Name	Initial Value	R/W	Description
7	POD7	0	R/W	Output Data Register 7 to 0
6	POD6	0	R/W	For bits which have been set to pulse output by NDERL, the output trigger transfers NDRL values to this register during PPG operation. While NDERL is set to 1, the CPU cannot write to this register. While NDERL is cleared, the initial output value of the pulse can be set.
5	POD5	0	R/W	
4	POD4	0	R/W	
3	POD3	0	R/W	
2	POD2	0	R/W	
1	POD1	0	R/W	
0	POD0	0	R/W	

11.3.3 Next Data Registers H, L (NDRH, NDRL)

NDRH, NDRL store the next data for pulse output. The NDR addresses differ depending on whether pulse output groups have the same output trigger or different output triggers.

- NDRH

If pulse output groups 2 and 3 have the same output trigger, all eight bits are mapped to the same address and can be accessed at one time, as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR15	0	R/W	Next Data Register 15 to 8
6	NDR14	0	R/W	The register contents are transferred to the corresponding PODRH bits by the output trigger specified with PCR.
5	NDR13	0	R/W	
4	NDR12	0	R/W	
3	NDR11	0	R/W	
2	NDR10	0	R/W	
1	NDR9	0	R/W	
0	NDR8	0	R/W	

If pulse output groups 2 and 3 have different output triggers, upper 4 bits and lower 4 bits are mapped to the different addresses as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR15	0	R/W	Next Data Register 15 to 12
6	NDR14	0	R/W	The register contents are transferred to the corresponding PODRH bits by the output trigger specified with PCR.
5	NDR13	0	R/W	
4	NDR12	0	R/W	
3 to 0	—	1	—	Reserved These bits are always read as 1 and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	1	—	Reserved These bits are always read as 1 and cannot be modified.
3	NDR11	0	R/W	Next Data Register 11 to 8
2	NDR10	0	R/W	The register contents are transferred to the corresponding PODRH bits by the output trigger specified with PCR.
1	NDR9	0	R/W	
0	NDR8	0	R/W	

- NDRL

If pulse output groups 0 and 1 have the same output trigger, all eight bits are mapped to the same address and can be accessed at one time, as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR7	0	R/W	Next Data Register 7 to 0
6	NDR6	0	R/W	The register contents are transferred to the corresponding PODRL bits by the output trigger specified with PCR.
5	NDR5	0	R/W	
4	NDR4	0	R/W	
3	NDR3	0	R/W	
2	NDR2	0	R/W	
1	NDR1	0	R/W	
0	NDR0	0	R/W	

If pulse output groups 0 and 1 have different output triggers, upper 4 bits and lower 4 bits are mapped to the different addresses as shown below.

Bit	Bit Name	Initial Value	R/W	Description
7	NDR7	0	R/W	Next Data Register 7 to 4
6	NDR6	0	R/W	The register contents are transferred to the corresponding PODRL bits by the output trigger specified with PCR.
5	NDR5	0	R/W	
4	NDR4	0	R/W	
3 to 0	—	1	—	Reserved These bits are always read as 1 and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	1	—	Reserved These bits are always read as 1 and cannot be modified.
3	NDR3	0	R/W	Next Data Register 3 to 0
2	NDR2	0	R/W	The register contents are transferred to the corresponding PODRL bits by the output trigger specified with PCR.
1	NDR1	0	R/W	
0	NDR0	0	R/W	

11.3.4 PPG Output Control Register (PCR)

PCR selects output trigger signals on a group-by-group basis. For details on output trigger selection, refer to section 11.3.5, PPG Output Mode Register (PMR).

Bit	Bit Name	Initial Value	R/W	Description
7	G3CMS1	1	R/W	Group 3 Compare Match Select 1 and 0
6	G3CMS0	1	R/W	Select output trigger of pulse output group 3. 00: Compare match in TPU channel 0 01: Compare match in TPU channel 1 10: Compare match in TPU channel 2 11: Compare match in TPU channel 3
5	G2CMS1	1	R/W	Group 2 Compare Match Select 1 and 0
4	G2CMS0	1	R/W	Select output trigger of pulse output group 2. 00: Compare match in TPU channel 0 01: Compare match in TPU channel 1 10: Compare match in TPU channel 2 11: Compare match in TPU channel 3
3	G1CMS1	1	R/W	Group 1 Compare Match Select 1 and 0
2	G1CMS0	1	R/W	Select output trigger of pulse output group 1. 00: Compare match in TPU channel 0 01: Compare match in TPU channel 1 10: Compare match in TPU channel 2 11: Compare match in TPU channel 3

Bit	Bit Name	Initial Value	R/W	Description
1	G0CMS1	1	R/W	Group 0 Compare Match Select 1 and 0
0	G0CMS0	1	R/W	Select output trigger of pulse output group 0. 00: Compare match in TPU channel 0 01: Compare match in TPU channel 1 10: Compare match in TPU channel 2 11: Compare match in TPU channel 3

11.3.5 PPG Output Mode Register (PMR)

PMR selects the pulse output mode of the PPG for each group. If inverted output is selected, a low-level pulse is output when PODRH is 1 and a high-level pulse is output when PODRH is 0. If non-overlapping operation is selected, PPG updates its output values at compare match A or B of the TPU that becomes the output trigger. For details, refer to section 11.4.4, Non-Overlapping Pulse Output.

Bit	Bit Name	Initial Value	R/W	Description
7	G3INV	1	R/W	Group 3 Inversion Selects direct output or inverted output for pulse output group 3. 0: Inverted output 1: Direct output
6	G2INV	1	R/W	Group 2 Inversion Selects direct output or inverted output for pulse output group 2. 0: Inverted output 1: Direct output
5	G1INV	1	R/W	Group 1 Inversion Selects direct output or inverted output for pulse output group 1. 0: Inverted output 1: Direct output
4	G0INV	1	R/W	Group 0 Inversion Selects direct output or inverted output for pulse output group 0. 0: Inverted output 1: Direct output

Bit	Bit Name	Initial Value	R/W	Description
3	G3NOV	0	R/W	<p>Group 3 Non-Overlap</p> <p>Selects normal or non-overlapping operation for pulse output group 3.</p> <p>0: Normal operation (output values updated at compare match A in the selected TPU channel)</p> <p>1: Non-overlapping operation (output values updated at compare match A or B in the selected TPU channel)</p>
2	G2NOV	0	R/W	<p>Group 2 Non-Overlap</p> <p>Selects normal or non-overlapping operation for pulse output group 2.</p> <p>0: Normal operation (output values updated at compare match A in the selected TPU channel)</p> <p>1: Non-overlapping operation (output values updated at compare match A or B in the selected TPU channel)</p>
1	G1NOV	0	R/W	<p>Group 1 Non-Overlap</p> <p>Selects normal or non-overlapping operation for pulse output group 1.</p> <p>0: Normal operation (output values updated at compare match A in the selected TPU channel)</p> <p>1: Non-overlapping operation (output values updated at compare match A or B in the selected TPU channel)</p>

11.4 Operation

Figure 11.2 shows an overview diagram of the PPG. PPG pulse output is enabled when the corresponding bits in P1DDR, P2DDR, and NDER are set to 1. An initial output value is determined by its corresponding PODR initial setting. When the compare match event specified by PCR occurs, the corresponding NDR bit contents are transferred to PODR to update the output values. Sequential output of data of up to 16 bits is possible by writing new output data to NDR before the next compare match.

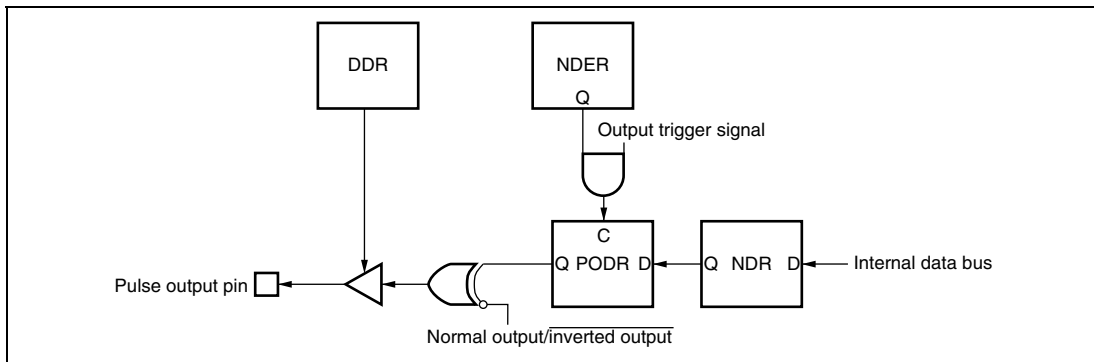

Figure 11.2 Overview Diagram of PPG

11.4.1 Output Timing

If pulse output is enabled, NDR contents are transferred to PODR and output when the specified compare match event occurs. Figure 11.3 shows the timing of these operations for the case of normal output in groups 2 and 3, triggered by compare match A.

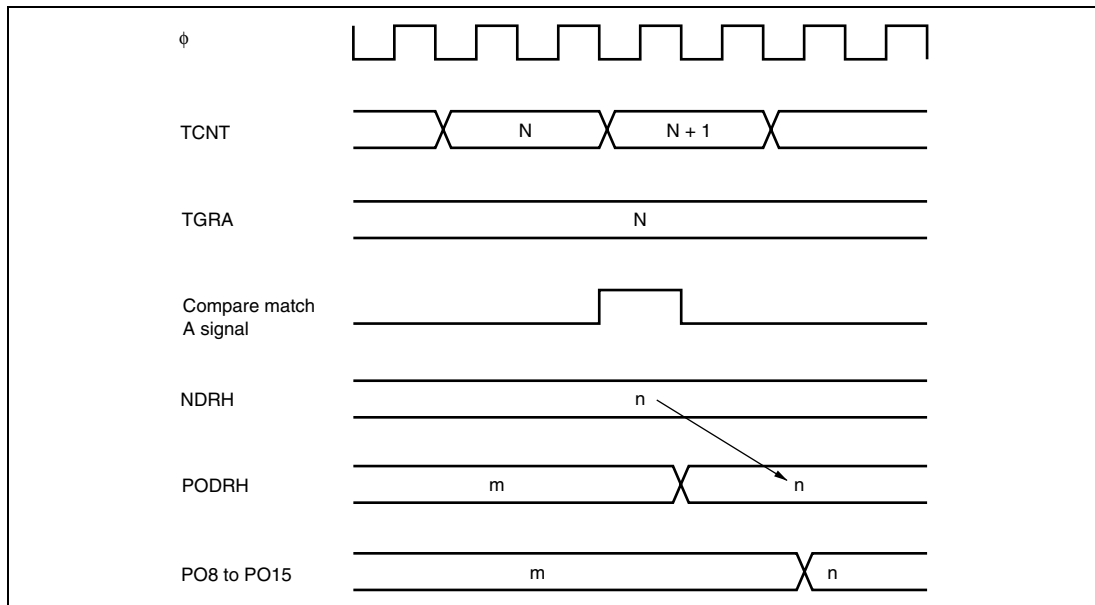

Figure 11.3 Timing of Transfer and Output of NDR Contents (Example)

11.4.2 Sample Setup Procedure for Normal Pulse Output

Figure 11.4 shows a sample procedure for setting up normal pulse output.

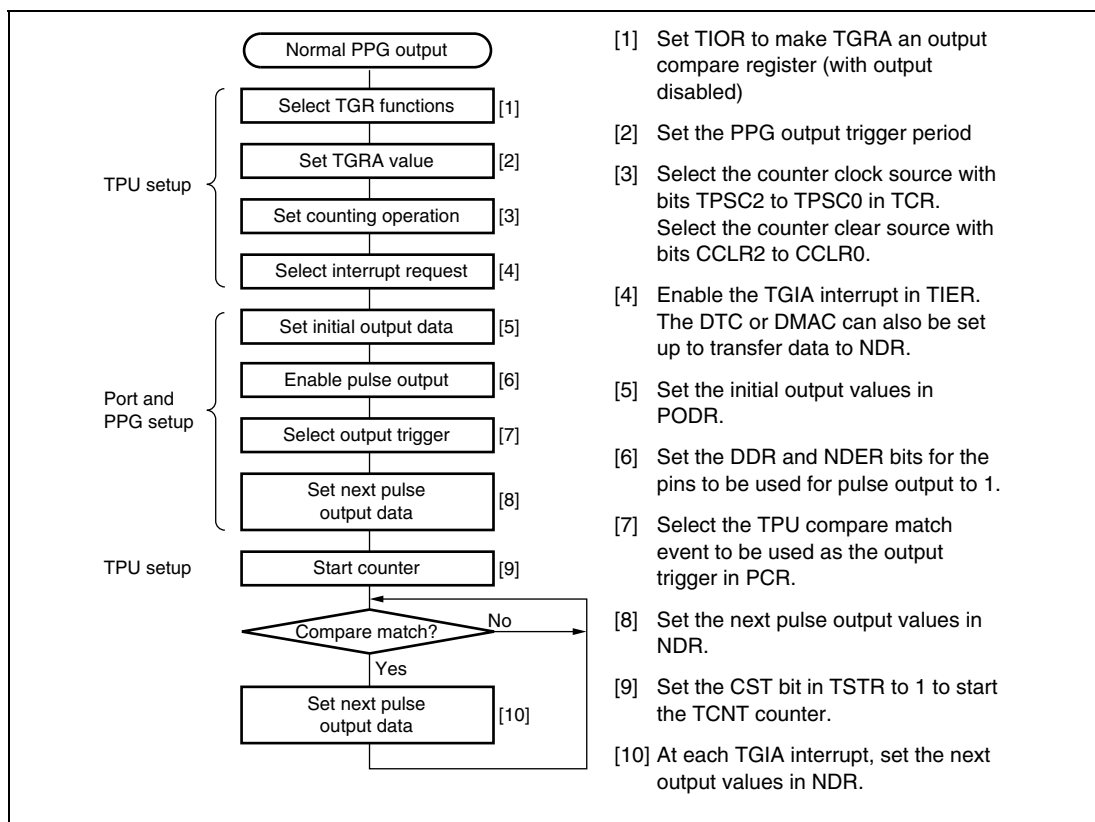

Figure 11.4 Setup Procedure for Normal Pulse Output (Example)

11.4.3 Example of Normal Pulse Output (Example of Five-Phase Pulse Output)

Figure 11.5 shows an example in which pulse output is used for cyclic five-phase pulse output.

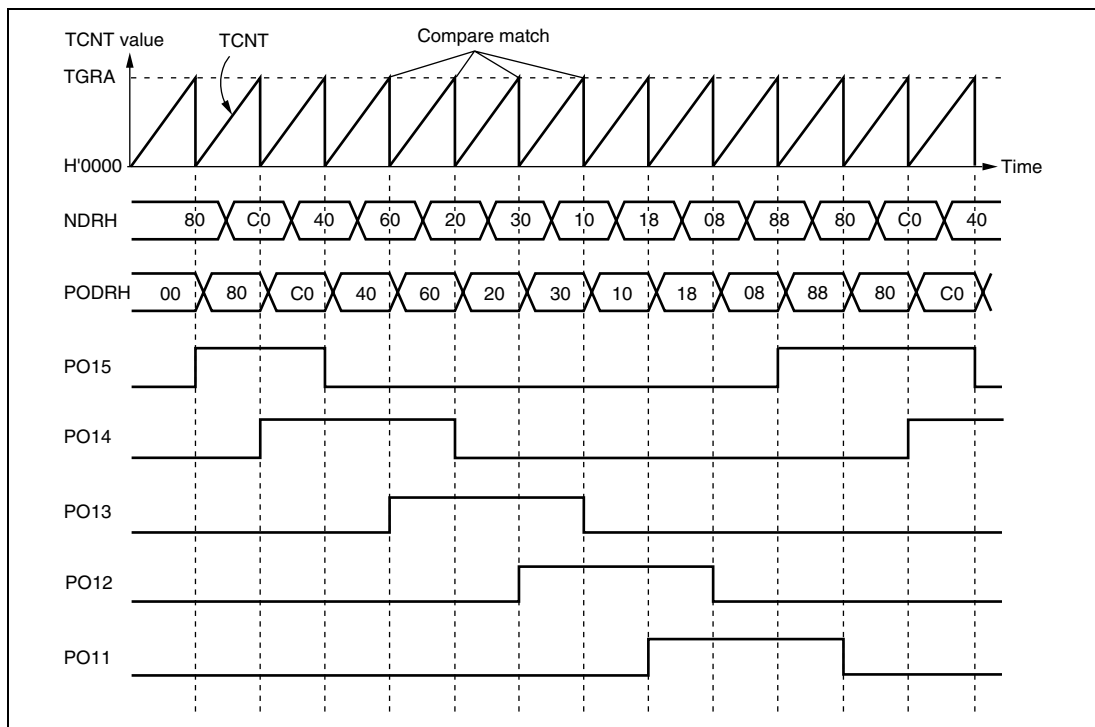

Figure 11.5 Normal Pulse Output Example (Five-Phase Pulse Output)

1. Set up TGRA in TPU which is used as the output trigger to be an output compare register. Set a cycle in TGRA so the counter will be cleared by compare match A. Set the TGIEA bit in TIER to 1 to enable the compare match/input capture A (TGIA) interrupt.
2. Write H'F8 in P1DDR and NDERH, and set the G3CMS1, G3CMS0, G2CMS1, and G2CMS0 bits in PCR to select compare match in the TPU channel set up in the previous step to be the output trigger. Write output data H'80 in NDRH.
3. The timer counter in the TPU channel starts. When compare match A occurs, the NDRH contents are transferred to PODRH and output. The TGIA interrupt handling routine writes the next output data (H'C0) in NDRH.
4. Five-phase pulse output (one or two phases active at a time) can be obtained subsequently by writing H'40, H'60, H'20, H'30, H'10, H'18, H'08, H'88... at successive TGIA interrupts.
If the DTC or DMAC is set for activation by the TGIA interrupt, pulse output can be obtained without imposing a load on the CPU.

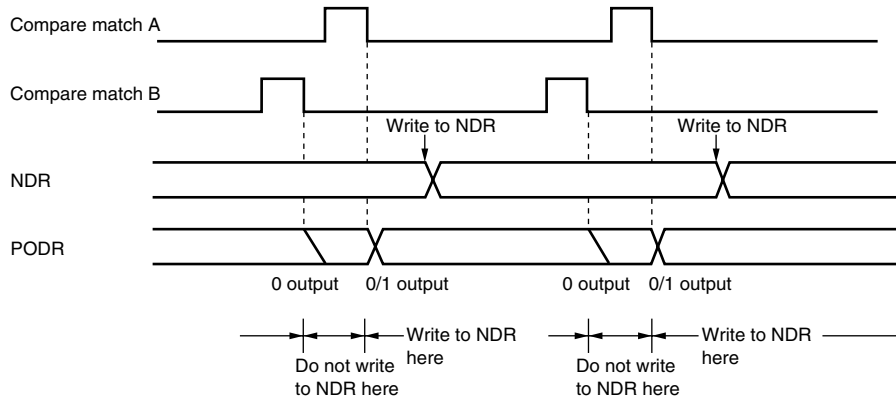

Figure 11.7 Non-Overlapping Operation and NDR Write Timing

11.4.5 Sample Setup Procedure for Non-Overlapping Pulse Output

Figure 11.8 shows a sample procedure for setting up non-overlapping pulse output.

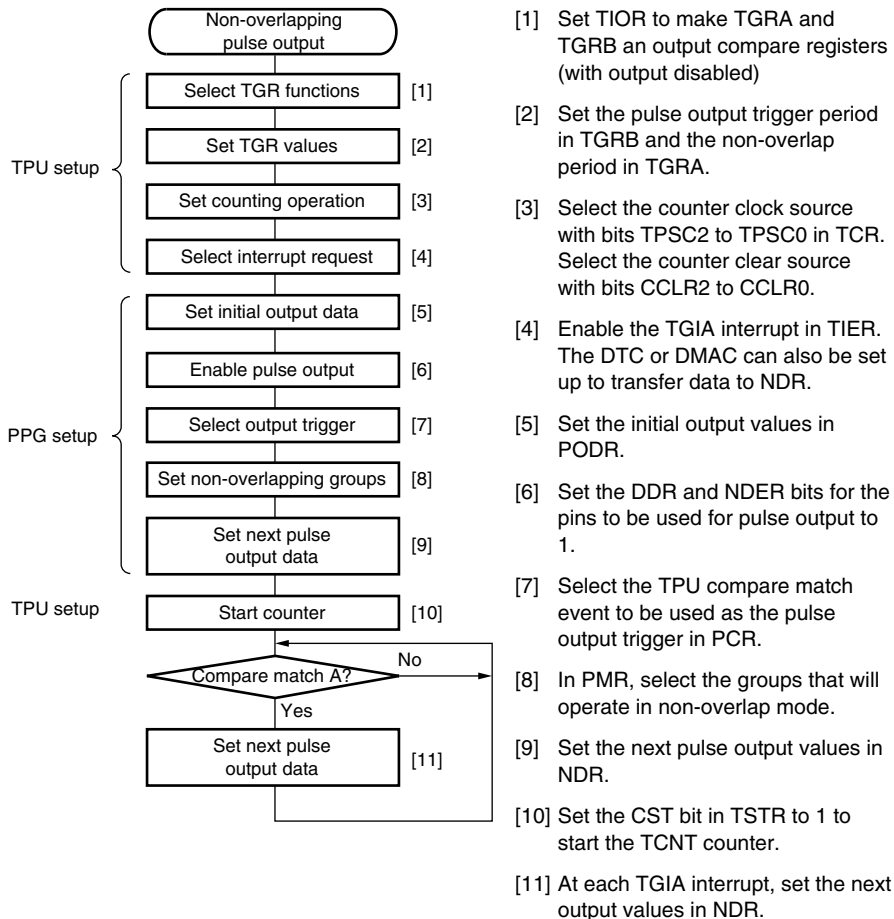

Figure 11.8 Setup Procedure for Non-Overlapping Pulse Output (Example)

11.4.6 Example of Non-Overlapping Pulse Output (Example of Four-Phase Complementary Non-Overlapping Output)

Figure 11.9 shows an example in which pulse output is used for four-phase complementary non-overlapping pulse output.

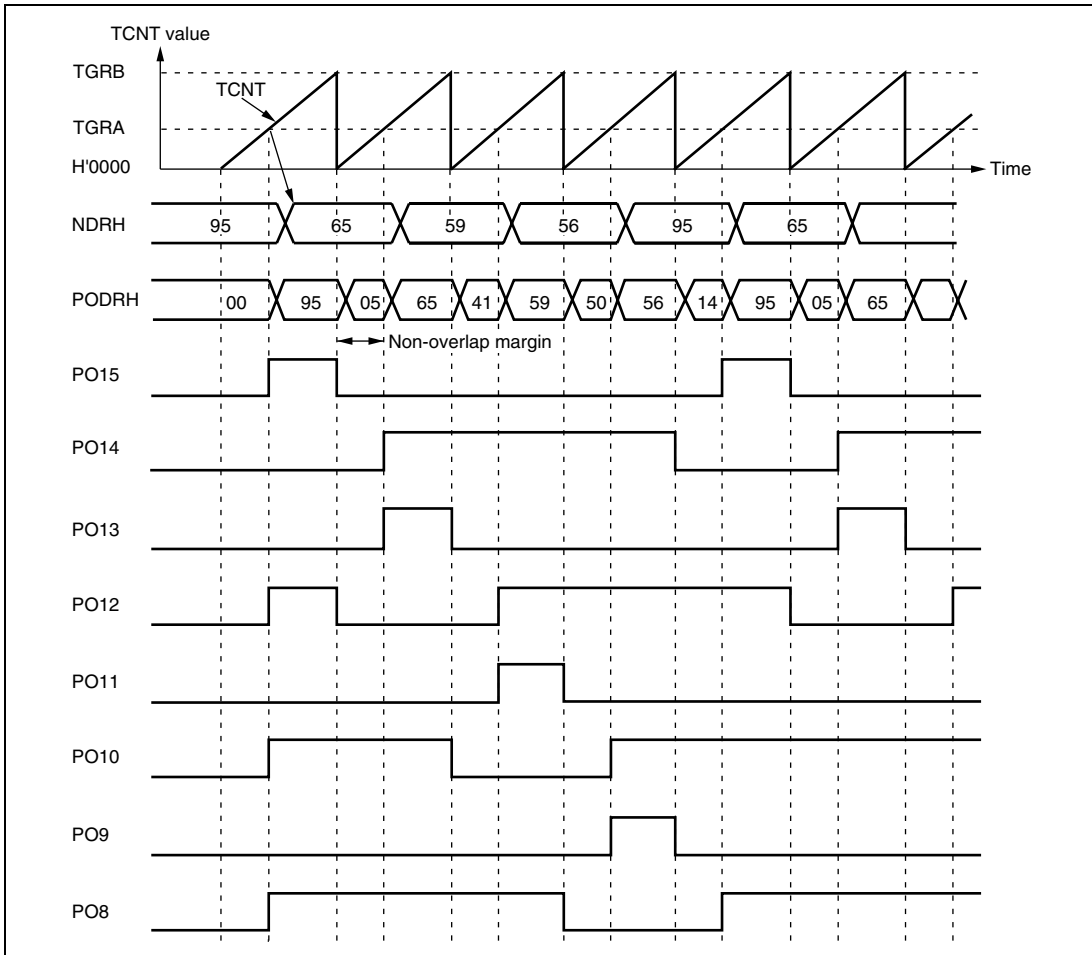

Figure 11.9 Non-Overlapping Pulse Output Example (Four-Phase Complementary)

1. Set up the TPU channel to be used as the output trigger channel so that TGRA and TGRB are output compare registers. Set the trigger period in TGRB and the non-overlap margin in TGRA, and set the counter to be cleared by compare match B. Set the TGIEA bit in TIER to 1 to enable the TGIA interrupt.
2. Write H'FF in P1DDR and NDERH, and set the G3CMS1, G3CMS0, G2CMS1, and G2CMS0 bits in PCR to select compare match in the TPU channel set up in the previous step to be the output trigger. Set the G3NOV and G2NOV bits in PMR to 1 to select non-overlapping output. Write output data H'95 in NDRH.
3. The timer counter in the TPU channel starts. When a compare match with TGRB occurs, outputs change from 1 to 0. When a compare match with TGRA occurs, outputs change from 0 to 1 (the change from 0 to 1 is delayed by the value set in TGRA). The TGIA interrupt handling routine writes the next output data (H'65) in NDRH.

4. Four-phase complementary non-overlapping pulse output can be obtained subsequently by writing H'59, H'56, H'95... at successive TGIA interrupts.

If the DTC or DMAC is set for activation by the TGIA interrupt, pulse output can be obtained without imposing a load on the CPU.

11.4.7 Inverted Pulse Output

If the G3INV, G2INV, G1INV, and G0INV bits in PMR are cleared to 0, values that are the inverse of the PODR contents can be output.

Figure 11.10 shows the outputs when G3INV and G2INV are cleared to 0, in addition to the settings of figure 11.9.

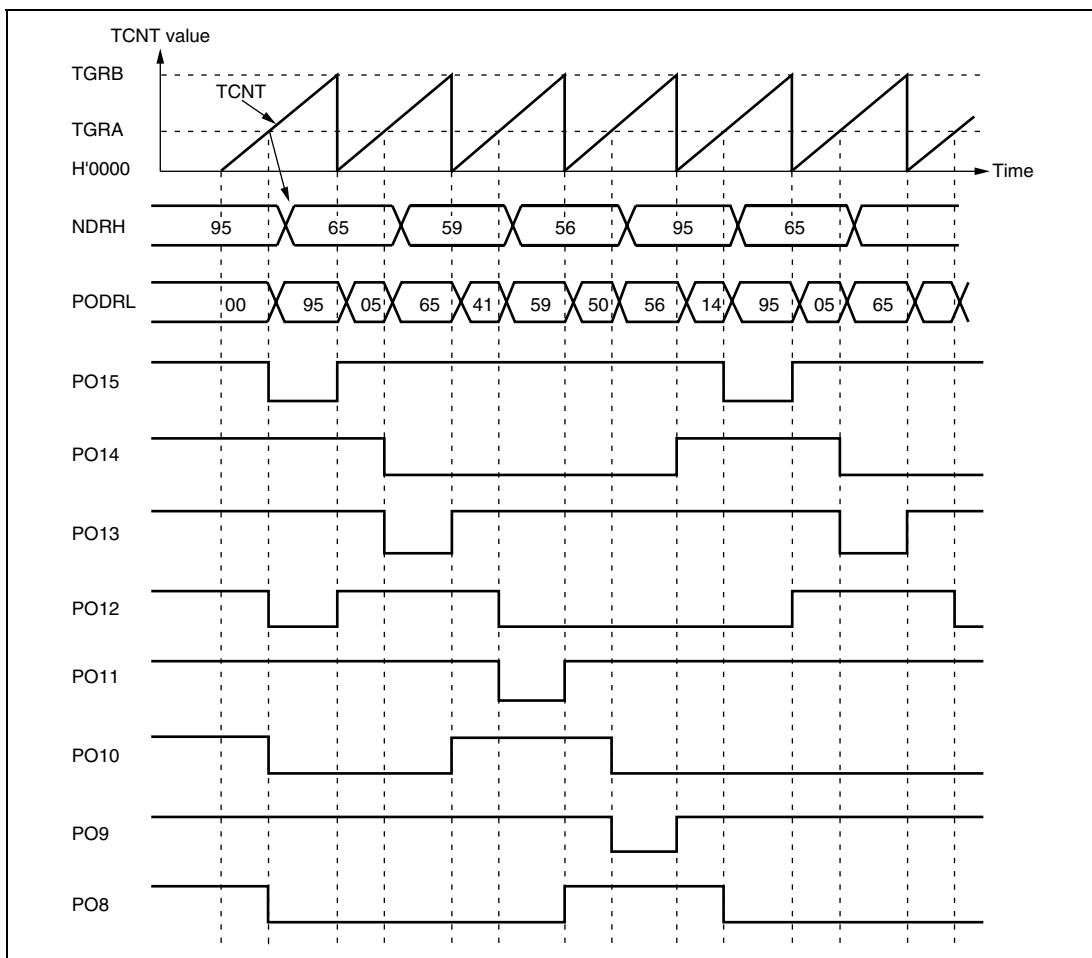

Figure 11.10 Inverted Pulse Output (Example)

11.4.8 Pulse Output Triggered by Input Capture

Pulse output can be triggered by TPU input capture as well as by compare match. If TGRA functions as an input capture register in the TPU channel selected by PCR, pulse output will be triggered by the input capture signal.

Figure 11.11 shows the timing of this output.

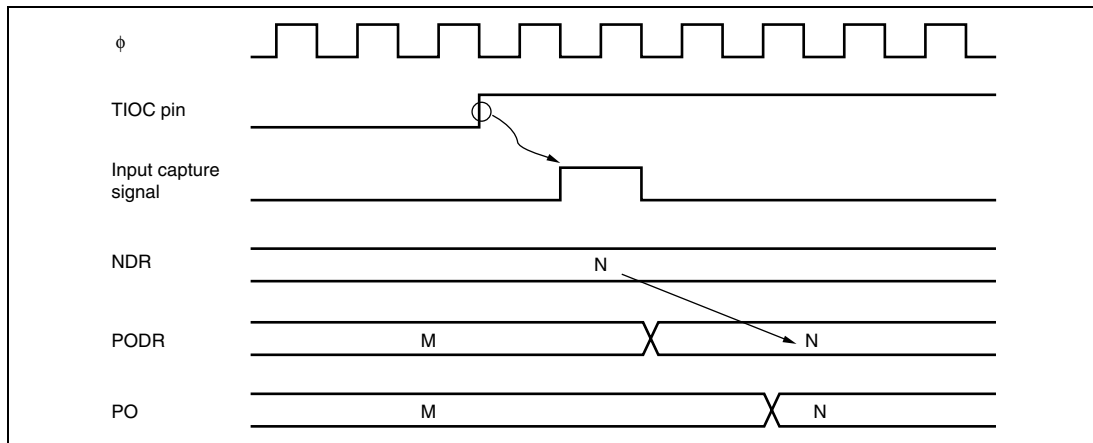

Figure 11.11 Pulse Output Triggered by Input Capture (Example)

11.5 Usage Notes

11.5.1 Module Stop Mode Setting

PPG operation can be disabled or enabled using the module stop control register. The initial value is for PPG operation to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 22, Power-Down Modes.

11.5.2 Operation of Pulse Output Pins

Pins PO0 to PO15 are also used for other peripheral functions such as the TPU. When output by another peripheral function is enabled, the corresponding pins cannot be used for pulse output. Note, however, that data transfer from NDR bits to PODR bits takes place, regardless of the usage of the pins.

Pin functions should be changed only under conditions in which the output trigger event will not occur.

Section 12 8-Bit Timers (TMR)

This LSI has an on-chip 8-bit timer module with two channels operating on the basis of an 8-bit counter. The 8-bit timer module can be used to count external events and be used as a multifunction timer in a variety of applications, such as generation of counter reset, interrupt requests, and pulse output with an arbitrary duty cycle using a compare-match signal with two registers.

12.1 Features

- Selection of four clock sources
The counters can be driven by one of three internal clock signals ($\phi/8$, $\phi/64$, or $\phi/8192$) or an external clock input
- Selection of three ways to clear the counters
The counters can be cleared on compare match A or B, or by an external reset signal
- Timer output control by a combination of two compare match signals
The timer output signal in each channel is controlled by a combination of two independent compare match signals, enabling the timer to generate output waveforms with an arbitrary duty cycle or PWM output
- Provision for cascading of two channels (TMR_0 and TMR_1)
Operation as a 16-bit timer is possible, using TMR_0 for the upper 8 bits and TMR_1 for the lower 8 bits (16-bit count mode)
TMR_1 can be used to count TMR_0 compare matches (compare match count mode)
- Three independent interrupts
Compare match A and B and overflow interrupts can be requested independently
- A/D converter conversion start trigger can be generated

Figure 12.1 shows a block diagram of the 8-bit timer module (TMR_0 and TMR_1).

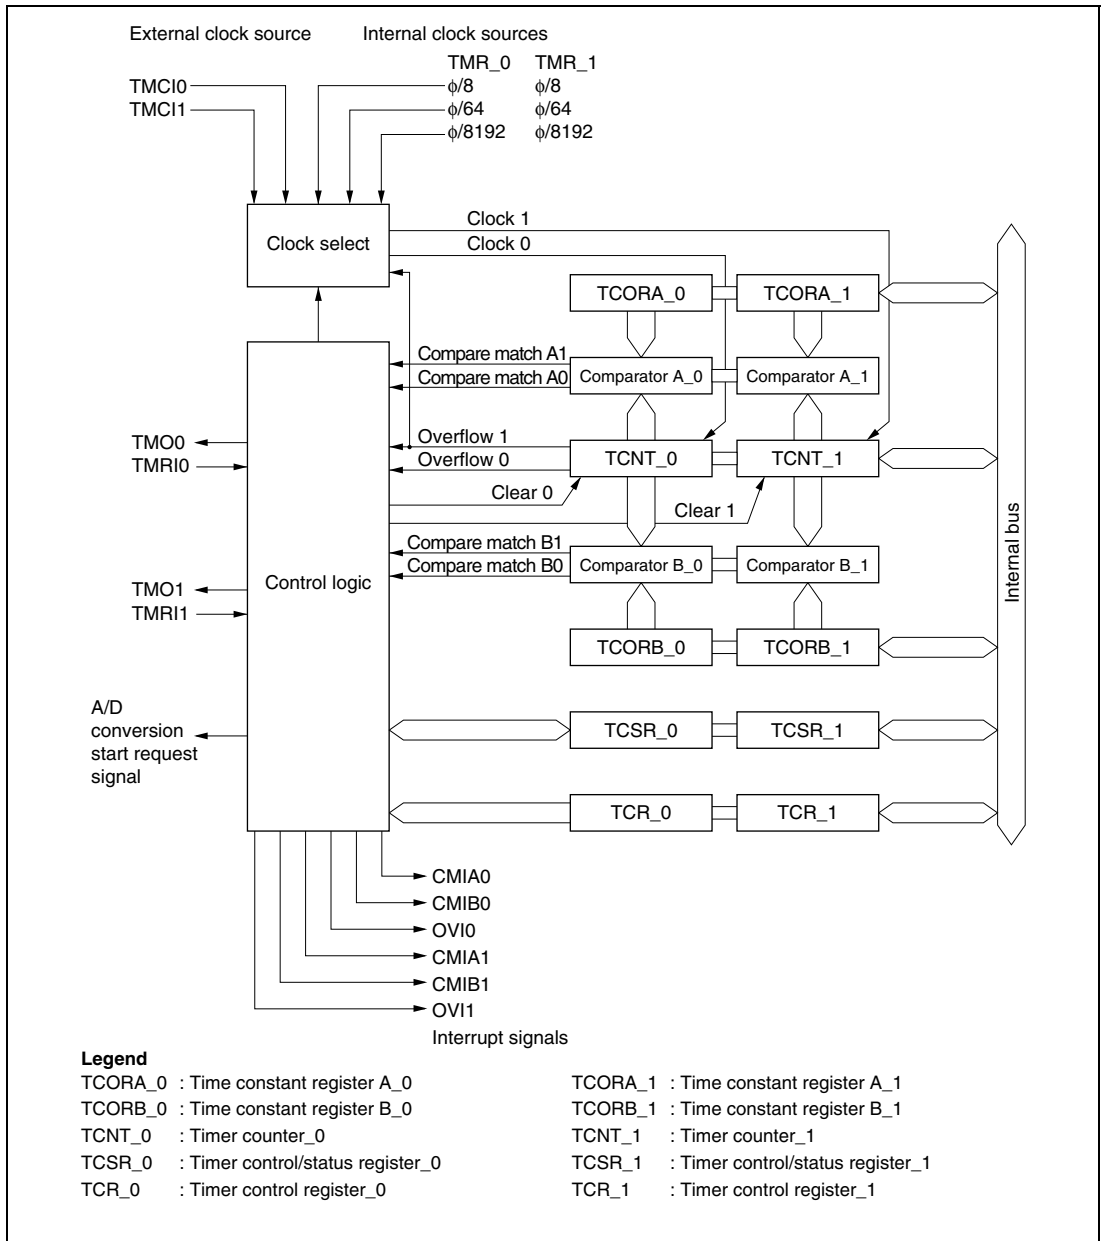

Figure 12.1 Block Diagram of 8-Bit Timer Module

12.2 Input/Output Pins

Table 12.1 summarizes the pins of the 8-bit timer module.

Table 12.1 Pin Configuration

Channel	Name	Symbol	I/O	Function
0	Timer output pin	TMO0	Output	Outputs at compare match
	Timer clock input pin	TMCi0	Input	Inputs external clock for counter
	Timer reset input pin	TMRi0	Input	Inputs external reset to counter
1	Timer output pin	TMO1	Output	Outputs at compare match
	Timer clock input pin	TMCi1	Input	Inputs external clock for counter
	Timer reset input pin	TMRi1	Input	Inputs external reset to counter

12.3 Register Descriptions

The 8-bit timer module has the following registers. For details on the module stop control register, refer to section 22.1.2, Module Stop Control Registers H, L (MSTPCRH, MSTPCRL).

- Timer counter_0 (TCNT_0)
- Time constant register A_0 (TCORA_0)
- Time constant register B_0 (TCORB_0)
- Timer control register_0 (TCR_0)
- Timer control/status register_0 (TCSR_0)
- Timer counter_1 (TCNT_1)
- Time constant register A_1 (TCORA_1)
- Time constant register B_1 (TCORB_1)
- Timer control register_1 (TCR_1)
- Timer control/status register_1 (TCSR_1)

12.3.1 Timer Counter (TCNT)

TCNT is 8-bit up-counter. TCNT_0 and TCNT_1 comprise a single 16-bit register so they can be accessed together by a word transfer instruction. Bits CKS2 to CKS0 in TCR are used to select a clock. TCNT can be cleared by an external reset input or by a compare match signal A or B. Which signal is to be used for clearing is selected by bits CCLR1 and CCLR0 in TCR. When TCNT overflows from H'FF to H'00, OVF in TCSR is set to 1. TCNT is initialized to H'00.

12.3.2 Time Constant Register A (TCORA)

TCORA is 8-bit readable/writable register. TCORA_0 and TCORA_1 comprise a single 16-bit register so they can be accessed together by a word transfer instruction.

The value in TCORA is continually compared with the value in TCNT. When a match is detected, the corresponding CMFA flag in TCSR is set to 1. Note, however, that comparison is disabled during the T_2 state of a TCORA write cycle.

The timer output from the TMO pin can be freely controlled by this compare match signal (compare match A) and the settings of bits OS1 and OS0 in TCSR.

TCORA is initialized to H'FF.

12.3.3 Time Constant Register B (TCORB)

TCORB is 8-bit readable/writable register. TCORB_0 and TCORB_1 comprise a single 16-bit register so they can be accessed together by a word transfer instruction.

TCORB is continually compared with the value in TCNT. When a match is detected, the corresponding CMFB flag in TCSR is set to 1. Note, however, that comparison is disabled during the T_2 state of a TCOBR write cycle.

The timer output from the TMO pin can be freely controlled by this compare match signal (compare match B) and the settings of bits OS3 and OS2 in TCSR.

TCORB is initialized to H'FF.

12.3.4 Timer Control Register (TCR)

TCR selects the clock source and the time at which TCNT is cleared, and controls interrupts.

Bit	Bit Name	Initial Value	R/W	Description
7	CMIEB	0	R/W	<p>Compare Match Interrupt Enable B</p> <p>Selects whether CMFB interrupt requests (CMIB) are enabled or disabled when the CMFB flag in TCSR is set to 1.</p> <p>0: CMFB interrupt requests (CMIB) are disabled</p> <p>1: CMFB interrupt requests (CMIB) are enabled</p>
6	CMIEA	0	R/W	<p>Compare Match Interrupt Enable A</p> <p>Selects whether CMFA interrupt requests (CMIA) are enabled or disabled when the CMFA flag in TCSR is set to 1.</p> <p>0: CMFA interrupt requests (CMIA) are disabled</p> <p>1: CMFA interrupt requests (CMIA) are enabled</p>
5	OVIE	0	R/W	<p>Timer Overflow Interrupt Enable</p> <p>Selects whether OVF interrupt requests (OVI) are enabled or disabled when the OVF flag in TCSR is set to 1.</p> <p>0: OVF interrupt requests (OVI) are disabled</p> <p>1: OVF interrupt requests (OVI) are enabled</p>
4	CCLR1	0	R/W	<p>Counter Clear 1 and 0</p> <p>These bits select the method by which TCNT is cleared</p> <p>00: Clearing is disabled</p> <p>01: Clear by compare match A</p> <p>10: Clear by compare match B</p> <p>11: Clear by rising edge of external reset input</p>
3	CCLR0	0	R/W	
2	CKS2	0	R/W	Clock Select 2 to 0
1	CKS1	0	R/W	These bits select the clock input to TCNT and count condition. See table 12.2.
0	CKS0	0	R/W	

Table 12.2 Clock Input to TCNT and Count Condition

Channel	TCR			Description
	Bit 2 CKS2	Bit 1 CKS1	Bit 0 CKS0	
TMR_0	0	0	0	Clock input disabled
			1	Internal clock, counted at falling edge of $\phi/8$
		1	0	Internal clock, counted at falling edge of $\phi/64$
			1	Internal clock, counted at falling edge of $\phi/8192$
	1	0	0	Count at TCNT_1 overflow signal*
TMR_1	0	0	0	Clock input disabled
			1	Internal clock, counted at falling edge of $\phi/8$
		1	0	Internal clock, counted at falling edge of $\phi/64$
			1	Internal clock, counted at falling edge of $\phi/8192$
	1	0	0	Count at TCNT_0 compare match A*
All	1	0	1	External clock, counted at rising edge
		1	0	External clock, counted at falling edge
		1	1	External clock, counted at both rising and falling edges

Note: * If the count input of TMR_0 is the TCNT_1 overflow signal and that of TMR_1 is the TCNT_0 compare match signal, no incrementing clock is generated. Do not use this setting.

12.3.5 Timer Control/Status Register (TCSR)

TCSR displays status flags, and controls compare match output.

TCSR_0

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
4	—	1	R	Reserved This bit is always read as 1 and cannot be modified.
3	OS3	0	R/W	Output Select 3 and 2
2	OS2	0	R/W	These bits select a method of TMO pin output when compare match B of TCORB and TCNT occurs. 00: No change when compare match B occurs 01: 0 is output when compare match B occurs 10: 1 is output when compare match B occurs 11: Output is inverted when compare match B occurs (toggle output)
1	OS1	0	R/W	Output Select 1 and 0
0	OS0	0	R/W	These bits select a method of TMO pin output when compare match A of TCORA and TCNT occurs. 00: No change when compare match A occurs 01: 0 is output when compare match A occurs 10: 1 is output when compare match A occurs 11: Output is inverted when compare match A occurs (toggle output)

Note: * Only 0 can be written to bits 7 to 5, to clear these flags.

12.4 Operation

12.4.1 Pulse Output

Figure 12.2 shows an example that the 8-bit timer is used to generate a pulse output with a selected duty cycle. The control bits are set as follows:

- [1] In TCR, bit CCLR1 is cleared to 0 and bit CCLR0 is set to 1 so that the timer counter is cleared at a TCORA compare match.
- [2] In TCSR, bits OS3 to OS0 are set to B'0110, causing the output to change to 1 at a TCORA compare match and to 0 at a TCORB compare match.

With these settings, the 8-bit timer provides output of pulses at a rate determined by TCORA with a pulse width determined by TCORB. No software intervention is required.

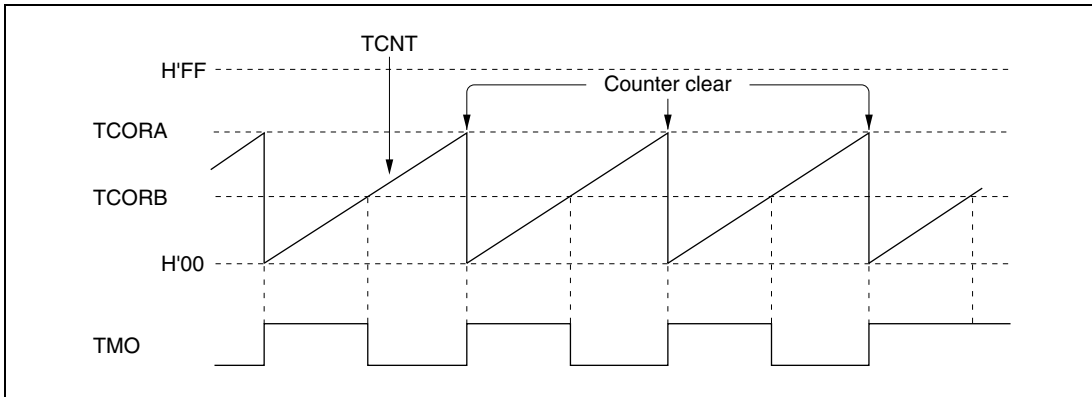

Figure 12.2 Example of Pulse Output

12.5 Operation Timing

12.5.1 TCNT Incrementation Timing

Figure 12.3 shows the count timing for internal clock input. Figure 12.4 shows the count timing for external clock signal. Note that the external clock pulse width must be at least 1.5 states for incrementation at a single edge, and at least 2.5 states for incrementation at both edges. The counter will not increment correctly if the pulse width is less than these values.

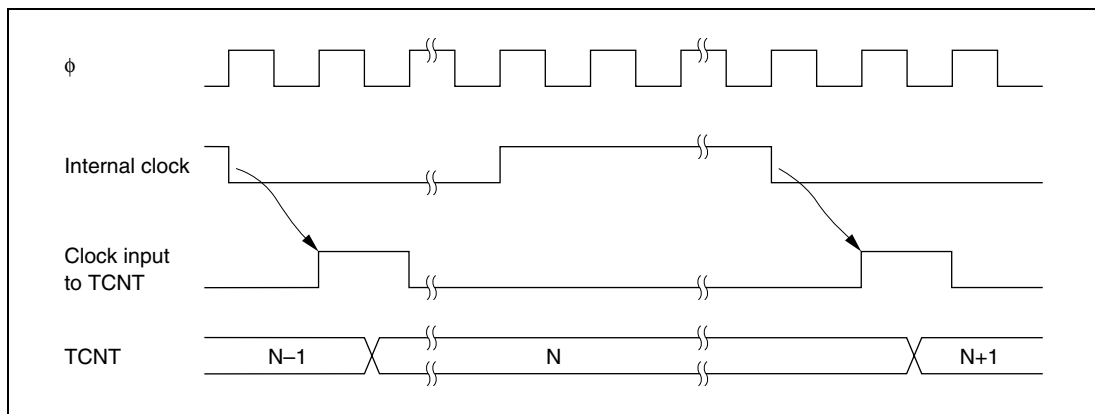

Figure 12.3 Count Timing for Internal Clock Input

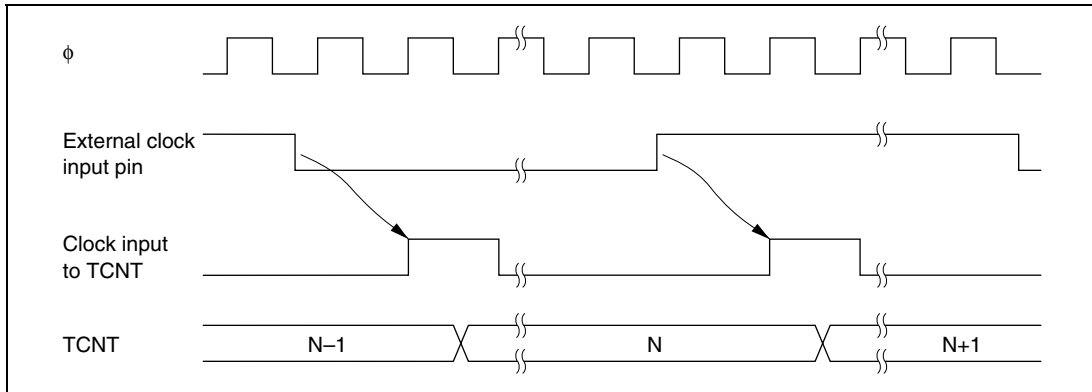

Figure 12.4 Count Timing for External Clock Input

12.5.2 Timing of CMFA and CMFB Setting when Compare-Match Occurs

The CMFA and CMFB flags in TCSR are set to 1 by a compare match signal generated when the TCOR and TCNT values match. The compare match signal is generated at the last state in which the match is true, just before the timer counter is updated. Therefore, when TCOR and TCNT match, the compare match signal is not generated until the next incrementation clock input. Figure 12.5 shows this timing.

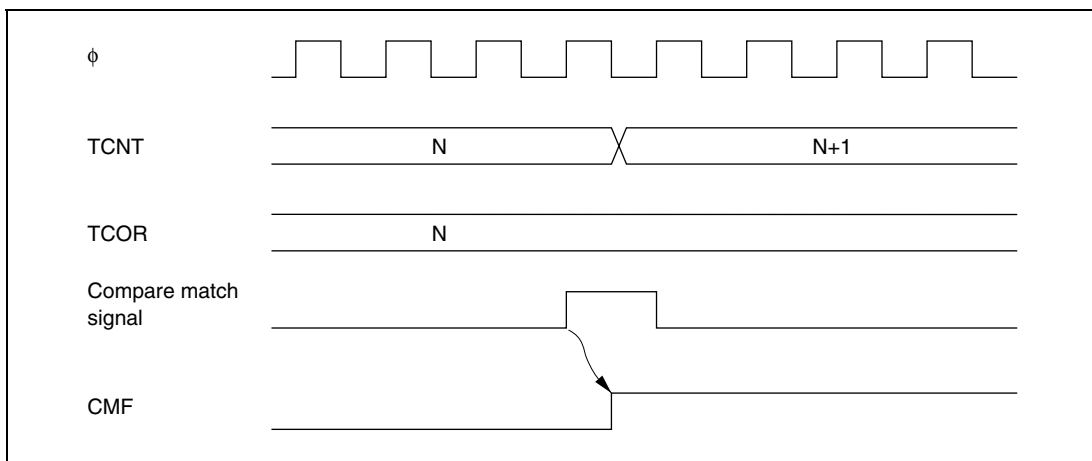

Figure 12.5 Timing of CMF Setting

12.5.3 Timing of Timer Output when Compare-Match Occurs

When compare match A or B occurs, the timer output changes as specified by bits OS3 to OS0 in TCSR.

Figure 12.6 shows the timing when the output is set to toggle at compare match A.

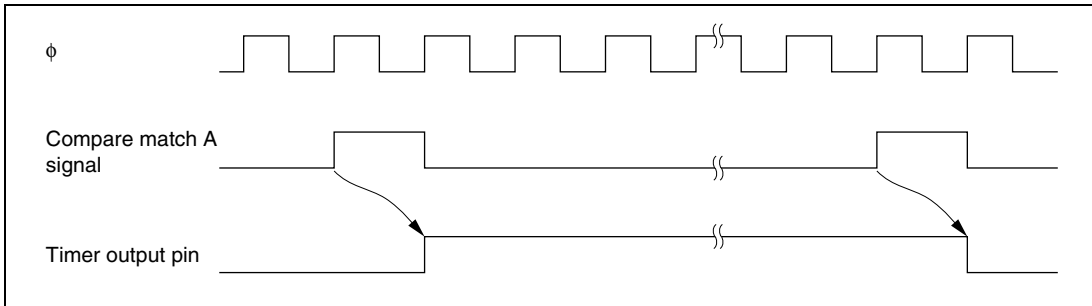

Figure 12.6 Timing of Timer Output

12.5.4 Timing of Compare Match Clear

TCNT is cleared when compare match A or B occurs, depending on the setting of the CCLR1 and CCLR0 bits in TCR. Figure 12.7 shows the timing of this operation.

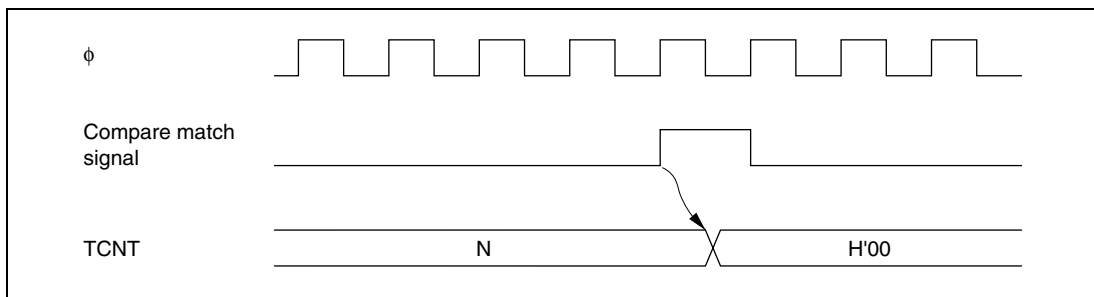

Figure 12.7 Timing of Compare Match Clear

12.5.5 Timing of TCNT External Reset

TCNT is cleared at the rising edge of an external reset input, depending on the settings of the CCLR1 and CCLR0 bits in TCR. The clear pulse width must be at least 1.5 states. Figure 12.8 shows the timing of this operation.

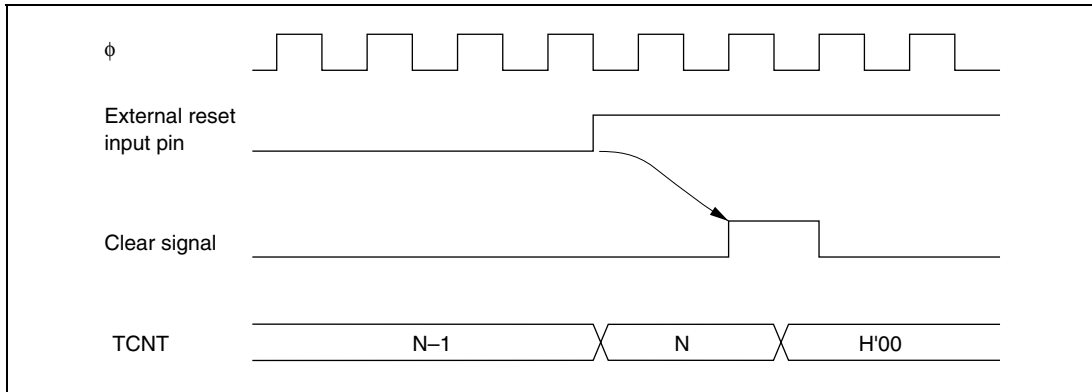

Figure 12.8 Timing of Clearance by External Reset

12.5.6 Timing of Overflow Flag (OVF) Setting

The OVF in TCSR is set to 1 when TCNT overflows (changes from H'FF to H'00). Figure 12.9 shows the timing of this operation.

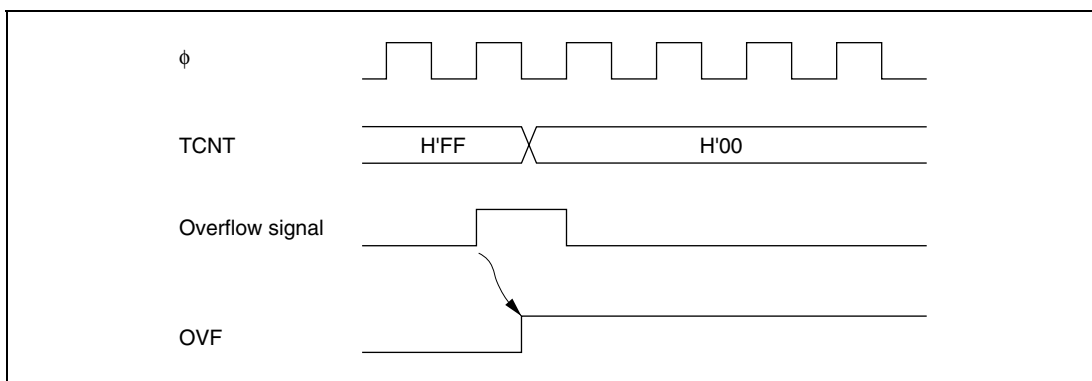

Figure 12.9 Timing of OVF Setting

12.6 Operation with Cascaded Connection

If bits CKS2 to CKS0 in either TCR_0 or TCR_1 are set to B'100, the 8-bit timers of the two channels are cascaded. With this configuration, a single 16-bit timer could be used (16-bit counter mode) or compare matches of the 8-bit channel 0 could be counted by the timer of channel 1 (compare match count mode). In this case, the timer operates as below.

12.6.1 16-Bit Counter Mode

When bits CKS2 to CKS0 in TCR_0 are set to B'100, the timer functions as a single 16-bit timer with channel 0 occupying the upper 8 bits and channel 1 occupying the lower 8 bits.

[1] Setting of compare match flags

- The CMF flag in TCSR_0 is set to 1 when a 16-bit compare match event occurs.
- The CMF flag in TCSR_1 is set to 1 when a lower 8-bit compare match event occurs.

[2] Counter clear specification

- If the CCLR1 and CCLR0 bits in TCR_0 have been set for counter clear at compare match, the 16-bit counters (TCNT_0 and TCNT_1 together) are cleared when a 16-bit compare match event occurs. The 16-bit counters (TCNT0 and TCNT1 together) are cleared even if counter clear by the TMRI0 pin has also been set.
- The settings of the CCLR1 and CCLR0 bits in TCR_1 are ignored. The lower 8 bits cannot be cleared independently.

[3] Pin output

- Control of output from the TMO0 pin by bits OS3 to OS0 in TCSR_0 is in accordance with the 16-bit compare match conditions.
- Control of output from the TMO1 pin by bits OS3 to OS0 in TCSR_1 is in accordance with the lower 8-bit compare match conditions.

12.6.2 Compare Match Count Mode

When bits CKS2 to CKS0 in TCR_1 are B'100, TCNT_1 counts compare match A's for channel 0.

Channels 0 and 1 are controlled independently. Conditions such as setting of the CMF flag, generation of interrupts, output from the TMO pin, and counter clear are in accordance with the settings for each channel.

12.7 Interrupts

12.7.1 Interrupt Sources and DTC Activation

There are three 8-bit timer interrupt sources: CMIA, CMIB, and OVI. Their relative priorities are shown in table 12.3. Each interrupt source is set as enabled or disabled by the corresponding interrupt enable bit in TCR or TCSR, and independent interrupt requests are sent for each to the interrupt controller. It is also possible to activate the DTC by means of CMIA and CMIB interrupts.

Table 12.3 8-Bit Timer Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DTC Activation	Priority
CMIA0	TCORA_0 compare match	CMFA	Possible	High
CMIB0	TCORB_0 compare match	CMFB	Possible	↑
OVI0	TCNT_0 overflow	OVF	Not possible	Low
CMIA1	TCORA_1 compare match	CMFA	Possible	High
CMIB1	TCORB_1 compare match	CMFB	Possible	↑
OVI1	TCNT_1 overflow	OVF	Not possible	Low

12.7.2 A/D Converter Activation

The A/D converter can be activated only by TMR_0 compare match A.

If the ADTE bit in TCSR0 is set to 1 when the CMFA flag is set to 1 by the occurrence of TMR_0 compare match A, a request to start A/D conversion is sent to the A/D converter. If the 8-bit timer conversion start trigger has been selected on the A/D converter side at this time, A/D conversion is started.

12.8 Usage Notes

12.8.1 Contention between TCNT Write and Clear

If a timer counter clock pulse is generated during the T_2 state of a TCNT write cycle, the clear takes priority, so that the counter is cleared and the write is not performed.

Figure 12.10 shows this operation.

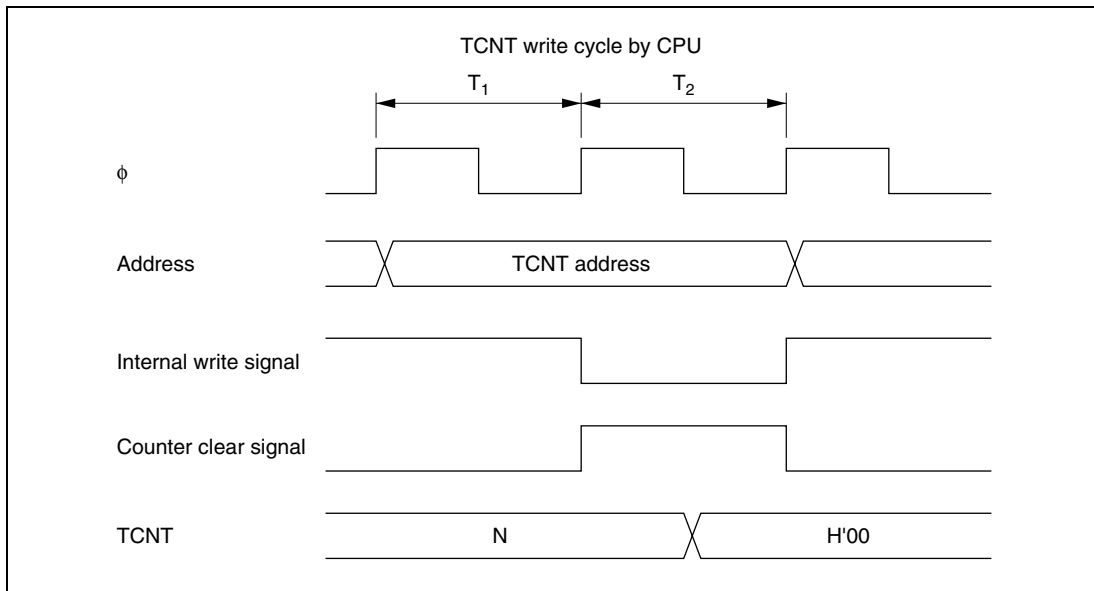

Figure 12.10 Contention between TCNT Write and Clear

12.8.2 Contention between TCNT Write and Increment

If a timer counter clock pulse is generated during the T_2 state of a TCNT write cycle, the write takes priority and the counter is not incremented.

Figure 12.11 shows this operation.

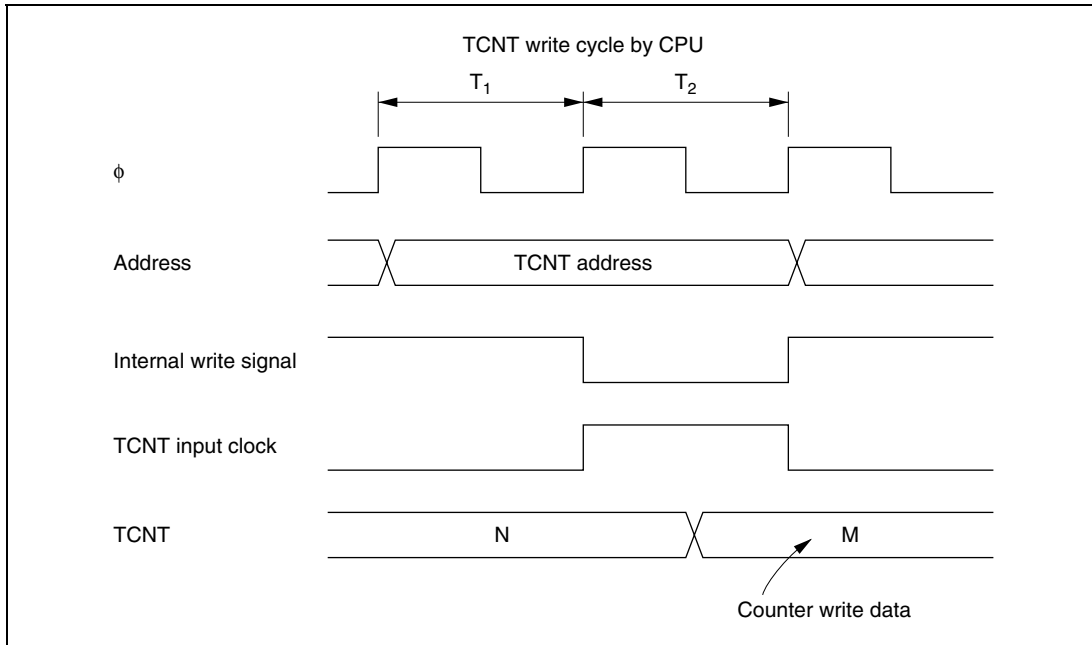

Figure 12.11 Contention between TCNT Write and Increment

12.8.3 Contention between TCOR Write and Compare Match

During the T_2 state of a TCOR write cycle, the TCOR write has priority and the compare match signal is inhibited even if a compare match event occurs as shown in figure 12.12.

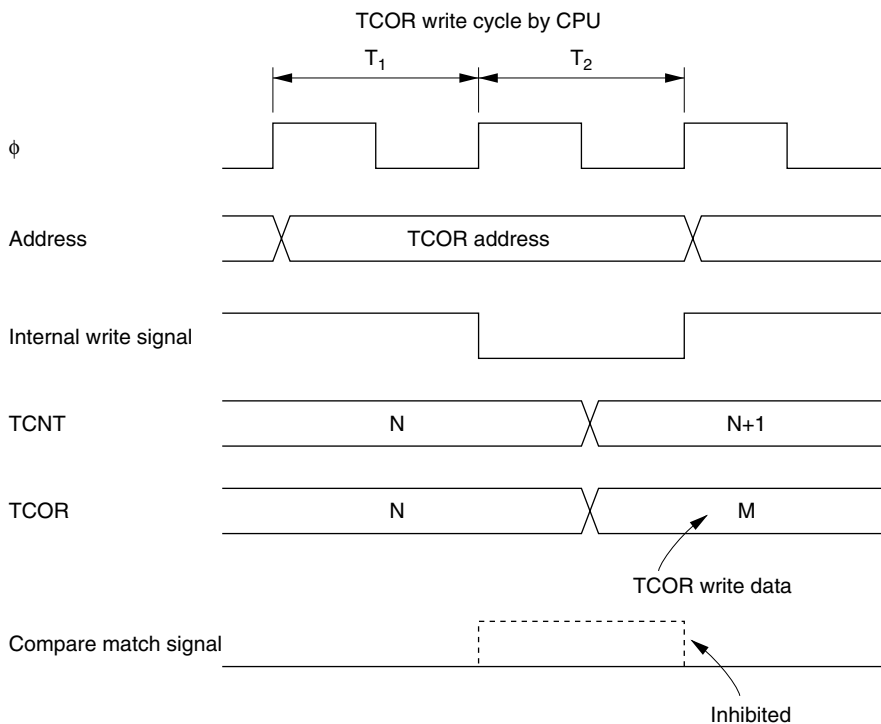

Figure 12.12 Contention between TCOR Write and Compare Match

12.8.4 Contention between Compare Matches A and B

If compare match events A and B occur at the same time, the 8-bit timer operates in accordance with the priorities for the output statuses set for compare match A and compare match B, as shown in table 12.4.

Table 12.4 Timer Output Priorities

Output Setting	Priority
Toggle output	High
1 output	
0 output	
No change	Low

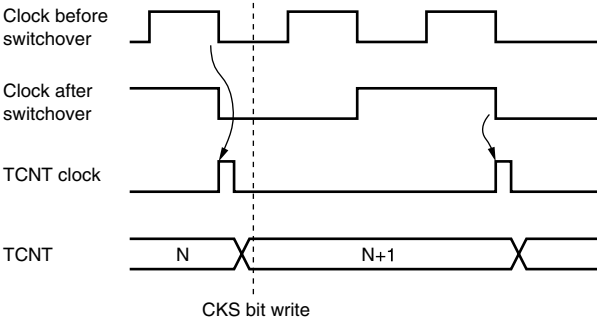

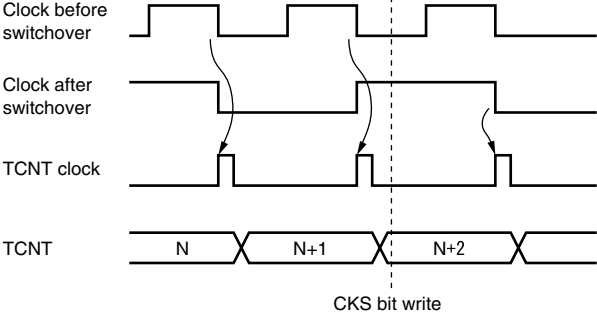

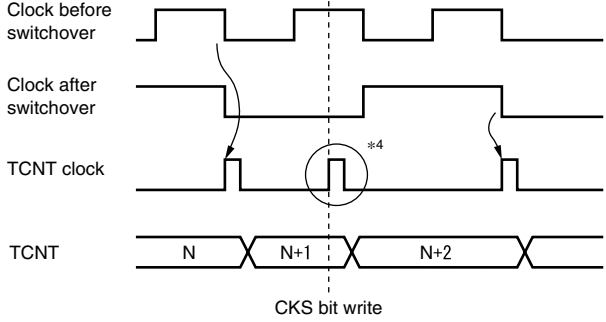

12.8.5 Switching of Internal Clocks and TCNT Operation

TCNT may increment erroneously when the internal clock is switched over. Table 12.5 shows the relationship between the timing at which the internal clock is switched (by writing to the CKS1 and CKS0 bits) and the TCNT operation.

When the TCNT clock is generated from an internal clock, the falling edge of the internal clock pulse is detected. If clock switching causes a change from high to low level, as shown in case 3 in table 12.5, a TCNT clock pulse is generated on the assumption that the switchover is a falling edge. This increments TCNT.

The erroneous incrementation can also happen when switching between internal and external clocks.

Table 12.5 Switching of Internal Clock and TCNT Operation

Timing of Switchover by Means of CKS1 and CKS0 Bits		TCNT Clock Operation	
1	Switching from low to low* ¹		
2	Switching from low to high* ²		
3	Switching from high to low* ³		

No.	Timing of Switchover by Means of CKS1 and CKS0 Bits	TCNT Clock Operation
4	Switching from high to high	<p>CKS bit write</p>

- Notes:
- *1 Includes switching from low to stop, and from stop to low.
 - *2 Includes switching from stop to high.
 - *3 Includes switching from high to stop.
 - *4 Generated on the assumption that the switchover is a falling edge; TCNT is incremented.

12.8.6 Mode Setting with Cascaded Connection

If 16-bit counter mode and compare match count mode are specified at the same time, input clocks for TCNT_0 and TCNT_1 are not generated, and the counter stops. Do not specify 16-bit counter and compare match count modes simultaneously.

12.8.7 Interrupts in Module Stop Mode

If module stop mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DTC and DMAC activation source. Interrupts should therefore be disabled before entering module stop mode.

Section 13 Watchdog Timer

The watchdog timer (WDT) is an 8-bit timer that outputs an overflow signal ($\overline{\text{WDTOVF}}$) if a system crash prevents the CPU from writing to the timer counter, thus allowing it to overflow.

At the same time, the WDT can also generate an internal reset signal.

When this watchdog function is not needed, the WDT can be used as an interval timer. In interval timer operation, an interval timer interrupt is generated each time the counter overflows.

The block diagram of the WDT is shown in figure 13.1.

13.1 Features

- Selectable from eight counter input clocks
- Switchable between watchdog timer mode and interval timer mode

In watchdog timer mode

- If the counter overflows, the WDT outputs $\overline{\text{WDTOVF}}$. It is possible to select whether or not the entire chip is reset at the same time.

In interval timer mode

- If the counter overflows, the WDT generates an interval timer interrupt (WOVI).

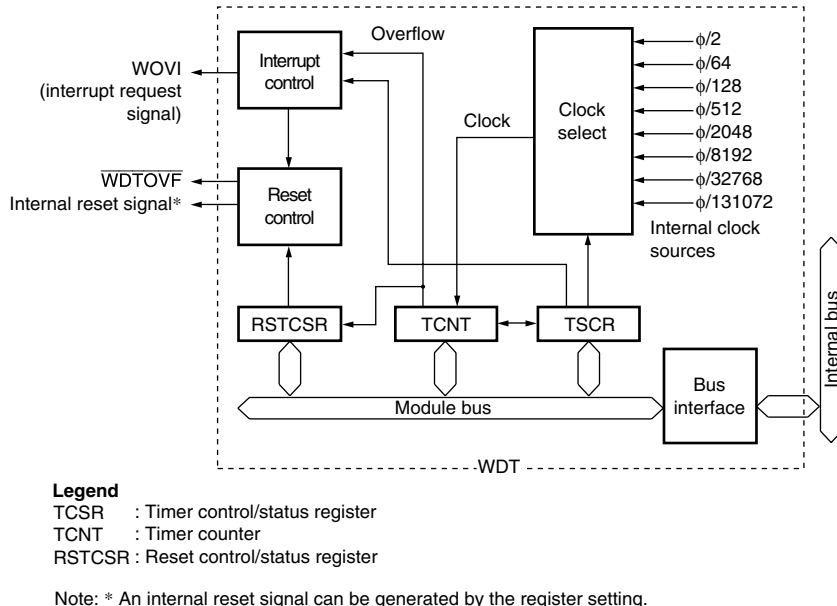

Figure 13.1 Block Diagram of WDT

13.2 Input/Output Pin

Table 13.1 describes the WDT output pin.

Table 13.1 Pin Configuration

Name	Symbol	I/O	Function
Watchdog timer overflow	$\overline{\text{WDTOVF}}$	Output	Outputs counter overflow signal in watchdog timer mode

13.3 Register Descriptions

The WDT has the following three registers. To prevent accidental overwriting, TCSR, TCNT, and RSTCSR have to be written to in a method different from normal registers. For details, refer to section 13.6.1, Notes on Register Access.

- Timer counter (TCNT)
- Timer control/status register (TCSR)
- Reset control/status register (RSTCSR)

13.3.1 Timer Counter (TCNT)

TCNT is an 8-bit readable/writable up-counter. TCNT is initialized to H'00 when the TME bit in TCSR is cleared to 0.

13.3.2 Timer Control/Status Register (TCSR)

TCSR selects the clock source to be input to TCNT, and the timer mode.

Bit	Bit Name	Initial Value	R/W	Description
7	OVF	0	R/(W)*	<p>Overflow Flag</p> <p>Indicates that TCNT has overflowed in interval timer mode. Only a write of 0 is permitted, to clear the flag.</p> <p>[Setting condition]</p> <p>When TCNT overflows in interval timer mode (changes from H'FF to H'00)</p> <p>When internal reset request generation is selected in watchdog timer mode, OVF is cleared automatically by the internal reset.</p> <p>[Clearing condition]</p> <p>Cleared by reading TCSR when OVF = 1, then writing 0 to OVF</p>

Bit	Bit Name	Initial Value	R/W	Description
6	WT/IT	0	R/W	<p>Timer Mode Select</p> <p>Selects whether the WDT is used as a watchdog timer or interval timer.</p> <p>0: Interval timer mode When TCNT overflows, an interval timer interrupt (WOVI) is requested.</p> <p>1: Watchdog timer mode When TCNT overflows, the $\overline{\text{WDTOVF}}$ signal is output.</p>
5	TME	0	R/W	<p>Timer Enable</p> <p>When this bit is set to 1, TCNT starts counting. When this bit is cleared, TCNT stops counting and is initialized to H'00.</p>
4	—	1	—	Reserved
3	—	1	—	These bits are always read as 1 and cannot be modified.
2	CKS2	0	R/W	Clock Select 2 to 0
1	CKS1	0	R/W	<p>Selects the clock source to be input to TCNT. The overflow frequency for $\phi = 20 \text{ MHz}$ is enclosed in parentheses.</p> <p>000: Clock $\phi/2$ (frequency: $25.6 \mu\text{s}$)</p> <p>001: Clock $\phi/64$ (frequency: $819.2 \mu\text{s}$)</p> <p>010: Clock $\phi/128$ (frequency: 1.6 ms)</p> <p>011: Clock $\phi/512$ (frequency: 6.6 ms)</p> <p>100: Clock $\phi/2048$ (frequency: 26.2 ms)</p> <p>101: Clock $\phi/8192$ (frequency: 104.9 ms)</p> <p>110: Clock $\phi/32768$ (frequency: 419.4 ms)</p> <p>111: Clock $\phi/131072$ (frequency: 1.68 s)</p>
0	CKS0	0	R/W	

Note: * Only a write of 0 is permitted, to clear the flag.

13.3.3 Reset Control/Status Register (RSTCSR)

RSTCSR controls the generation of the internal reset signal when TCNT overflows, and selects the type of internal reset signal. RSTCSR is initialized to H'1F by a reset signal from the $\overline{\text{RES}}$ pin, but not by the WDT internal reset signal caused by overflows.

Bit	Bit Name	Initial Value	R/W	Description
7	WOVF	0	R/(W)*	<p>Watchdog Timer Overflow Flag</p> <p>This bit is set when TCNT overflows in watchdog timer mode. This bit cannot be set in interval timer mode, and only 0 can be written.</p> <p>[Setting condition]</p> <p>Set when TCNT overflows (changed from H'FF to H'00) in watchdog timer mode</p> <p>[Clearing condition]</p> <p>Cleared by reading RSTCSR when WOVF = 1, and then writing 0 to WOVF</p>
6	RSTE	0	R/W	<p>Reset Enable</p> <p>Specifies whether or not a reset signal is generated in the chip if TCNT overflows during watchdog timer operation.</p> <p>0: Reset signal is not generated even if TCNT overflows (Though this LSI is not reset, TCNT and TCSR in WDT are reset)</p> <p>1: Reset signal is generated if TCNT overflows</p>
5	—	0	R/W	<p>Reserved</p> <p>These bits can be read from or written to, but the operation is not affected.</p>
4 to 0	—	1	—	<p>Reserved</p> <p>These bits are always read as 1 and cannot be modified.</p>

Note: * Only a write of 0 is permitted, to clear the flag.

13.4 Operation

13.4.1 Watchdog Timer Mode

To use the WDT as a watchdog timer mode, set the $\overline{WT/IT}$ and TME bits in TCSR to 1.

If TCNT overflows without being rewritten because of a system crash or other error, the \overline{WDTOVF} signal is output.

This ensures that TCNT does not overflow while the system is operating normally. Software must prevent TCNT overflows by rewriting the TCNT value (normally by writing H'00) before overflow occurs. This \overline{WDTOVF} signal can be used to reset the chip internally in watchdog timer mode.

If TCNT overflows when 1 is set in the RSTE bit in RSTCSR, a signal that resets this LSI internally is generated at the same time as the \overline{WDTOVF} signal. If a reset caused by a signal input to the \overline{RES} pin occurs at the same time as a reset caused by a WDT overflow, the \overline{RES} pin reset has priority and the WOVF bit in RSTCSR is cleared to 0.

The \overline{WDTOVF} signal is output for 132 states when RSTE = 1, and for 130 states when RSTE = 0. The internal reset signal is output for 518 states.

When TCNT overflows in watchdog timer mode, the WOVF bit in RSTCSR is set to 1. If TCNT overflows when 1 is set in the RSTE bit in RSTCSR, an internal reset signal is generated to the entire chip.

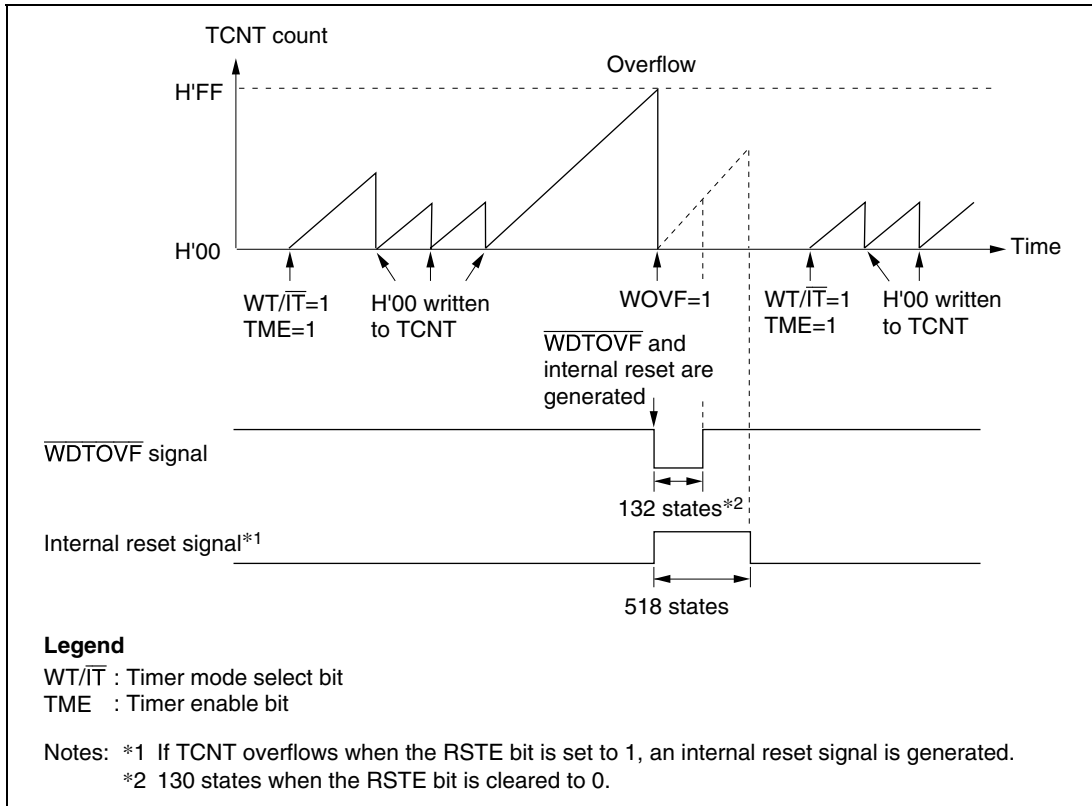

Figure 13.2 Operation in Watchdog Timer Mode

13.4.2 Interval Timer Mode

To use the WDT as an interval timer, set the WT/IT̄ bit to 0 and TME bit in TCSR to 1.

When the WDT is used as an interval timer, an interval timer interrupt (WOVI) is generated each time the TCNT overflows. Therefore, an interrupt can be generated at intervals.

When the TCNT overflows in interval timer mode, an interval timer interrupt (WOVI) is requested at the same time the OVF bit in the TCSR is set to 1.

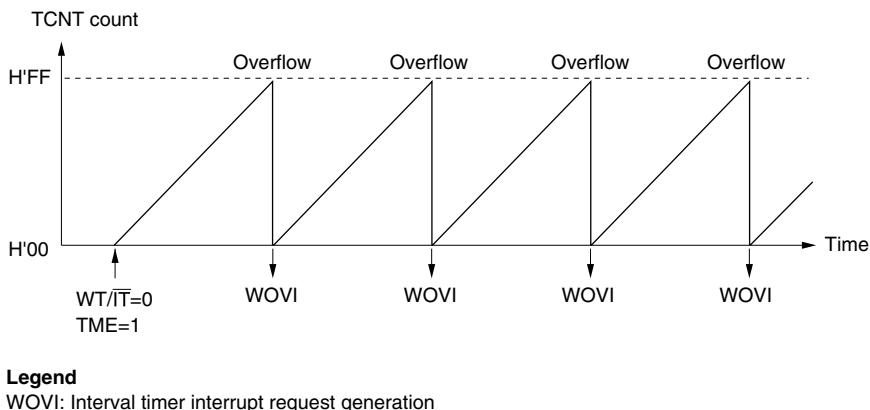

Figure 13.3 Operation in Interval Timer Mode

13.5 Interrupts

During interval timer mode operation, an overflow generates an interval timer interrupt (WOVI). The interval timer interrupt is requested whenever the OVF flag is set to 1 in TCSR. OVF must be cleared to 0 in the interrupt handling routine.

Table 13.2 WDT Interrupt Source

Name	Interrupt Source	Interrupt Flag	DTC Activation
WOVI	TCNT overflow	OVF	Impossible

13.6 Usage Notes

13.6.1 Notes on Register Access

The watchdog timer's TCNT, TCSR, and RSTCSR registers differ from other registers in being more difficult to write to. The procedures for writing to and reading these registers are given below.

Writing to TCNT, TCSR, and RSTCSR

TCNT and TCSR must be written to by a word transfer instruction. They cannot be written to by a byte transfer instruction.

TCNT and TCSR both have the same write address. Therefore, satisfy the relative condition shown in figure 13.4 to write to TCNT or TCSR. The transfer instruction writes the lower byte data to TCNT or TCSR according to the satisfied condition.

To write to RSTCSR, execute a word transfer instruction for address H'FFBE. A byte transfer instruction cannot perform writing to RSTCSR.

The method of writing 0 to the WO VF bit differs from that of writing to the RSTE bit. To write 0 to the WO VF bit, satisfy the lower condition shown in figure 13.4.

If satisfied, the transfer instruction clears the WO VF bit to 0, but has no effect on the RSTE bit. To write to the RSTE bit, satisfy the above condition shown in figure 13.4. If satisfied, the transfer instruction writes the value in bit 6 of the lower byte into the RSTE bit, but has no effect on the WO VF bit.

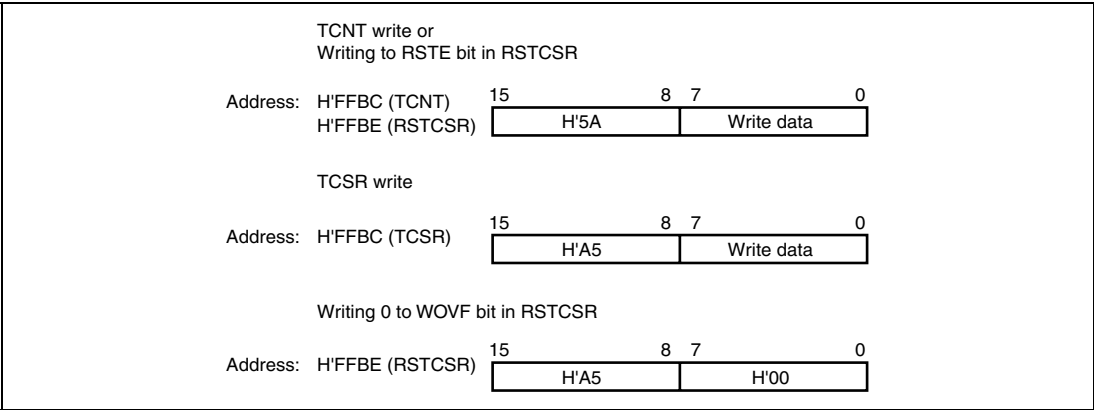

Figure 13.4 Writing to TCNT, TCSR, and RSTCSR

Reading TCNT, TCSR, and RSTCSR

These registers are read in the same way as other registers. The read addresses are H'FFBC for TCSR, H'FFBD for TCNT, and H'FFBF for RSTCSR.

13.6.2 Contention between Timer Counter (TCNT) Write and Increment

If a timer counter clock pulse is generated during the next cycle after the T_2 state of a TCNT write cycle, the write takes priority and the timer counter is not incremented. Figure 13.5 shows this operation.

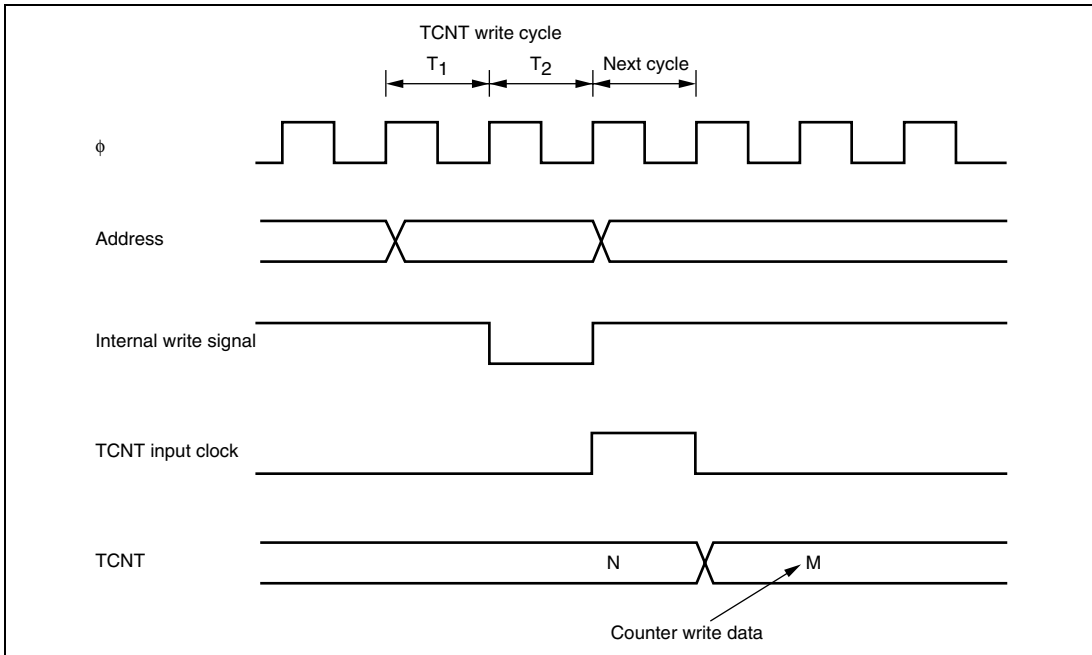

Figure 13.5 Contention between TCNT Write and Increment

13.6.3 Changing Value of CKS2 to CKS0

If bits CKS2 to CKS0 in TCSR are written to while the WDT is operating, errors could occur in the incrementation. Software must stop the watchdog timer (by clearing the TME bit to 0) before changing the value of bits CKS2 to CKS0.

13.6.4 Switching between Watchdog Timer Mode and Interval Timer Mode

If the mode is switched from watchdog timer to interval timer, while the WDT is operating, errors could occur in the incrementation. Software must stop the watchdog timer (by clearing the TME bit to 0) before switching the mode.

13.6.5 Internal Reset in Watchdog Timer Mode

This LSI is not reset internally if TCNT overflows while the RSTE bit is cleared to 0 during watchdog timer mode operation, but TCNT and TCSR of the WDT are reset.

TCNT, TCSR, and RSTCR cannot be written to while the $\overline{\text{WDTOVF}}$ signal is low. Also note that a read of the WOVF flag is not recognized during this period. To clear the WOVF flag, therefore, read TCSR after the $\overline{\text{WDTOVF}}$ signal goes high, then write 0 to the WOVF flag.

13.6.6 System Reset by $\overline{\text{WDTOVF}}$ Signal

If the $\overline{\text{WDTOVF}}$ output signal is input to the $\overline{\text{RES}}$ pin, the chip will not be initialized correctly. Make sure that the $\overline{\text{WDTOVF}}$ signal is not input logically to the $\overline{\text{RES}}$ pin.

To reset the entire system by means of the $\overline{\text{WDTOVF}}$ signal, use the circuit shown in figure 13.6.

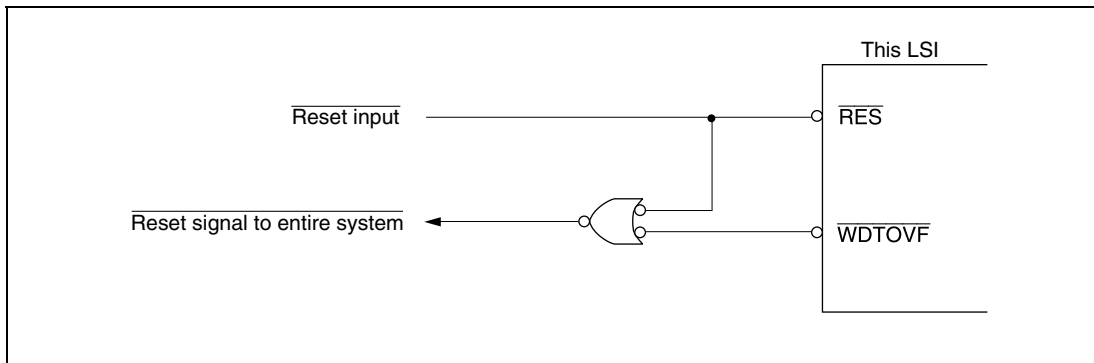

Figure 13.6 Circuit for System Reset by $\overline{\text{WDTOVF}}$ Signal (Example)

Section 14 Serial Communication Interface (SCI, IrDA)

This LSI has five independent serial communication interface (SCI) channels. The SCI can handle both asynchronous and clocked synchronous serial communication. Serial data communication can be carried out with standard asynchronous communication chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). A function is also provided for serial communication between processors (multiprocessor communication function) in asynchronous mode. The SCI also supports an IC card (Smart Card) interface conforming to ISO/IEC 7816-3 (Identification Card) as an asynchronous serial communication interface extension function. One of the five SCI channels (SCI_0) can generate an IrDA communication waveform conforming to IrDA specification version 1.0.

Figure 14.1 shows a block diagram of the SCI.

14.1 Features

- Choice of asynchronous or clocked synchronous serial communication mode
- Full-duplex communication capability
The transmitter and receiver are mutually independent, enabling transmission and reception to be executed simultaneously. Double-buffering is used in both the transmitter and the receiver, enabling continuous transmission and continuous reception of serial data.
- On-chip baud rate generator allows any bit rate to be selected
External clock can be selected as a transfer clock source (except for in Smart Card interface mode).
- Choice of LSB-first or MSB-first transfer (except in the case of asynchronous mode 7-bit data)
- Four interrupt sources
Four interrupt sources — transmit-end, transmit-data-empty, receive-data-full, and receive error — that can issue requests. The transmit-data-empty interrupt and receive data full interrupts can activate the data transfer controller (DTC) or DMA controller (DMAC)*.
- Module stop mode can be set

Note: * Not supported by the H8S/2366.

Asynchronous mode

- Data length: 7 or 8 bits
- Stop bit length: 1 or 2 bits
- Parity: Even, odd, or none
- Receive error detection: Parity, overrun, and framing errors
- Break detection: Break can be detected by reading the RxD pin level directly in case of a framing error
- Average transfer rate generator (SCI_2 only): The following transfer rate can be selected.

115.152 or 460.606 kbps at 10.667 MHz operation
115.196, 460.784 or 720 kbps at 16 MHz operation
720 kbps at 32 MHz operation

Clocked synchronous mode

- Data length: 8 bits
- Receive error detection: Overrun errors detected

Smart Card Interface

- Automatic transmission of error signal (parity error) in receive mode
- Error signal detection and automatic data retransmission in transmit mode
- Direct convention and inverse convention both supported

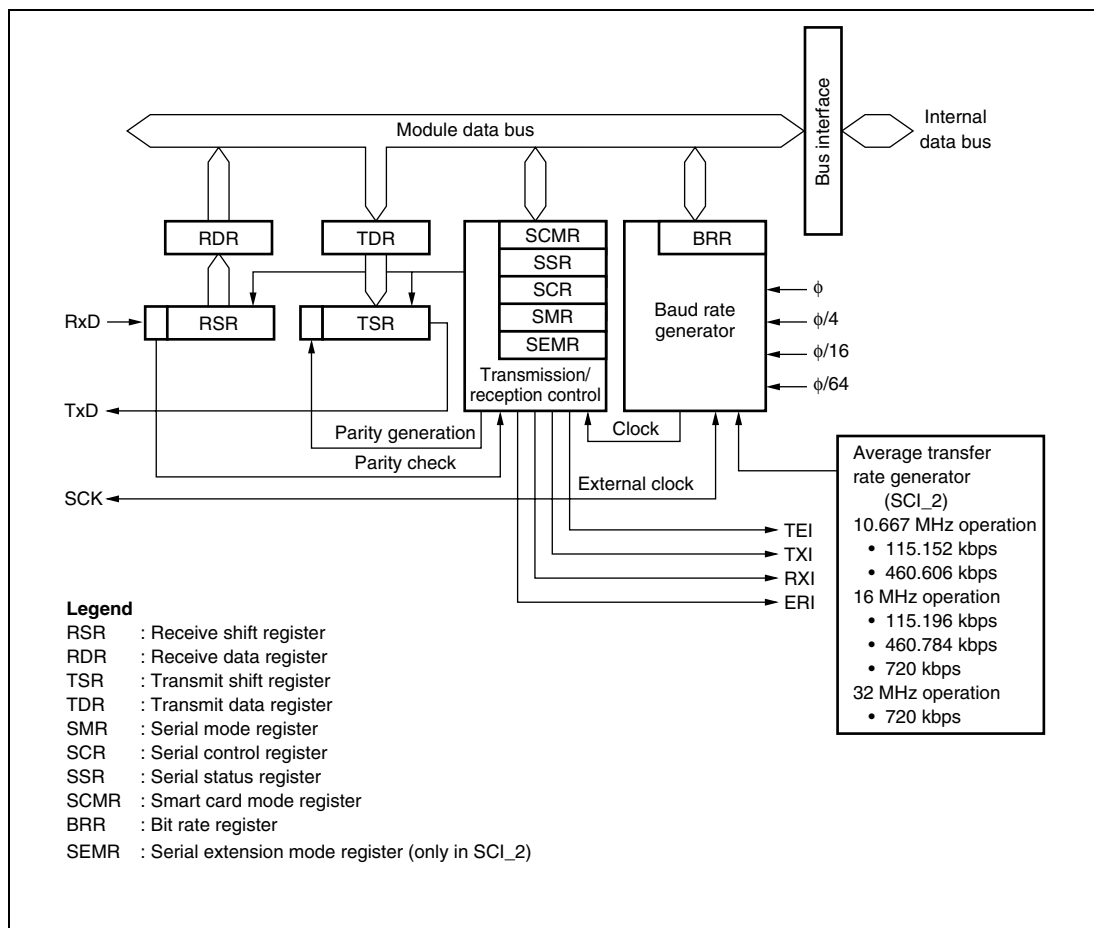

Figure 14.1 Block Diagram of SCI

14.2 Input/Output Pins

Table 14.1 shows the serial pins for each SCI channel.

Table 14.1 Pin Configuration

Channel	Pin Name*	I/O	Function
0	SCK0	I/O	Channel 0 clock input/output
	RxD0/IrRxD	Input	Channel 0 receive data input (normal/IrDA)
	TxD0/IrTxD	Output	Channel 0 transmit data output (normal/IrDA)
1	SCK1	I/O	Channel 1 clock input/output
	RxD1	Input	Channel 1 receive data input
	TxD1	Output	Channel 1 transmit data output
2	SCK2	I/O	Channel 2 clock input/output
	RxD2	Input	Channel 2 receive data input
	TxD2	Output	Channel 2 transmit data output
3	SCK3	I/O	Channel 3 clock input/output
	RxD3	Input	Channel 3 receive data input
	TxD3	Output	Channel 3 transmit data output
4	SCK4	I/O	Channel 4 clock input/output
	RxD4	Input	Channel 4 receive data input
	TxD4	Output	Channel 4 transmit data output

Note: * Pin names SCK, RxD, and TxD are used in the text for all channels, omitting the channel designation.

14.3 Register Descriptions

The SCI has the following registers. The serial mode register (SMR), serial status register (SSR), and serial control register (SCR) are described separately for normal serial communication interface mode and Smart Card interface mode because their bit functions partially differ.

- Receive shift register_0 (RSR_0)
- Transmit shift register_0 (TSR_0)
- Receive data register_0 (RDR_0)
- Transmit data register_0 (TDR_0)
- Serial mode register_0 (SMR_0)
- Serial control register_0 (SCR_0)
- Serial status register_0 (SSR_0)
- Smart card mode register_0 (SCMR_0)
- Bit rate register_0 (BRR_0)
- IrDA control register_0 (IrCR_0)
- Receive shift register_1 (RSR_1)
- Transmit shift register_1 (TSR_1)
- Receive data register_1 (RDR_1)
- Transmit data register_1 (TDR_1)
- Serial mode register_1 (SMR_1)
- Serial control register_1 (SCR_1)
- Serial status register_1 (SSR_1)
- Smart card mode register_1 (SCMR_1)
- Bit rate register_1 (BRR_1)
- Receive shift register_2 (RSR_2)
- Transmit shift register_2 (TSR_2)
- Receive data register_2 (RDR_2)
- Transmit data register_2 (TDR_2)
- Serial mode register_2 (SMR_2)
- Serial control register_2 (SCR_2)
- Serial status register_2 (SSR_2)
- Smart card mode register_2 (SCMR_2)
- Bit rate register_2 (BRR_2)
- Serial extension mode register_2 (SEMR_2)
- Receive shift register_3 (RSR_3)
- Transmit shift register_3 (TSR_3)
- Receive data register_3 (RDR_3)

- Transmit data register_3 (TDR_3)
- Serial mode register_3 (SMR_3)
- Serial control register_3 (SCR_3)
- Serial status register_3 (SSR_3)
- Smart card mode register_3 (SCMR_3)
- Bit rate register_3 (BRR_3)
- Receive shift register_4 (RSR_4)
- Transmit shift register_4 (TSR_4)
- Receive data register_4 (RDR_4)
- Transmit data register_4 (TDR_4)
- Serial mode register_4 (SMR_4)
- Serial control register_4 (SCR_4)
- Serial status register_4 (SSR_4)
- Smart card mode register_4 (SCMR_4)
- Bit rate register_4 (BRR_4)

14.3.1 Receive Shift Register (RSR)

RSR is a shift register used to receive serial data that is input to the RxD pin and convert it into parallel data. When one byte of data has been received, it is transferred to RDR automatically. RSR cannot be directly accessed by the CPU.

14.3.2 Receive Data Register (RDR)

RDR is an 8-bit register that stores receive data. When the SCI has received one byte of serial data, it transfers the received serial data from RSR to RDR where it is stored. After this, RSR is receive-enabled. Since RSR and RDR function as a double buffer in this way, enables continuous receive operations to be performed. After confirming that the RDRF bit in SSR is set to 1, read RDR for only once. RDR cannot be written to by the CPU.

14.3.3 Transmit Data Register (TDR)

TDR is an 8-bit register that stores transmit data. When the SCI detects that TSR is empty, it transfers the transmit data written in TDR to TSR and starts transmission. The double-buffered structures of TDR and TSR enable continuous serial transmission. If the next transmit data has already been written to TDR during serial transmission, the SCI transfers the written data to TSR to continue transmission. Although TDR can be read or written to by the CPU at all times, to achieve reliable serial transmission, write transmit data to TDR for only once after confirming that the TDRE bit in SSR is set to 1.

14.3.4 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first transfers transmit data from TDR to TSR, then sends the data to the TxD pin starting. TSR cannot be directly accessed by the CPU.

14.3.5 Serial Mode Register (SMR)

SMR is used to set the SCI's serial transfer format and select the on-chip baud rate generator clock source.

Some bit functions of SMR differ in normal serial communication interface mode and Smart Card interface mode.

Normal Serial Communication Interface Mode (When SMIF in SCMR is 0)

Bit	Bit Name	Initial Value	R/W	Description
7	C/ \bar{A}	0	R/W	Communication Mode 0: Asynchronous mode 1: Clocked synchronous mode
6	CHR	0	R/W	Character Length (enabled only in asynchronous mode) 0: Selects 8 bits as the data length. 1: Selects 7 bits as the data length. LSB-first is fixed and the MSB (bit 7) of TDR is not transmitted in transmission. In clocked synchronous mode, a fixed data length of 8 bits is used.
5	PE	0	R/W	Parity Enable (enabled only in asynchronous mode) When this bit is set to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. For a multiprocessor format, parity bit addition and checking are not performed regardless of the PE bit setting.
4	O/ \bar{E}	0	R/W	Parity Mode (enabled only when the PE bit is 1 in asynchronous mode) 0: Selects even parity. 1: Selects odd parity.

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	0	R/W	<p>Stop Bit Length (enabled only in asynchronous mode)</p> <p>Selects the stop bit length in transmission.</p> <p>0: 1 stop bit</p> <p>1: 2 stop bits</p> <p>In reception, only the first stop bit is checked regardless of the STOP bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit character.</p>
2	MP	0	R/W	<p>Multiprocessor Mode (enabled only in asynchronous mode)</p> <p>When this bit is set to 1, the multiprocessor communication function is enabled. The PE bit and O/\bar{E} bit settings are invalid in multiprocessor mode.</p>
1	CKS1	0	R/W	<p>Clock Select 1 and 0:</p> <p>These bits select the clock source for the on-chip baud rate generator.</p> <p>00: ϕ clock ($n = 0$)</p> <p>01: $\phi/4$ clock ($n = 1$)</p> <p>10: $\phi/16$ clock ($n = 2$)</p> <p>11: $\phi/64$ clock ($n = 3$)</p> <p>For the relation between the bit rate register setting and the baud rate, see section 14.3.9, Bit Rate Register (BRR). n is the decimal display of the value of n in BRR (see section 14.3.9, Bit Rate Register (BRR)).</p>
0	CKS0	0	R/W	

Bit	Bit Name	Initial Value	R/W	Description
7	GM	0	R/W	<p>GSM Mode</p> <p>When this bit is set to 1, the SCI operates in GSM mode. In GSM mode, the timing of the TEND setting is advanced by 11.0 etu (Elementary Time Unit: the time for transfer of 1 bit), and clock output control mode addition is performed. For details, refer to section 14.7.8, Clock Output Control.</p>
6	BLK	0	R/W	<p>When this bit is set to 1, the SCI operates in block transfer mode. For details on block transfer mode, refer to section 14.7.3, Block Transfer Mode.</p>
5	PE	0	R/W	<p>Parity Enable (enabled only in asynchronous mode)</p> <p>When this bit is set to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. In Smart Card interface mode, this bit must be set to 1.</p>
4	O $\overline{\text{E}}$	0	R/W	<p>Parity Mode (enabled only when the PE bit is 1 in asynchronous mode)</p> <p>0: Selects even parity. 1: Selects odd parity.</p> <p>For details on setting this bit in Smart Card interface mode, refer to section 14.7.2, Data Format (Except for Block Transfer Mode).</p>

Bit	Bit Name	Initial Value	R/W	Description
3	BCP1	0	R/W	Basic Clock Pulse 1 and 0
2	BCP0	0	R/W	<p>These bits select the number of basic clock periods in a 1-bit transfer interval on the Smart Card interface.</p> <p>00: 32 clock (S = 32)</p> <p>01: 64 clock (S = 64)</p> <p>10: 372 clock (S = 372)</p> <p>11: 256 clock (S = 256)</p> <p>For details, refer to section 14.7.4, Receive Data Sampling Timing and Reception Margin. S stands for the value of S in BRR (see section 14.3.9, Bit Rate Register (BRR)).</p>
1	CKS1	0	R/W	Clock Select 1 and 0:
0	CKS0	0	R/W	<p>These bits select the clock source for the on-chip baud rate generator.</p> <p>00: ϕ clock (n = 0)</p> <p>01: $\phi/4$ clock (n = 1)</p> <p>10: $\phi/16$ clock (n = 2)</p> <p>11: $\phi/64$ clock (n = 3)</p> <p>For the relation between the bit rate register setting and the baud rate, see section 14.3.9, Bit Rate Register (BRR). n is the decimal display of the value of n in BRR (see section 14.3.9, Bit Rate Register (BRR)).</p>

14.3.6 Serial Control Register (SCR)

SCR performs enabling or disabling of SCI transfer operations and interrupt requests, and selection of the transfer/receive clock source. For details on interrupt requests, refer to section 14.9, SCI Interrupts. Some bit functions of SCR differ in normal serial communication interface mode and Smart Card interface mode.

Normal Serial Communication Interface Mode (When SMIF in SCMR is 0)

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>When this bit is set to 1, TXI interrupt request is enabled.</p> <p>TXI interrupt request cancellation can be performed by reading 1 from the TDRE flag, then clearing it to 0, or clearing the TIE bit to 0.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>When this bit is set to 1, RXI and ERI interrupt requests are enabled.</p> <p>RXI and ERI interrupt request cancellation can be performed by reading 1 from the RDRF flag, or the FER, PER, or ORER flag, then clearing the flag to 0, or by clearing the RIE bit to 0.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>When this bit is set to 1, transmission is enabled. In this state, serial transmission is started when transmit data is written to TDR and the TDRE flag in SSR is cleared to 0. SMR setting must be performed to decide the transfer format before setting the TE bit to 1.</p> <p>The TDRE flag in SSR is fixed at 1 if transmission is disabled by clearing this bit to 0.</p>
4	RE	0	R/W	<p>Receive Enable</p> <p>When this bit is set to 1, reception is enabled. Serial reception is started in this state when a start bit is detected in asynchronous mode or serial clock input is detected in clocked synchronous mode. SMR setting must be performed to decide the transfer format before setting the RE bit to 1.</p> <p>Clearing the RE bit to 0 does not affect the RDRF, FER, PER, and ORER flags, which retain their states.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	MPIE	0	R/W	<p>Multiprocessor Interrupt Enable (enabled only when the MP bit in SMR is 1 in asynchronous mode)</p> <p>When this bit is set to 1, receive data in which the multiprocessor bit is 0 is skipped, and setting of the RDRF, FER, and ORER status flags in SSR is prohibited. On receiving data in which the multiprocessor bit is 1, this bit is automatically cleared and normal reception is resumed. For details, refer to section 14.5, Multiprocessor Communication Function.</p> <p>When receive data including MPB = 0 in SSR is received, receive data transfer from RSR to RDR, receive error detection, and setting of the RDRF, FER, and ORER flags in SSR, is not performed. When receive data including MPB = 1 is received, the MPB bit in SSR is set to 1, the MPIE bit is cleared to 0 automatically, and generation of RXI and ERI interrupts (when the TIE and RIE bits in SCR are set to 1) and FER and ORER flag setting is enabled.</p>
2	TEIE	0	R/W	<p>Transmit End Interrupt Enable</p> <p>When this bit is set to 1, TEI interrupt request is enabled. TEI cancellation can be performed by reading 1 from the TDRE flag in SSR, then clearing it to 0 and clearing the TEND flag to 0, or by clearing the TEIE bit to 0.</p>
1	CKE1	0	R/W	Clock Enable 1 and 0
0	CKE0	0	R/W	<p>Selects the clock source and SCK pin function.</p> <p>Asynchronous mode</p> <p>00: On-chip baud rate generator SCK pin functions as I/O port</p> <p>01: On-chip baud rate generator (Outputs a clock of the same frequency as the bit rate from the SCK pin.)</p> <p>1X: External clock (Inputs a clock with a frequency 16 times the bit rate from the SCK pin.)</p> <p>Clocked synchronous mode</p> <p>0X: Internal clock (SCK pin functions as clock output)</p> <p>1X: External clock (SCK pin functions as clock input)</p>

Note: X: Don't care

Smart Card Interface Mode (When SMIF in SCMR is 1)

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>When this bit is set to 1, TXI interrupt request is enabled. TXI interrupt request cancellation can be performed by reading 1 from the TDRE flag, then clearing it to 0, or clearing the TIE bit to 0.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>When this bit is set to 1, RXI and ERI interrupt requests are enabled.</p> <p>RXI and ERI interrupt request cancellation can be performed by reading 1 from the RDRF flag, or the FER, PER, or ORER flag, then clearing the flag to 0, or by clearing the RIE bit to 0.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>When this bit is set to 1, transmission is enabled. In this state, serial transmission is started when transmit data is written to TDR and the TDRE flag in SSR is cleared to 0. SMR setting must be performed to decide the transfer format before setting the TE bit to 1.</p> <p>The TDRE flag in SSR is fixed at 1 if transmission is disabled by clearing this bit to 0.</p>
4	RE	0	R/W	<p>Receive Enable</p> <p>When this bit is set to 1, reception is enabled. Serial reception is started in this state when a start bit is detected in asynchronous mode or serial clock input is detected in clocked synchronous mode. SMR setting must be performed to decide the transfer format before setting the RE bit to 1.</p> <p>Clearing the RE bit to 0 does not affect the RDRF, FER, PER, and ORER flags, which retain their states.</p>
3	MPIE	0	R/W	<p>Multiprocessor Interrupt Enable (enabled only when the MP bit in SMR is 1 in asynchronous mode)</p> <p>Write 0 to this bit in Smart Card interface mode.</p>

Bit	Bit Name	Initial Value	R/W	Description
2	TEIE	0	R/W	Transmit End Interrupt Enable Write 0 to this bit in Smart Card interface mode.
1	CKE1	0	R/W	Clock Enable 1 and 0
0	CKE0	0		Enables or disables clock output from the SCK pin. The clock output can be dynamically switched in GSM mode. For details, refer to section 14.7.8, Clock Output Control. When the GM bit in SMR is 0: 00: Output disabled (SCK pin can be used as an I/O port pin) 01: Clock output 1X: Reserved When the GM bit in SMR is 1: 00: Output fixed low 01: Clock output 10: Output fixed high 11: Clock output

Note: X: Don't care

14.3.7 Serial Status Register (SSR)

SSR is a register containing status flags of the SCI and multiprocessor bits for transfer. 1 cannot be written to flags TDRE, RDRF, ORER, PER, and FER; they can only be cleared. Some bit functions of SSR differ in normal serial communication interface mode and Smart Card interface mode.

Normal Serial Communication Interface Mode (When SMIF in SCMR is 0)

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	1	R/(W)* ¹	<p>Transmit Data Register Empty</p> <p>Indicates whether TDR contains transmit data.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none">• When the TE bit in SCR is 0• When data is transferred from TDR to TSR, and data writing to TDR is enabled. <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When 0 is written to TDRE after reading TDRE = 1• When the DMAC*² or DTC is activated by a TXI interrupt request and transfers data to TDR
6	RDRF	0	R/(W) * ¹	<p>Receive Data Register Full</p> <p>Indicates that the received data is stored in RDR.</p> <p>[Setting condition]</p> <p>When serial reception ends normally and receive data is transferred from RSR to RDR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When 0 is written to RDRF after reading RDRF = 1• When the DMAC*² or DTC is activated by an RXI interrupt and transferred data from RDR <p>The RDRF flag is not affected and retains its previous value when the RE bit in SCR is cleared to 0. Exercise care because if reception of the next data is completed while the RDRF flag is set to 1, an overrun error occurs and receive data will be lost.</p>

Bit	Bit Name	Initial Value	R/W	Description
5	ORER	0	R/(W) *1	<p>Overrun Error</p> <p>Indicates that an overrun error occurred while receiving and the reception has ended abnormally.</p> <p>[Setting condition]</p> <p>When the next serial reception is completed while RDRF = 1</p> <p>The receive data prior to the overrun error is retained in RDR, and the data received subsequently is lost. Also, subsequent serial reception cannot be continued while the ORER flag is set to 1. In clocked synchronous mode, serial transmission cannot be continued, either.</p> <p>[Clearing condition]</p> <p>When 0 is written to ORER after reading ORER = 1</p> <p>The ORER flag is not affected and retains its previous state when the RE bit in SCR is cleared to 0.</p>
4	FER	0	R/(W) *1	<p>Framing Error</p> <p>Indicates that a framing error occurred while receiving in asynchronous mode and the reception has ended abnormally.</p> <p>[Setting condition]</p> <p>When the stop bit is 0</p> <p>In 2-stop-bit mode, only the first stop bit is checked for a value of 0; the second stop bit is not checked. If a framing error occurs, the receive data is transferred to RDR but the RDRF flag is not set. Also, subsequent serial reception cannot be continued while the FER flag is set to 1. In clocked synchronous mode, serial transmission cannot be continued, either.</p> <p>[Clearing condition]</p> <p>When 0 is written to FER after reading FER = 1</p> <p>The FER flag is not affected and retains its previous state when the RE bit in SCR is cleared to 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	PER	0	R/(W) *1	<p>Parity Error</p> <p>Indicates that a parity error occurred while receiving in asynchronous mode and the reception has ended abnormally.</p> <p>[Setting condition]</p> <p>When a parity error is detected during reception</p> <p>If a parity error occurs, the receive data is transferred to RDR but the RDRF flag is not set. Also, subsequent serial reception cannot be continued while the PER flag is set to 1. In clocked synchronous mode, serial transmission cannot be continued, either.</p> <p>[Clearing condition]</p> <p>When 0 is written to PER after reading PER = 1</p> <p>The PER flag is not affected and retains its previous state when the RE bit in SCR is cleared to 0.</p>
2	TEND	1	R	<p>Transmit End</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> • When the TE bit in SCR is 0 • When TDRE = 1 at transmission of the last bit of a 1-byte serial transmit character <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • When 0 is written to TDRE after reading TDRE = 1 • When the DMAC or DTC is activated by a TXI interrupt and writes data to TDR
1	MPB	0	R	<p>Multiprocessor Bit</p> <p>MPB stores the multiprocessor bit in the receive data. When the RE bit in SCR is cleared to 0 its previous state is retained.</p>
0	MPBT	0	R/W	<p>Multiprocessor Bit Transfer</p> <p>MPBT sets the multiprocessor bit to be added to the transmit data.</p>

Notes: *1 Only 0 can be written, to clear the flag.

*2 Not supported by the H8S/2366.

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	1	R/(W) * ¹	<p>Transmit Data Register Empty</p> <p>Indicates whether TDR contains transmit data.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When the TE bit in SCR is 0 When data is transferred from TDR to TSR, and data writing to TDR is enabled. <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When 0 is written to TDRE after reading TDRE = 1 When the DMAC*² or DTC is activated by a TXI interrupt request and transfers data to TDR
6	RDRF	0	R/(W) * ¹	<p>Receive Data Register Full</p> <p>Indicates that the received data is stored in RDR.</p> <p>[Setting condition]</p> <p>When serial reception ends normally and receive data is transferred from RSR to RDR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When 0 is written to RDRF after reading RDRF = 1 When the DMAC*² or DTC is activated by an RXI interrupt and transferred data from RDR <p>The RDRF flag is not affected and retains its previous value when the RE bit in SCR is cleared to 0. Exercise care because if reception of the next data is completed while the RDRF flag is set to 1, an overrun error occurs and receive data will be lost.</p>

Bit	Bit Name	Initial Value	R/W	Description
5	ORER	0	R/(W) * ¹	<p>Overrun Error</p> <p>Indicates that an overrun error occurred while receiving and the reception has ended abnormally.</p> <p>[Setting condition]</p> <p>When the next serial reception is completed while RDRF = 1</p> <p>The receive data prior to the overrun error is retained in RDR, and the data received subsequently is lost. Also, subsequent serial reception cannot be continued while the ORER flag is set to 1. In clocked synchronous mode, serial transmission cannot be continued, either.</p> <p>[Clearing condition]</p> <p>When 0 is written to ORER after reading ORER = 1</p> <p>The ORER flag is not affected and retains its previous state when the RE bit in SCR is cleared to 0.</p>
4	ERS	0	R/(W) * ¹	<p>Error Signal Status</p> <p>[Setting condition]</p> <p>When the low level of the error signal is sampled</p> <p>[Clearing condition]</p> <p>When 0 is written to ERS after reading ERS = 1</p>

Bit	Bit Name	Initial Value	R/W	Description
3	PER	0	R/(W) *1	<p>Parity Error</p> <p>Indicates that a parity error occurred while receiving in asynchronous mode and the reception has ended abnormally.</p> <p>[Setting condition]</p> <p>When a parity error is detected during reception</p> <p>If a parity error occurs, the receive data is transferred to RDR but the RDRF flag is not set. Also, subsequent serial reception cannot be continued while the PER flag is set to 1. In clocked synchronous mode, serial transmission cannot be continued, either.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • When 0 is written to PER after reading PER = 1 • The PER flag is not affected and retains its previous state when the RE bit in SCR is cleared to 0.

Bit	Bit Name	Initial Value	R/W	Description
2	TEND	1	R	<p>Transmit End</p> <p>This bit is set to 1 when no error signal has been sent back from the receiving end and the next transmit data is ready to be transferred to TDR.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When the TE bit in SCR is 0 and the ERS bit is also 0 If the ERS bit is 0 and the TDRE bit is 1 after the specified interval after transmission of 1-byte data <p>Timing to set this bit differs according to the register settings.</p> <p>GM = 0, BLK = 0: 2.5 etu after transmission</p> <p>GM = 0, BLK = 1: 1.5 etu after transmission</p> <p>GM = 1, BLK = 0: 1.0 etu after transmission</p> <p>GM = 1, BLK = 1: 1.0 etu after transmission</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> When 0 is written to TEND after reading TEND = 1 When the DMAC or DTC is activated by a TXI interrupt and writes data to TDR
1	MPB	0	R	<p>Multiprocessor Bit</p> <p>This bit is not used in Smart Card interface mode.</p>
0	MPBT	0	R/W	<p>Multiprocessor Bit Transfer</p> <p>Write 0 to this bit in Smart Card interface mode.</p>

Notes: etu: Elementary Time Unit: (time for transfer of 1 bit)

*1 Only 0 can be written, to clear the flag.

*2 Not supported by the H8S/2366.

14.3.8 Smart Card Mode Register (SCMR)

SCMR selects Smart Card interface mode and its format.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	1	—	Reserved These bits are always read as 1.
3	SDIR	0	R/W	Smart Card Data Transfer Direction Selects the serial/parallel conversion format. 0: LSB-first in transfer 1: MSB-first in transfer The bit setting is valid only when the transfer data format is 8 bits. For 7-bit data, LSB-first is fixed.
2	SINV	0	R/W	Smart Card Data Invert Specifies inversion of the data logic level. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the O/E bit in SMR. 0: TDR contents are transmitted as they are. Receive data is stored as it is in RDR. 1: TDR contents are inverted before being transmitted. Receive data is stored in inverted form in RDR.
1	—	1	—	Reserved This bit is always read as 1.
0	SMIF	0	R/W	Smart Card Interface Mode Select This bit is set to 1 to make the SCI operate in Smart Card interface mode. 0: Normal asynchronous mode or clocked synchronous mode 1: Smart card interface mode

14.3.9 Bit Rate Register (BRR)

BRR is an 8-bit register that adjusts the bit rate. As the SCI performs baud rate generator control independently for each channel, different bit rates can be set for each channel. Table 14.2 shows the relationships between the N setting in BRR and bit rate B for normal asynchronous mode, clocked synchronous mode, and Smart Card interface mode. The initial value of BRR is H'FF, and it can be read or written to by the CPU at all times.

Table 14.2 Relationships between N Setting in BRR and Bit Rate B

Mode	Bit Rate	Error
Asynchronous Mode	$B = \frac{\phi \times 10^6}{64 \times 2^{2n-1} \times (N + 1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (N + 1)} - 1 \right\} \times 100$
Clocked Synchronous Mode	$B = \frac{\phi \times 10^6}{8 \times 2^{2n-1} \times (N + 1)}$	
Smart Card Interface Mode	$B = \frac{\phi \times 10^6}{S \times 2^{2n-1} \times (N + 1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times S \times 2^{2n-1} \times (N + 1)} - 1 \right\} \times 100$

Notes: B: Bit rate (bit/s)

N: BRR setting for baud rate generator ($0 \leq N \leq 255$)

ϕ : Operating frequency (MHz)

n and S: Determined by the SMR settings shown in the following tables.

SMR Setting			SMR Setting		
CKS1	CKS0	n	BCP1	BCP0	S
0	0	0	0	0	32
0	1	1	0	1	64
1	0	2	1	0	372
1	1	3	1	1	256

Table 14.3 shows sample N settings in BRR in normal asynchronous mode. Table 14.4 shows the maximum bit rate for each frequency in normal asynchronous mode. Table 14.6 shows sample N settings in BRR in clocked synchronous mode. Table 14.8 shows sample N settings in BRR in Smart Card interface mode. In Smart Card interface mode, S (the number of basic clock periods in a 1-bit transfer interval) can be selected. For details, refer to section 14.7.4, Receive Data Sampling Timing and Reception Margin. Tables 14.5 and 14.7 show the maximum bit rates with external clock input.

14.3.10 IrDA Control Register (IrCR)

IrCR selects the function of SCI_0.

Bit	Bit Name	Initial Value	R/W	Description
7	IrE	0	R/W	IrDA Enable Specifies normal SCI mode or IrDA mode for SCI_0 input/output. 0: Pins TxD0/IrTxD and RxD0/IrRxD function as TxD0 and RxD0 1: Pins TxD0/IrTxD and RxD0/IrRxD function as IrTxD and IrRxD
6	IrCKS2	0	R/W	IrDA Clock Select 2 to 0
5	IrCKS1	0	R/W	Specifies the high pulse width in IrTxD output pulse encoding when the IrDA function is enabled. 000: Pulse width = $B \times 3/16$ (3/16 of bit rate) 001: Pulse width = $\phi/2$ 010: Pulse width = $\phi/4$ 011: Pulse width = $\phi/8$ 100: Pulse width = $\phi/16$ 101: Pulse width = $\phi/32$ 110: Pulse width = $\phi/64$ 111: Pulse width = $\phi/128$
4	IrCKS0	0	R/W	
3	—	0	—	
to				
0				
				Reserved These bits are always read as 0 and cannot be modified.

14.3.11 Serial Extension Mode Register (SEMR)

SEMR selects the clock source in asynchronous mode. The basic clock can be automatically set by selecting the average transfer rate.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	Undefined	—	Reserved If these bits are read, an undefined value will be returned. They cannot be modified.
3	ABCS	0	R/W	Asynchronous basic clock selection (valid only in asynchronous mode) Selects the basic clock for 1-bit period in asynchronous mode. 0: Operates on a basic clock with a frequency of 16 times the transfer rate. 1: Operates on a basic clock with a frequency of 8 times the transfer rate.

Bit	Bit Name	Initial Value	R/W	Description
2	ACS2	0	R/W	Asynchronous clock source selection (valid when CKS1 = 1 in asynchronous mode)
1	ACS1	0	R/W	
0	ACS0	0	R/W	
				Selects the clock source for the average transfer rate.
				The basic clock can be automatically set by selecting the average transfer rate in spite of the value of ABCS.
				000: External clock input
				001: Selects 115.152 kbps which is the average transfer rate dedicated for $\phi = 10.667$ MHz. (Operates on a basic clock with a frequency of 16 times the transfer rate.)
				010: Selects 460.606 kbps which is the average transfer rate dedicated for $\phi = 10.667$ MHz. (Operates on a basic clock with a frequency of 8 times the transfer rate.)
				011: Selects 720 kbps which is the average transfer rate dedicated for $\phi = 32$ MHz. (Operates on a basic clock with a frequency of 16 times the transfer rate.)
				100: Reserved
				101: Selects 115.196 kbps which is the average transfer rate dedicated for $\phi = 16$ MHz (Operates on a basic clock with a frequency of 16 times the transfer rate.)
				110: Selects 460.784 kbps which is the average transfer rate dedicated for $\phi = 16$ MHz (Operates on a basic clock with a frequency of 16 times the transfer rate.)
				111: Selects 720 kbps which is the average transfer rate dedicated for $\phi = 16$ MHz (Operates on a basic clock with a frequency of 8 times the transfer rate.)
				Note that the average transfer rate does not correspond to the frequency other than 10.667, 16, or 32 MHz.

14.4 Operation in Asynchronous Mode

Figure 14.2 shows the general format for asynchronous serial communication. One frame consists of a start bit (low level), followed by transfer data, a parity bit, and finally stop bits (high level). In asynchronous serial communication, the transmission line is usually held in the mark state (high level). The SCI monitors the transmission line, and when it goes to the space state (low level), recognizes a start bit and starts serial communication. In asynchronous serial communication, the communication line is usually held in the mark state (high level). The SCI monitors the communication line, and when it goes to the space state (low level), recognizes a start bit and starts serial communication. Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communication. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transfer.

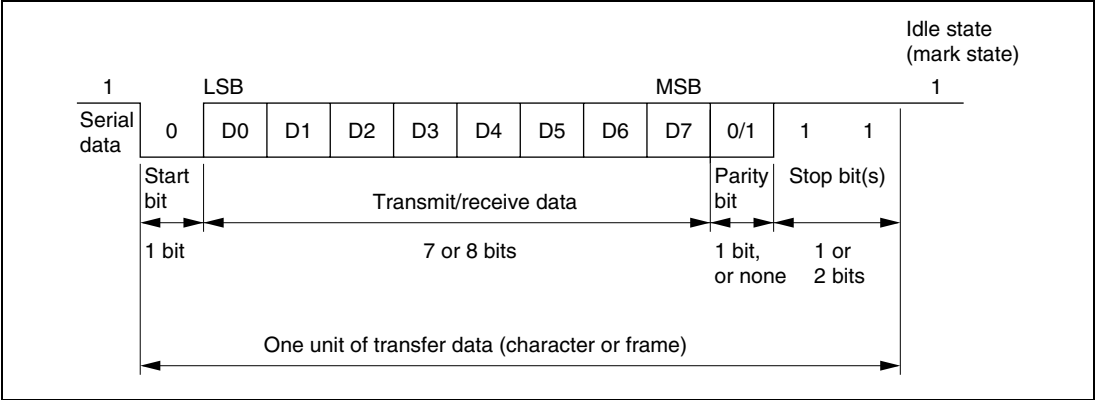

Figure 14.2 Data Format in Asynchronous Communication
(Example with 8-Bit Data, Parity, Two Stop Bits)

14.4.1 Data Transfer Format

Table 14.10 shows the data transfer formats that can be used in asynchronous mode. Any of 12 transfer formats can be selected according to the SMR setting. For details on the multiprocessor bit, refer to section 14.5, Multiprocessor Communication Function.

Table 14.10 Serial Transfer Formats (Asynchronous Mode)

SMR Settings				Serial Transfer Format and Frame Length											
CHR	PE	MP	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	0	S	8-bit data								STOP		
0	0	0	1	S	8-bit data								STOP	STOP	
0	1	0	0	S	8-bit data								P	STOP	
0	1	0	1	S	8-bit data								P	STOP	STOP

S : Start bit

STOP : Stop bit

P : Parity bit

MPB : Multiprocessor bit

14.4.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a basic clock with a frequency of 16 times the bit rate. In reception, the SCI samples the falling edge of the start bit using the basic clock, and performs internal synchronization. Receive data is latched at the middle of each bit by sampling the data at the rising edge of the 8th pulse of the basic clock as shown in figure 14.3. Thus the reception margin in asynchronous mode is given by formula (1) below.

$$M = \left\{ \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right\} \times 100 [\%]$$

... Formula (1)

Where M: Reception Margin

N: Ratio of bit rate to clock (N = 16)

D: Clock duty (D = 0.5 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock rate deviation

Assuming values of F = 0 and D = 0.5 in formula (1), a reception margin is given by formula below.

$$M = \{ 0.5 - 1/(2 \times 16) \} \times 100 [\%] = 46.875\%$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

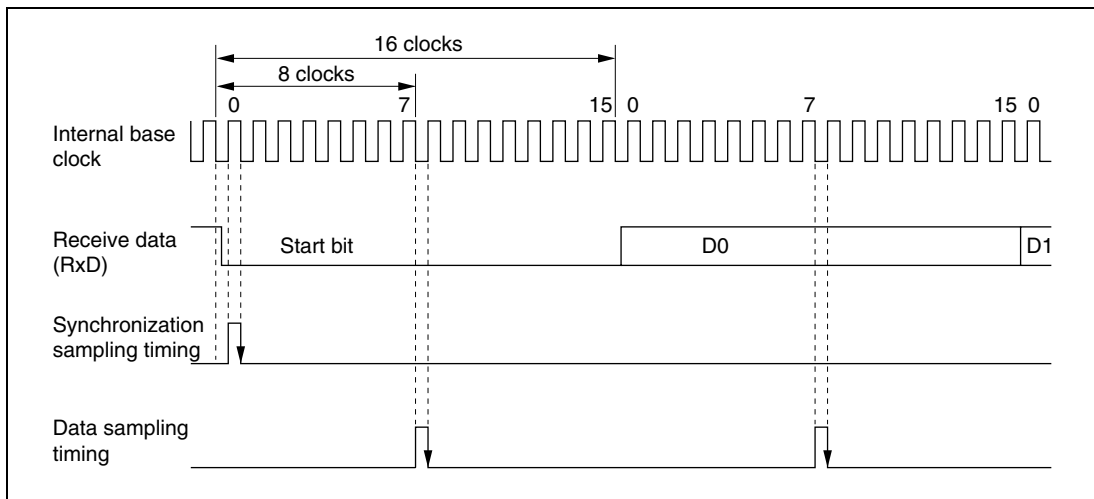

Figure 14.3 Receive Data Sampling Timing in Asynchronous Mode

14.4.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input at the SCK pin can be selected as the SCI's serial clock, according to the setting of the C/\overline{A} bit in SMR and the CKE1 and CKE0 bits in SCR. When an external clock is input at the SCK pin, the clock frequency should be 16 times the bit rate used.

When the SCI is operated on an internal clock, the clock can be output from the SCK pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in figure 14.4.

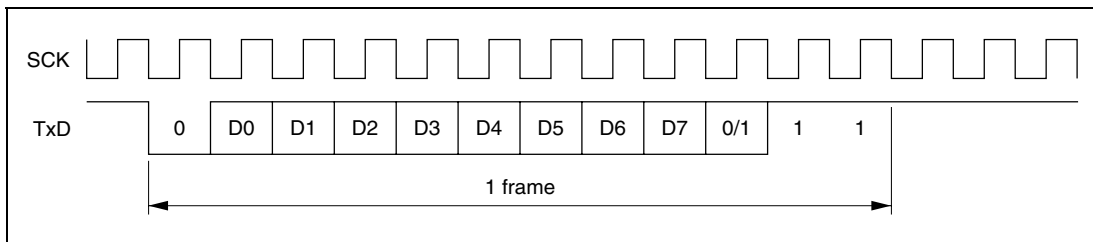

Figure 14.4 Relation between Output Clock and Transfer Data Phase (Asynchronous Mode)

14.4.4 SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, you should first clear the TE and RE bits in SCR to 0, then initialize the SCI as shown in figure 14.5. When the operating mode, transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change. When the TE bit is cleared to 0, the TDRE flag is set to 1. Note that clearing the RE bit to 0 does not initialize the contents of the RDRF, PER, FER, and ORER flags, or the contents of RDR. When the external clock is used in asynchronous mode, the clock must be supplied even during initialization.

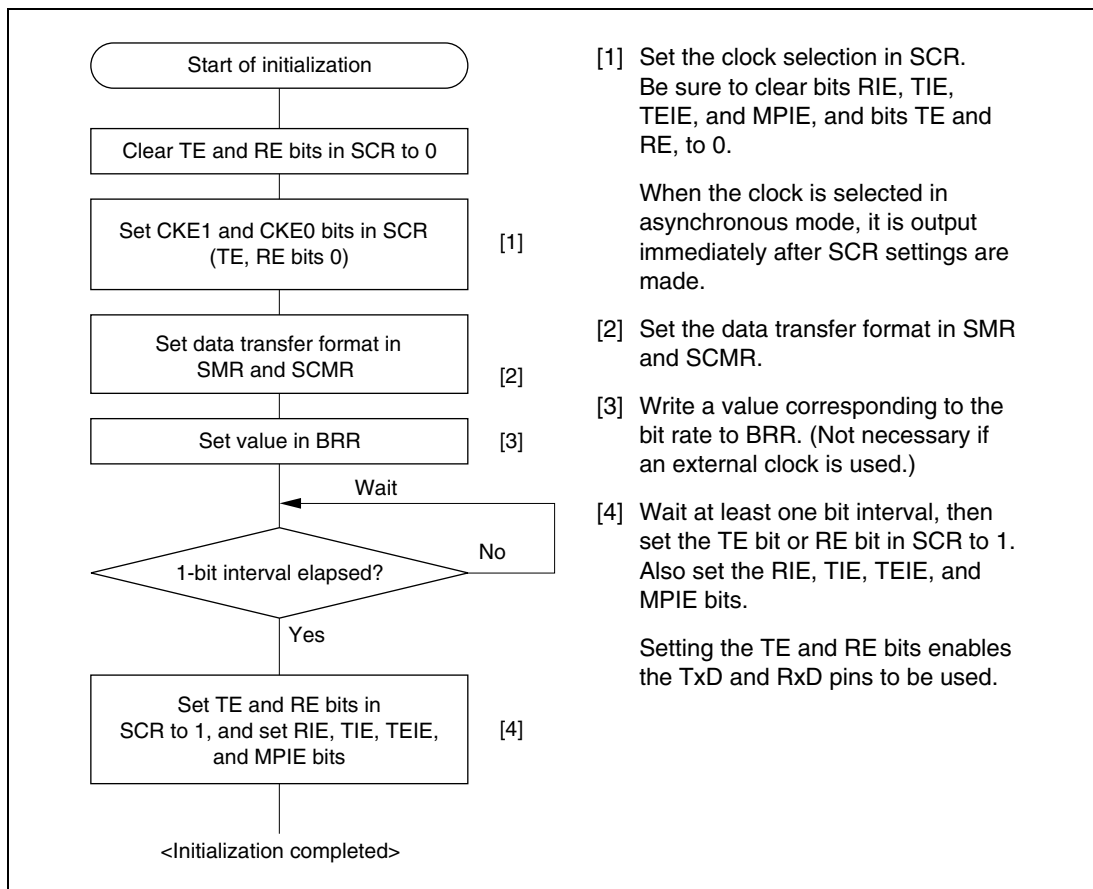

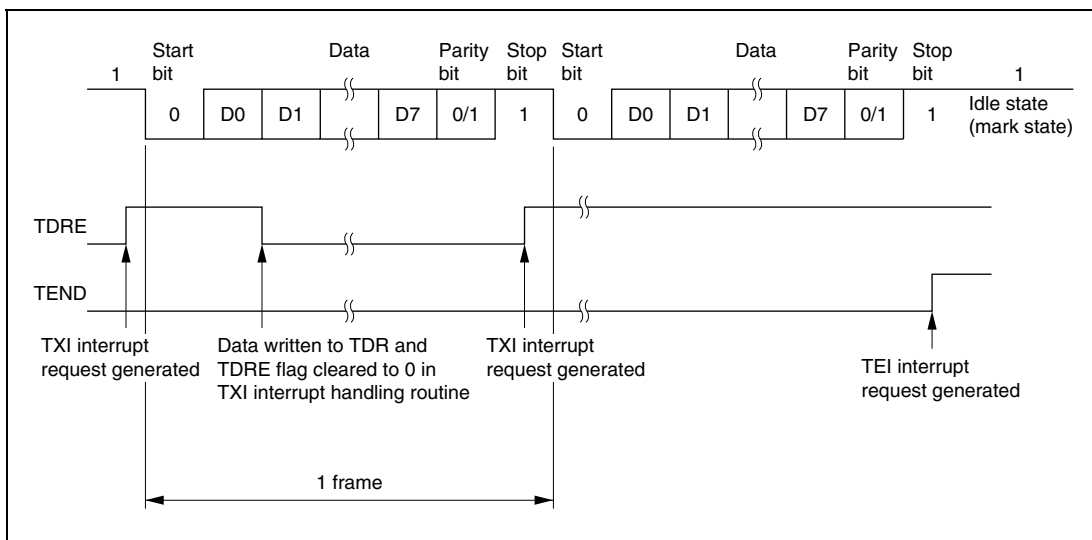

Figure 14.5 Sample SCI Initialization Flowchart

14.4.5 Data Transmission (Asynchronous Mode)

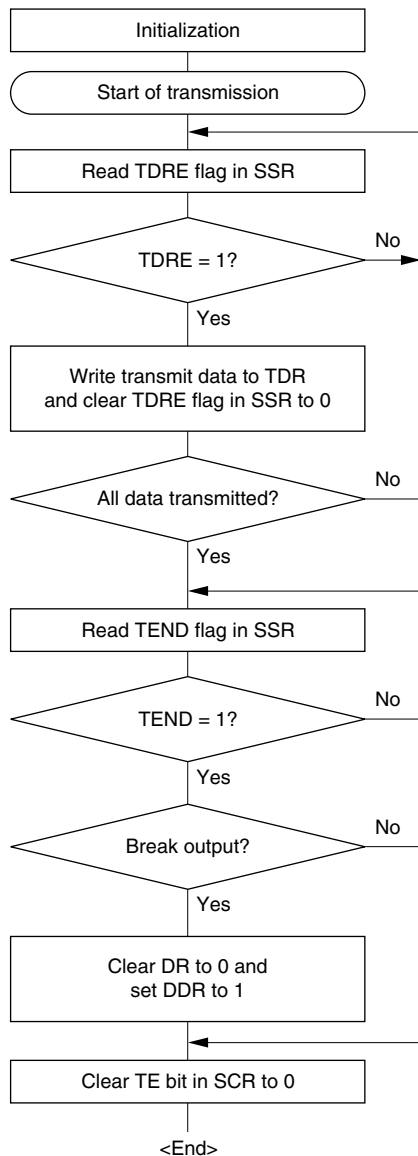

Figure 14.6 shows an example of the operation for transmission in asynchronous mode. In transmission, the SCI operates as described below.

1. The SCI monitors the TDRE flag in SSR, and if it is cleared to 0, recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
2. After transferring data from TDR to TSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit is set to 1 at this time, a transmit data empty interrupt request (TXI) is generated. Because the TXI interrupt routine writes the next transmit data to TDR before transmission of the current transmit data has finished, continuous transmission can be enabled.
3. Data is sent from the TxD pin in the following order: start bit, transmit data, parity bit or multiprocessor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks the TDRE flag at the timing for sending the stop bit.
5. If the TDRE flag is 0, the data is transferred from TDR to TSR, the stop bit is sent, and then serial transmission of the next frame is started.
6. If the TDRE flag is 1, the TEND flag in SSR is set to 1, the stop bit is sent, and then the “mark state” is entered in which 1 is output. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 14.7 shows a sample flowchart for transmission in asynchronous mode.

**Figure 14.6 Example of Operation in Transmission in Asynchronous Mode
(Example with 8-Bit Data, Parity, One Stop Bit)**

- [1] [1] SCI initialization:
The TxD pin is automatically designated as the transmit data output pin.
After the TE bit is set to 1, a frame of 1s is output, and transmission is enabled.
- [2] [2] SCI status check and transmit data write:
Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR and clear the TDRE flag to 0.
- [3] [3] Serial transmission continuation procedure:
To continue serial transmission, read 1 from the TDRE flag to confirm that writing is possible, then write data to TDR, and then clear the TDRE flag to 0. Checking and clearing of the TDRE flag is automatic when the DMAC* or DTC is activated by a transmit-data-empty interrupt (TXI) request, and data is written to TDR.
- [4] [4] Break output at the end of serial transmission:
To output a break in serial transmission, set DDR for the port corresponding to the TxD pin to 1, clear DR to 0, then clear the TE bit in SCR to 0.

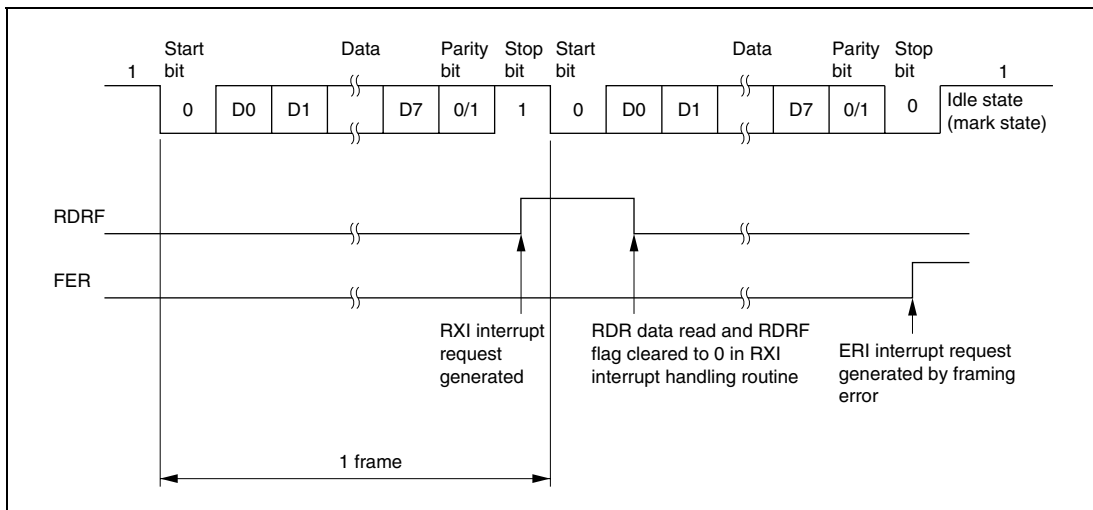

Note: * Not supported by the H8S/2366.

Figure 14.7 Sample Serial Transmission Flowchart

14.4.6 Serial Data Reception (Asynchronous Mode)

Figure 14.8 shows an example of the operation for reception in asynchronous mode. In serial reception, the SCI operates as described below.

1. The SCI monitors the communication line, and if a start bit is detected, performs internal synchronization, receives receive data in RSR, and checks the parity bit and stop bit.
2. If an overrun error (when reception of the next data is completed while the RDRF flag is still set to 1) occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR. The RDRF flag remains to be set to 1.
3. If a parity error is detected, the PER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
4. If a framing error (when the stop bit is 0) is detected, the FER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
5. If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt routine reads the receive data transferred to RDR before reception of the next receive data has finished, continuous reception can be enabled.

**Figure 14.8 Example of SCI Operation in Reception
(Example with 8-Bit Data, Parity, One Stop Bit)**

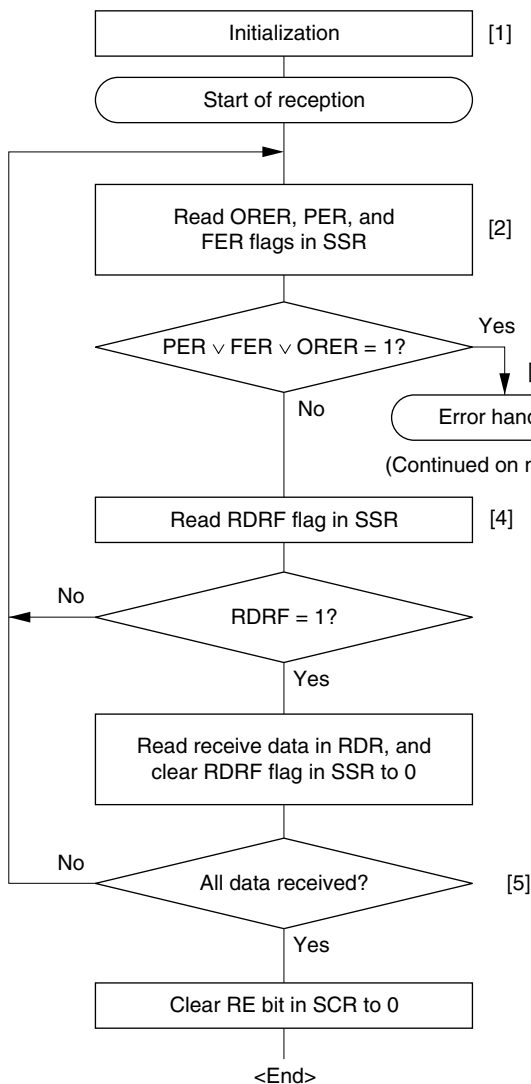

Table 14.11 shows the states of the SSR status flags and receive data handling when a receive error is detected. If a receive error is detected, the RDRF flag retains its state before receiving data. Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the

ORER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 14.9 shows a sample flowchart for serial data reception.

Table 14.11 SSR Status Flags and Receive Data Handling

SSR Status Flag				Receive Data	Receive Error Type
RDRF*	ORER	FER	PER		
1	1	0	0	Lost	Overrun error
0	0	1	0	Transferred to RDR	Framing error
0	0	0	1	Transferred to RDR	Parity error
1	1	1	0	Lost	Overrun error + framing error
1	1	0	1	Lost	Overrun error + parity error
0	0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	1	Lost	Overrun error + framing error + parity error

Note: *The RDRF flag retains its state before data reception.

- [1] SCI initialization:
The RxD pin is automatically designated as the receive data input pin.
- [2] [3] Receive error handling and break detection:
If a receive error occurs, read the ORER, PER, and FER flags in SSR to identify the error. After performing the appropriate error processing, ensure that the ORER, PER, and FER flags are all cleared to 0. Reception cannot be resumed if any of these flags are set to 1. In the case of a framing error, a break can be detected by reading the value of the input port corresponding to the RxD pin.
- [4] SCI status check and receive data read :
Read SSR and check that RDRF = 1, then read the receive data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [5] Serial reception continuation procedure:
To continue serial reception, before the stop bit for the current frame is received, read the RDRF flag, read RDR, and clear the RDRF flag to 0. The RDRF flag is cleared automatically when the DMAC* or DTC is activated by an RXI interrupt and the RDR value is read.

Note: * Not supported by the H8S/2366.

Figure 14.9 Sample Serial Reception Data Flowchart (1)

[3]

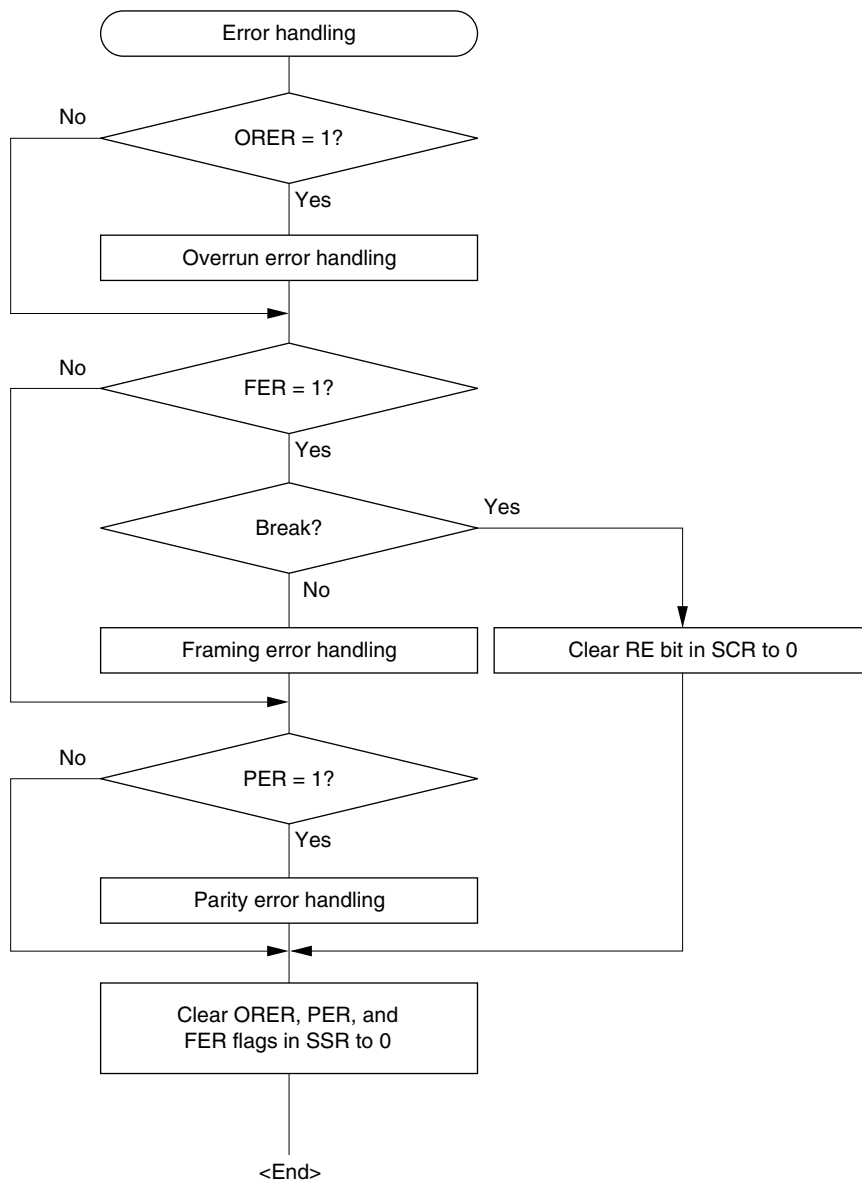

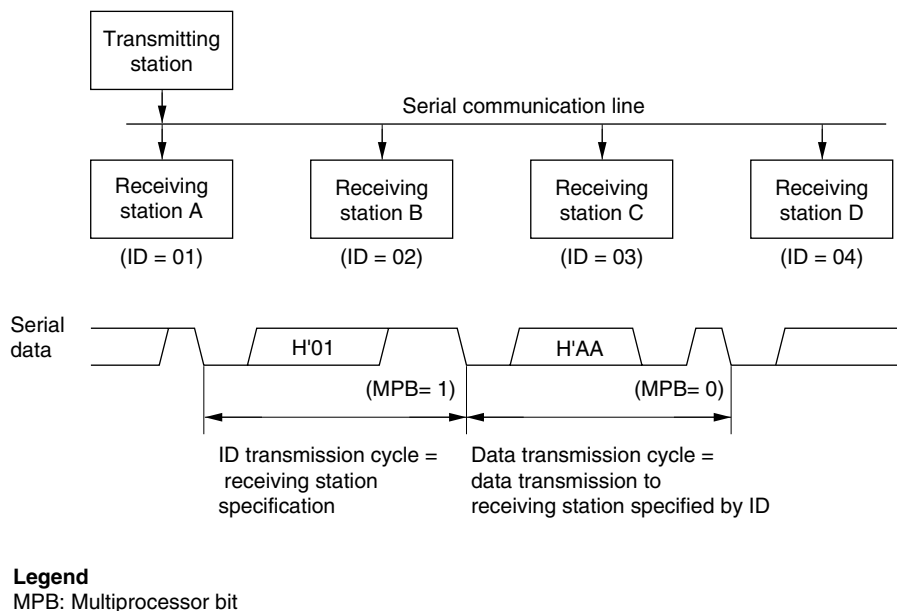

Figure 14.9 Sample Serial Reception Data Flowchart (2)

14.5 Multiprocessor Communication Function

Use of the multiprocessor communication function enables data transfer to be performed among a number of processors sharing communication lines by means of asynchronous serial communication using the multiprocessor format, in which a multiprocessor bit is added to the transfer data. When multiprocessor communication is carried out, each receiving station is addressed by a unique ID code. The serial communication cycle consists of two component cycles: an ID transmission cycle which specifies the receiving station, and a data transmission cycle to the specified receiving station. The multiprocessor bit is used to differentiate between the ID transmission cycle and the data transmission cycle. If the multiprocessor bit is 1, the cycle is an ID transmission cycle, and if the multiprocessor bit is 0, the cycle is a data transmission cycle. Figure 14.10 shows an example of inter-processor communication using the multiprocessor format. The transmitting station first sends communication data with a 1 multiprocessor bit added to the ID code of the receiving station. It then sends transmit data as data with a 0 multiprocessor bit added. When data with a 1 multiprocessor bit is received, the receiving station compares that data with its own ID. The station whose ID matches then receives the data sent next. Stations whose ID does not match continue to skip data until data with a 1 multiprocessor bit is again received.

The SCI uses the MPIE bit in SCR to implement this function. When the MPIE bit is set to 1, transfer of receive data from RSR to RDR, error flag detection, and setting the SSR status flags, RDRF, FER, and ORER to 1 are inhibited until data with a 1 multiprocessor bit is received. On reception of receive character with a 1 multiprocessor bit, the MPBR bit in SSR is set to 1 and the MPIE bit is automatically cleared, thus normal reception is resumed. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt is generated.

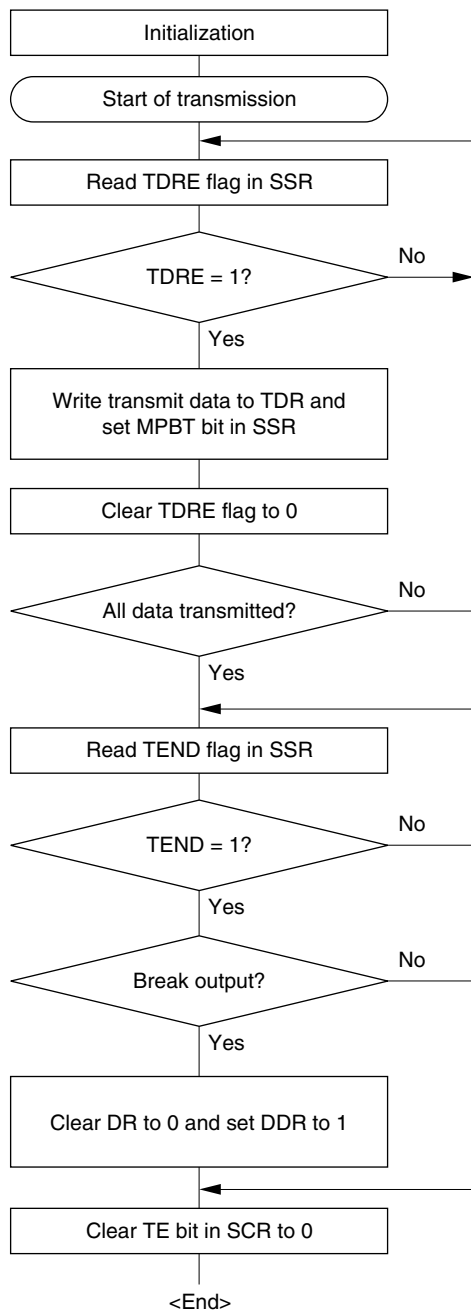

When the multiprocessor format is selected, the parity bit setting is invalid. All other bit settings are the same as those in normal asynchronous mode. The clock used for multiprocessor communication is the same as that in normal asynchronous mode.

**Figure 14.10 Example of Communication Using Multiprocessor Format
(Transmission of Data H'AA to Receiving Station A)**

14.5.1 Multiprocessor Serial Data Transmission

Figure 14.11 shows a sample flowchart for multiprocessor serial data transmission. For an ID transmission cycle, set the MPBT bit in SSR to 1 before transmission. For a data transmission cycle, clear the MPBT bit in SSR to 0 before transmission. All other SCI operations are the same as those in asynchronous mode.

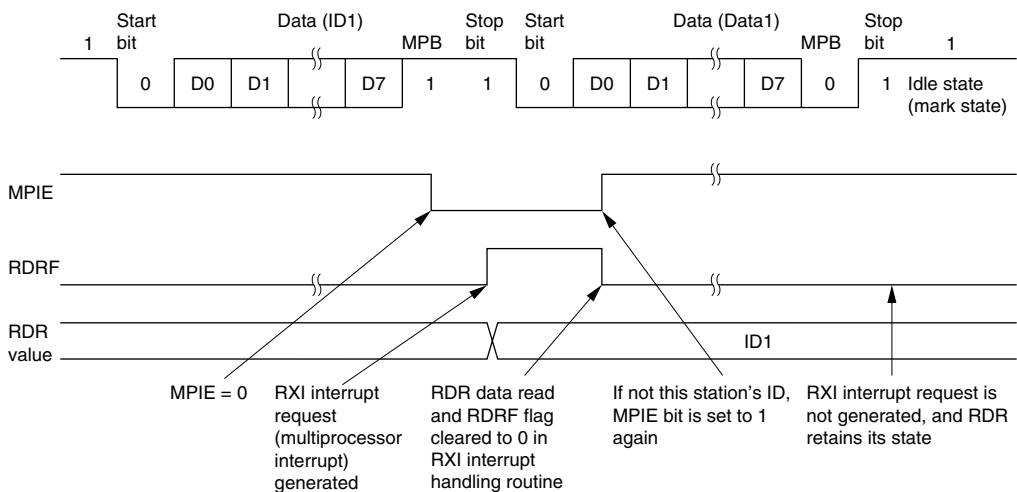

- [1] [1] SCI initialization:
The TxD pin is automatically designated as the transmit data output pin.
After the TE bit is set to 1, a frame of 1s is output, and transmission is enabled.
- [2] [2] SCI status check and transmit data write:
Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR. Set the MPBT bit in SSR to 0 or 1.
Finally, clear the TDRE flag to 0.
- [3] [3] Serial transmission continuation procedure:
To continue serial transmission, be sure to read 1 from the TDRE flag to confirm that writing is possible, then write data to TDR, and then clear the TDRE flag to 0. Checking and clearing of the TDRE flag is automatic when the DMAC* or DTC is activated by a transmit-data-empty interrupt (TXI) request, and data is written to TDR.
- [4] [4] Break output at the end of serial transmission:
To output a break in serial transmission, set the port DDR to 1, clear DR to 0, then clear the TE bit in SCR to 0.

Note: * Not supported by the H8S/2366.

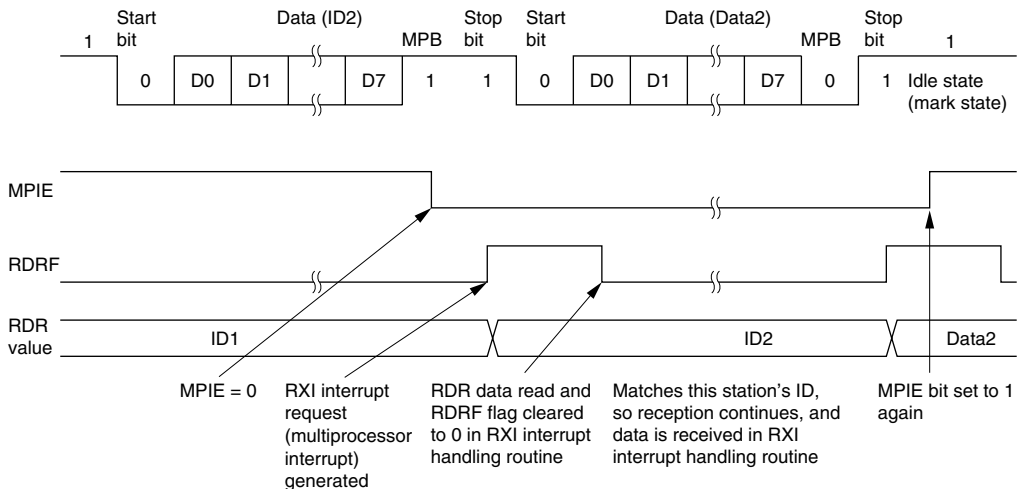

Figure 14.11 Sample Multiprocessor Serial Transmission Flowchart

14.5.2 Multiprocessor Serial Data Reception

Figure 14.13 shows a sample flowchart for multiprocessor serial data reception. If the MPIE bit in SCR is set to 1, data is skipped until data with a 1 multiprocessor bit is received. On receiving data with a 1 multiprocessor bit, the receive data is transferred to RDR. An RXI interrupt request is generated at this time. All other SCI operations are the same as in asynchronous mode. Figure 14.12 shows an example of SCI operation for multiprocessor format reception.

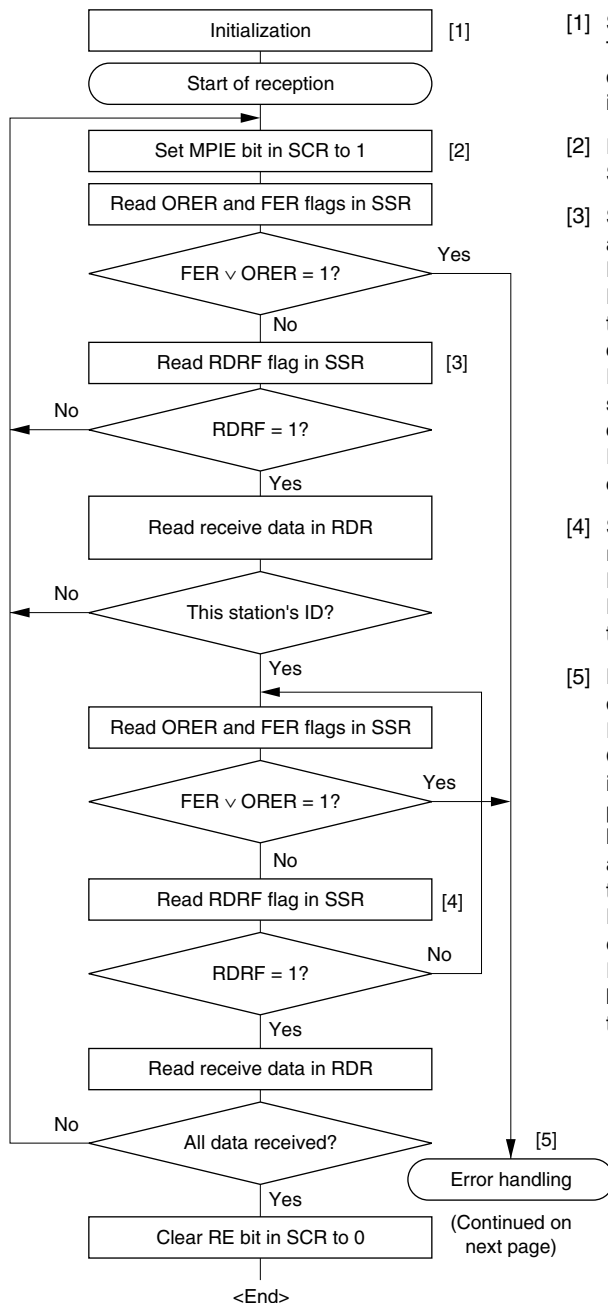

(a) Data does not match station's ID

(b) Data matches station's ID

**Figure 14.12 Example of SCI Operation in Reception
(Example with 8-Bit Data, Multiprocessor Bit, One Stop Bit)**

- [1] SCI initialization:
The Rx/D pin is automatically designated as the receive data input pin.
- [2] ID reception cycle:
Set the MPIE bit in SCR to 1.
- [3] SCI status check, ID reception and comparison:
Read SSR and check that the RDRF flag is set to 1, then read the receive data in RDR and compare it with this station's ID. If the data is not this station's ID, set the MPIE bit to 1 again, and clear the RDRF flag to 0. If the data is this station's ID, clear the RDRF flag to 0.
- [4] SCI status check and data reception:
Read SSR and check that the RDRF flag is set to 1, then read the data in RDR.
- [5] Receive error handling and break detection:
If a receive error occurs, read the ORER and FER flags in SSR to identify the error. After performing the appropriate error handling, ensure that the ORER and FER flags are both cleared to 0. Reception cannot be resumed if either of these flags is set to 1. In the case of a framing error, a break can be detected by reading the Rx/D pin value.

Figure 14.13 Sample Multiprocessor Serial Reception Flowchart (1)

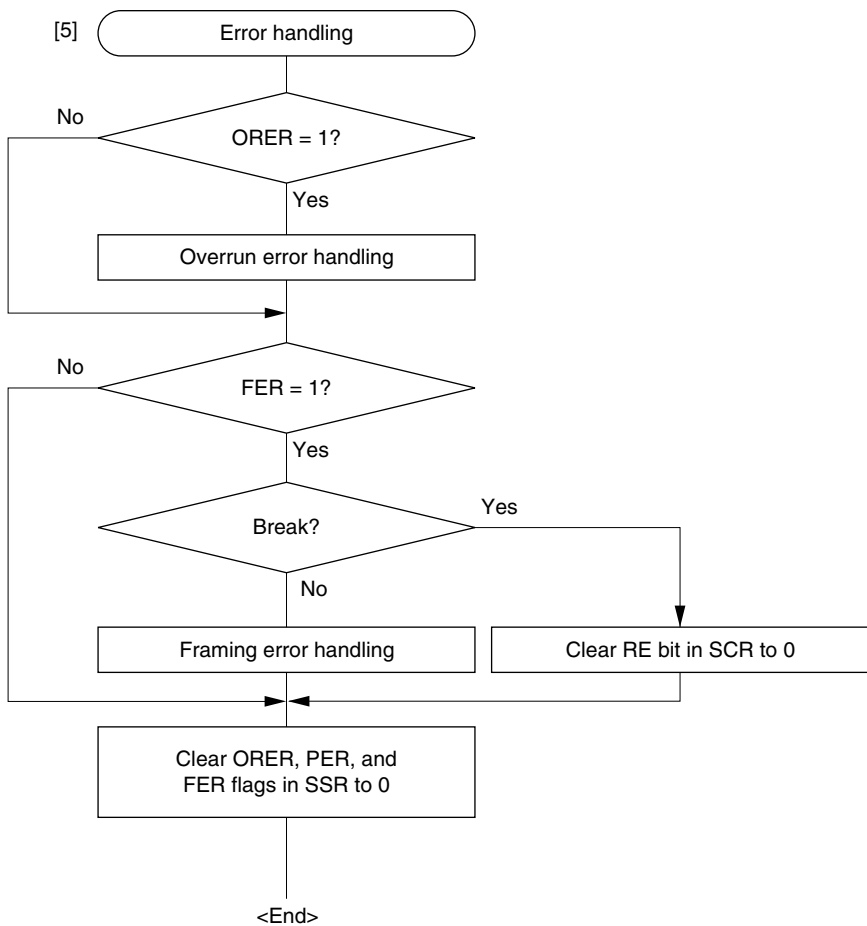

Figure 14.13 Sample Multiprocessor Serial Reception Flowchart (2)

14.6 Operation in Clocked Synchronous Mode

Figure 14.14 shows the general format for clocked synchronous communication. In clocked synchronous mode, data is transmitted or received in synchronization with clock pulses. One character of communication data consists of 8-bit data. In clocked synchronous serial communication, data on the transmission line is output from one falling edge of the serial clock to the next. In clocked synchronous mode, the SCI receives data in synchronization with the rising edge of the serial clock. After 8-bit data is output, the transmission line holds the MSB state. In clocked synchronous mode, no parity or multiprocessor bit is added. Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communication by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transfer.

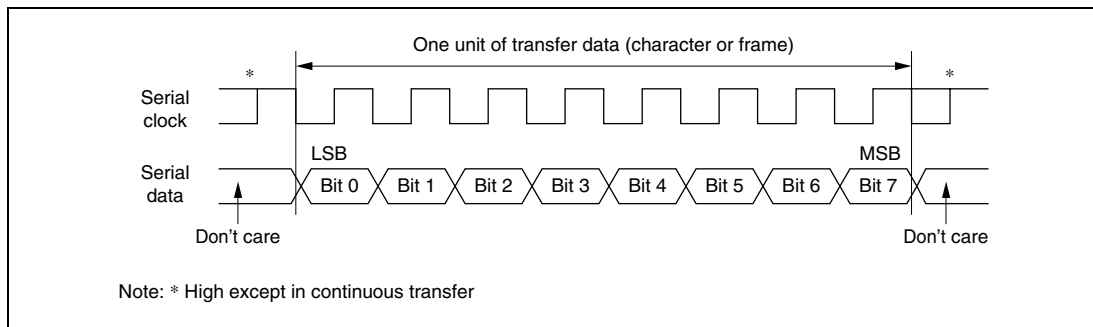

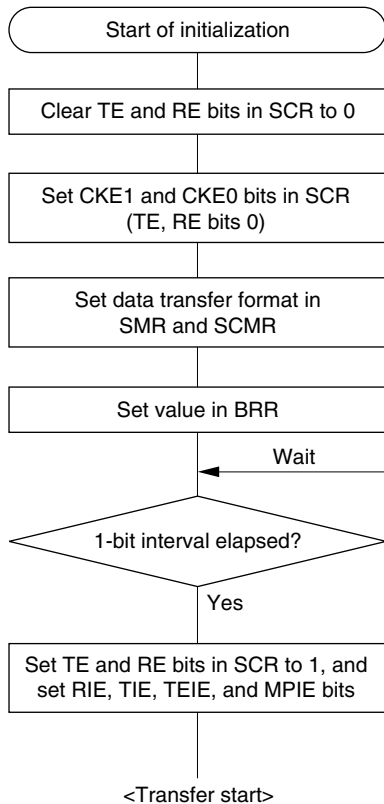

Figure 14.14 Data Format in Clocked Synchronous Communication (For LSB-First)

14.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCK pin can be selected, according to the setting of CKE1 and CKE0 bits in SCR. When the SCI is operated on an internal clock, the serial clock is output from the SCK pin. Eight serial clock pulses are output in the transfer of one character, and when no transfer is performed the clock is fixed high.

14.6.2 SCI Initialization (Clocked Synchronous Mode)

Before transmitting and receiving data, you should first clear the TE and RE bits in SCR to 0, then initialize the SCI as described in a sample flowchart in figure 14.15. When the operating mode, transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change. When the TE bit is cleared to 0, the TDRE flag is set to 1. Note that clearing the RE bit to 0 does not change the contents of the RDRF, PER, FER, and ORER flags, or the contents of RDR.

[1] Set the clock selection in SCR. Be sure to clear bits RIE, TIE, TEIE, and MPIE, TE and RE, to 0.

[2] Set the data transfer format in SMR and SCMR.

[3] Write a value corresponding to the bit rate to BRR. (Not necessary if an external clock is used.)

[4] Wait at least one bit interval, then set the TE and RE bits in SCR to 1. Also set the RIE, TIE, TEIE, and MPIE bits. Setting the TE and RE bits enable the TxD and RxD pins to be used.

Note: In simultaneous transmit and receive operations, the TE and RE bits should both be cleared to 0 or set to 1 simultaneously.

Figure 14.15 Sample SCI Initialization Flowchart

14.6.3 Serial Data Transmission (Clocked Synchronous Mode)

Figure 14.16 shows an example of SCI operation for transmission in clocked synchronous mode. In serial transmission, the SCI operates as described below.

1. The SCI monitors the TDRE flag in SSR, and if it is 0, recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
2. After transferring data from TDR to TSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit in SCR is set to 1 at this time, a TXI interrupt request is generated. Because the TXI interrupt routine writes the next transmit data to TDR before transmission of the current transmit data has finished, continuous transmission can be enabled.
3. 8-bit data is sent from the TxD pin synchronized with the output clock when output clock mode has been specified and synchronized with the input clock when use of an external clock has been specified.
4. The SCI checks the TDRE flag at the timing for sending the MSB.
5. If the TDRE flag is cleared to 0, data is transferred from TDR to TSR, and serial transmission of the next frame is started.
6. If the TDRE flag is set to 1, the TEND flag in SSR is set to 1, and the TxD pin maintains the output state of the last bit. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt request is generated. The SCK pin is fixed high.

Figure 14.17 shows a sample flowchart for serial data transmission. Even if the TDRE flag is cleared to 0, transmission will not start while a receive error flag (ORER, FER, or PER) is set to 1. Make sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

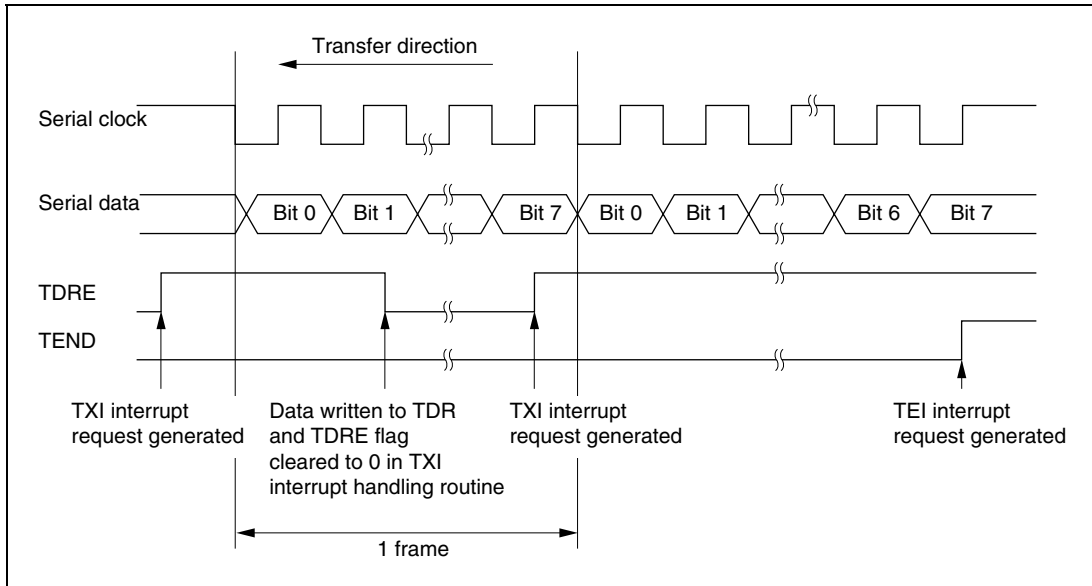

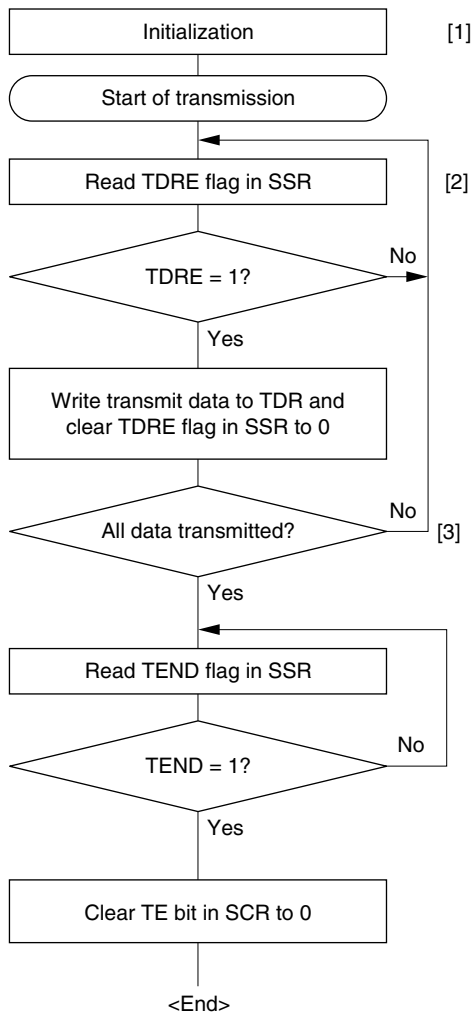

Figure 14.16 Sample SCI Transmission Operation in Clocked Synchronous Mode

[1] SCI initialization:
The TxD pin is automatically designated as the transmit data output pin.

[2] SCI status check and transmit data write:
Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR and clear the TDRE flag to 0.

[3] Serial transmission continuation procedure:
To continue serial transmission, be sure to read 1 from the TDRE flag to confirm that writing is possible, then write data to TDR, and then clear the TDRE flag to 0.
Checking and clearing of the TDRE flag is automatic when the DMAC* or DTC is activated by a transmit-data-empty interrupt (TXI) request and data is written to TDR.

Note: * Not supported by the H8S/2366.

Figure 14.17 Sample Serial Transmission Flowchart

14.6.4 Serial Data Reception (Clocked Synchronous Mode)

Figure 14.18 shows an example of SCI operation for reception in clocked synchronous mode. In serial reception, the SCI operates as described below.

1. The SCI performs internal initialization in synchronization with a synchronization clock input or output, starts receiving data, and stores the received data in RSR.
2. If an overrun error (when reception of the next data is completed while the RDRF flag is still set to 1) occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR. The RDRF flag remains to be set to 1.
3. If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt routine reads the receive data transferred to RDR before reception of the next receive data has finished, continuous reception can be enabled.

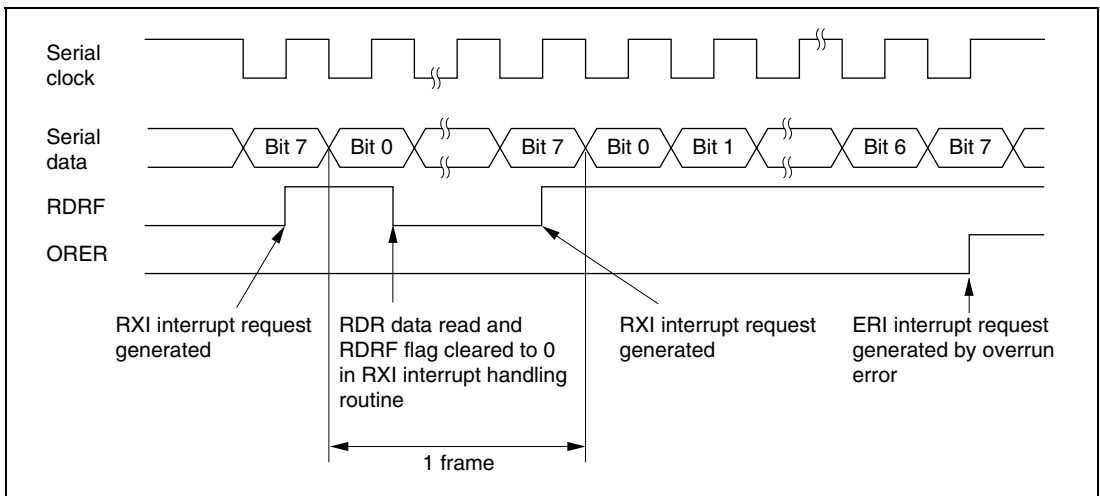

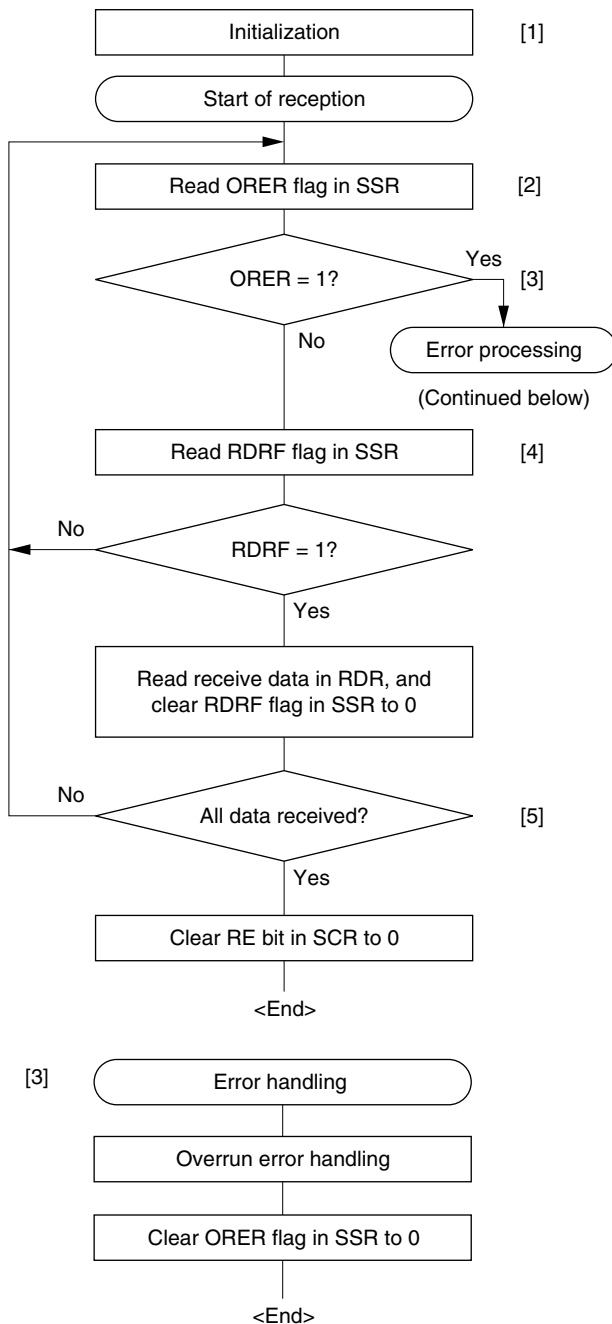

Figure 14.18 Example of SCI Operation in Reception

Transfer cannot be resumed while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 14.19 shows a sample flowchart for serial data reception.

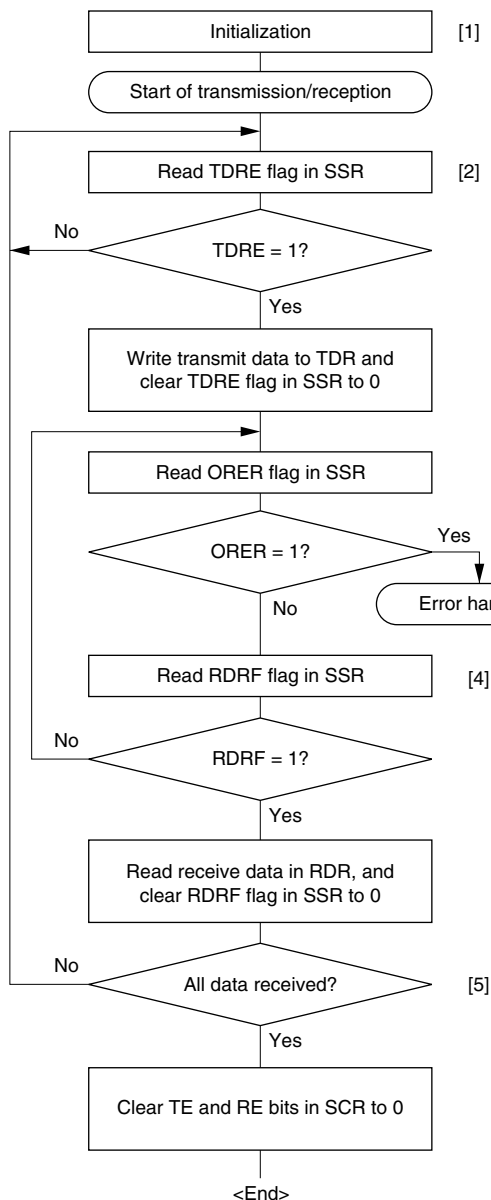

- [1] SCI initialization:
The Rx/D pin is automatically designated as the receive data input pin.
- [2] [3] Receive error handling:
If a receive error occurs, read the ORER flag in SSR, and after performing the appropriate error handling, clear the ORER flag to 0. Transfer cannot be resumed if the ORER flag is set to 1.
- [4] SCI status check and receive data read:
Read SSR and check that the RDRF flag is set to 1, then read the receive data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [5] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, finish reading the RDRF flag, reading RDR, and clearing the RDRF flag to 0. The RDRF flag is cleared automatically when the DMAC* or DTC is activated by a receive-data-full interrupt (RXI) request and the RDR value is read.

Note: * Not supported by the H8S/2366.

Figure 14.19 Sample Serial Reception Flowchart

14.6.5 Simultaneous Serial Data Transmission and Reception (Clocked Synchronous Mode)

Figure 14.20 shows a sample flowchart for simultaneous serial transmit and receive operations. The following procedure should be used for simultaneous serial data transmit and receive operations after the SCI is initialized. To switch from transmit mode to simultaneous transmit and receive mode, after checking that the SCI has finished transmission and the TDRE and TEND flags are set to 1, clear TE to 0. Then simultaneously set TE and RE to 1 with a single instruction. To switch from receive mode to simultaneous transmit and receive mode, after checking that the SCI has finished reception, clear RE to 0. Then after checking that the RDRF and receive error flags (ORER, FER, and PER) are cleared to 0, simultaneously set TE and RE to 1 with a single instruction.

- [1] **SCI initialization:**
The TxD pin is designated as the transmit data output pin, and the RxD pin is designated as the receive data input pin, enabling simultaneous transmit and receive operations.
- [2] **SCI status check and transmit data write:**
Read SSR and check that the TDRE flag is set to 1, then write transmit data to TDR and clear the TDRE flag to 0. Transition of the TDRE flag from 0 to 1 can also be identified by a TXI interrupt.
- [3] **Receive error handling:**
If a receive error occurs, read the ORER flag in SSR, and after performing the appropriate error handling, clear the ORER flag to 0. Transmission/reception cannot be resumed if the ORER flag is set to 1.
- [4] **SCI status check and receive data read:**
Read SSR and check that the RDRF flag is set to 1, then read the receive data in RDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [5] **Serial transmission/reception continuation procedure:**
To continue serial transmission/reception, before the MSB (bit 7) of the current frame is received, finish reading the RDRF flag, reading RDR, and clearing the RDRF flag to 0. Also, before the MSB (bit 7) of the current frame is transmitted, read 1 from the TDRE flag to confirm that writing is possible. Then write data to TDR and clear the TDRE flag to 0. Checking and clearing of the TDRE flag is automatic when the DMAC* or DTC is activated by a transmit-data-empty interrupt (TXI) request and data is written to TDR. Also, the RDRF flag is cleared automatically when the DMAC or DTC is activated by a receive-data-full interrupt (RXI) request and the RDR value is read.

Notes: When switching from transmit or receive operation to simultaneous transmit and receive operations, first clear the TE and RE bits to 0, then set both these bits to 1 simultaneously.
* Not supported by the H8S/2366.

Figure 14.20 Sample Flowchart of Simultaneous Serial Transmit and Receive Operations

14.7 Operation in Smart Card Interface Mode

The SCI supports an IC card (Smart Card) interface conforming to ISO/IEC 7816-3 (Identification Card) as a serial communication interface extension function. Switching between the normal serial communication interface and the Smart Card interface is carried out by means of a register setting.

14.7.1 Pin Connection Example

Figure 14.21 shows an example of connection with the Smart Card. In communication with an IC card, since both transmission and reception are carried out on a single data transmission line, the Tx/D pin and Rx/D pin should be connected with the LSI pin. The data transmission line should be pulled up to the V_{CC} power supply with a resistor. If an IC card is not connected, and the TE and RE bits are both set to 1, closed transmission/reception is possible, enabling self-diagnosis to be carried out. When the clock generated on the SCI is used by an IC card, the SCK pin output is input to the CLK pin of the IC card. This LSI port output is used as the reset signal.

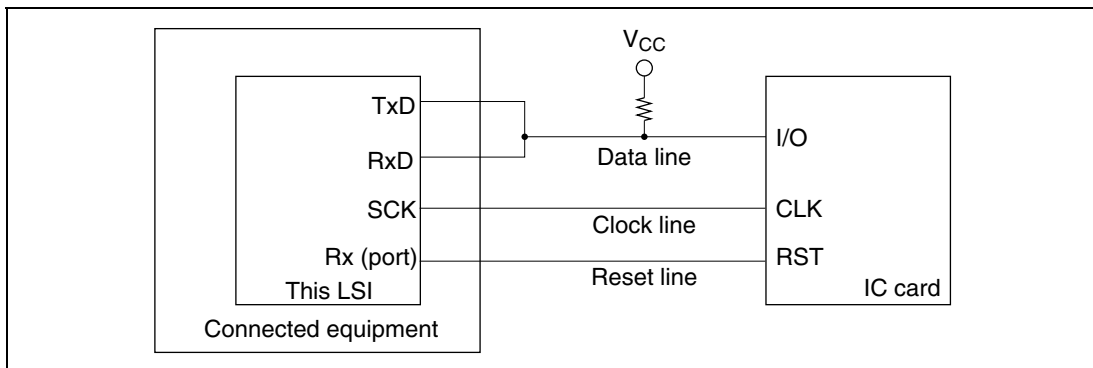

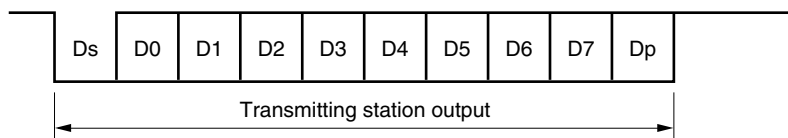

Figure 14.21 Schematic Diagram of Smart Card Interface Pin Connections

14.7.2 Data Format (Except for Block Transfer Mode)

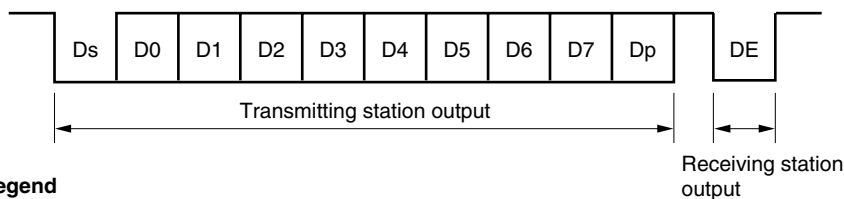

Figure 14.22 shows the transfer data format in Smart Card interface mode.

- One frame consists of 8-bit data plus a parity bit in asynchronous mode.
- In transmission, a guard time of at least 2 etu (Elementary Time Unit: time for transfer of 1 bit) is left between the end of the parity bit and the start of the next frame.
- If a parity error is detected during reception, a low error signal level is output for one etu period, 10.5 etu after the start bit.
- If an error signal is sampled during transmission, the same data is retransmitted automatically after the elapse of 2 etu or longer.

When there is no parity error

When a parity error occurs

Legend

Ds : Start bit
D0 to D7 : Data bits
Dp : Parity bit
DE : Error signal

Figure 14.22 Normal Smart Card Interface Data Format

Data transfer with the types of IC cards (direct convention and inverse convention) are performed as described in the following.

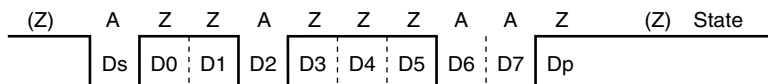

Figure 14.23 Direct Convention (SDIR = SIN V = O/E = 0)

As in the above sample start character, with the direct convention type, the logic 1 level corresponds to state Z and the logic 0 level to state A, and transfer is performed in LSB-first order. The start character data above is H'3B. For the direct convention type, clear the SDIR and SIN V bits in SCMR to 0. According to the Smart Card regulations, clear the O/E bit in SMR to 0 to select even parity mode.

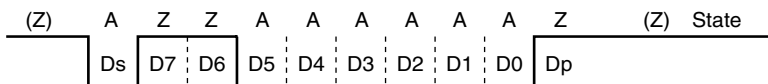

Figure 14.24 Inverse Convention (SDIR = SIN V = O/E = 1)

With the inverse convention type, the logic 1 level corresponds to state A and the logic 0 level to state Z, and transfer is performed in MSB-first order. The start character data above is H'3F. For the inverse convention type, set the SDIR and SIN V bits in SCMR to 1. According to the Smart Card regulations, even parity mode is the logic 0 level of the parity bit, and corresponds to state Z.

In this LSI, the SINV bit inverts only data bits D7 to D0. Therefore, set the O/ \bar{E} bit in SMR to 1 to invert the parity bit for both transmission and reception.

14.7.3 Block Transfer Mode

Operation in block transfer mode is the same as that in normal Smart Card interface, except for the following points.

- In reception, though the parity check is performed, no error signal is output even if an error is detected. However, the PER bit in SSR is set to 1 and must be cleared before receiving the parity bit of the next frame.
- In transmission, a guard time of at least 1 etu is left between the end of the parity bit and the start of the next frame.
- In transmission, because retransmission is not performed, the TEND flag is set to 1, 11.5 etu after transmission start.
- As with the normal Smart Card interface, the ERS flag indicates the error signal status, but since error signal transfer is not performed, this flag is always cleared to 0.

Note: etu: Elementary Time Unit (time for transfer of 1 bit)

14.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator is used as transmit/receive clock in Smart Card interface. In Smart Card interface mode, the SCI operates on a basic clock with a frequency of 32, 64, 372, or 256 times the bit rate (fixed at 16 times in normal asynchronous mode) as determined by bits BCP1 and BCP0. In reception, the SCI samples the falling edge of the start bit using the basic clock, and performs internal synchronization. As shown in figure 14.25, by sampling receive data at the rising-edge of the 16th, 32nd, 186th, or 128th pulse of the basic clock, data can be latched at the middle of the bit. The reception margin is given by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

Where M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, and 256)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5 and N = 372 in the above formula, the reception margin formula is as follows.

$$\begin{aligned} M &= (0.5 - 1/2 \times 372) \times 100\% \\ &= 49.866\% \end{aligned}$$

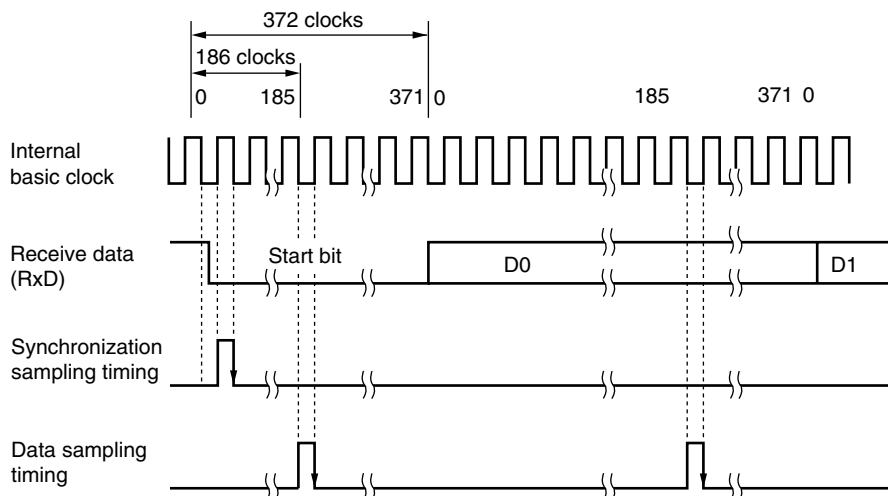

Figure 14.25 Receive Data Sampling Timing in Smart Card Mode
(Using Clock of 372 Times the Bit Rate)

14.7.5 Initialization

Before transmitting and receiving data, initialize the SCI as described below. Initialization is also necessary when switching from transmit mode to receive mode, or vice versa.

1. Clear the TE and RE bits in SCR to 0.
2. Clear the error flags ERS, PER, and ORER in SSR to 0.
3. Set the GM, BLK, O/\bar{E} , BCP1, BCP0, CKS1, and CKS0 bits in SMR. Set the PE bit to 1.
4. Set the SMIF, SDIR, and SINV bits in SCMR.

When the SMIF bit is set to 1, the TxD and RxD pins are both switched from ports to SCI pins, and are placed in the high-impedance state.

5. Set the value corresponding to the bit rate in BRR.
6. Set the CKE0 and CKE1 bits in SCR. Clear the TIE, RIE, TE, RE, MPIE, and TEIE bits to 0.
If the CKE0 bit is set to 1, the clock is output from the SCK pin.
7. Wait at least one bit interval, then set the TIE, RIE, TE, and RE bits in SCR. Do not set the TE bit and RE bit at the same time, except for self-diagnosis.

To switch from receive mode to transmit mode, after checking that the SCI has finished reception, initialize the SCI, and clear RE to 0 and set TE to 1. Whether SCI has finished reception can be checked with the RDRF, PER, or ORER flag. To switch from transmit mode to receive mode, after checking that the SCI has finished transmission, initialize the SCI, and clear TE to 0 and set RE to 1. Whether SCI has finished transmission can be checked with the TEND flag.

14.7.6 Data Transmission (Except for Block Transfer Mode)

As data transmission in Smart Card interface mode involves error signal sampling and retransmission processing, the operations are different from those in normal serial communication interface mode (except for block transfer mode). Figure 14.26 illustrates the retransfer operation when the SCI is in transmit mode.

1. If an error signal is sampled from the receiving end after transmission of one frame is completed, the ERS bit in SSR is set to 1. If the RIE bit in SCR is set at this time, an ERI interrupt request is generated. The ERS bit in SSR should be cleared to 0 before the next parity bit is sampled.
2. The TEND bit in SSR is not set for a frame for which an error signal is received. Data is retransferred from TDR to TSR, and retransmitted automatically.
3. If an error signal is not sent back from the receiving end, the ERS bit in SSR is not set.
4. Transmission of one frame, including a retransfer, is judged to have been completed, and the TEND bit in SSR is set to 1. If the TIE bit in SCR is set at this time, a TXI interrupt request is generated. Writing transmit data to TDR transfers the next transmit data.

Figure 14.28 shows a flowchart for transmission. The sequence of transmit operations can be performed automatically by specifying the DTC or DMAC* to be activated with a TXI interrupt source. In a transmit operation, the TDRE flag is also set to 1 at the same time as the TEND flag in SSR, and a TXI interrupt will be generated if the TIE bit in SCR has been set to 1. If the TXI request is designated beforehand as a DTC or DMAC* activation source, the DTC or DMAC* will be activated by the TXI request, and transfer of the transmit data will be carried out. The TDRE and TEND flags are automatically cleared to 0 when data transfer is performed by the DTC or DMAC*. In the event of an error, the SCI retransmits the same data automatically. During this period, the TEND flag remains cleared to 0 and the DTC or DMAC* is not activated. Therefore, the SCI and DTC or DMAC* will automatically transmit the specified number of bytes in the event of an error, including retransmission. However, the ERS flag is not cleared automatically when an error occurs, and so the RIE bit should be set to 1 beforehand so that an ERI request will be generated in the event of an error, and the ERS flag will be cleared.

When performing transfer using the DTC or DMAC*, it is essential to set and enable the DTC or DMAC* before carrying out SCI setting. For details on the DTC or DMAC setting procedures, refer to section 8, Data Transfer Controller (DTC) or section 7, DMA Controller (DMAC)*.

Note: * Not supported by the H8S/2366.

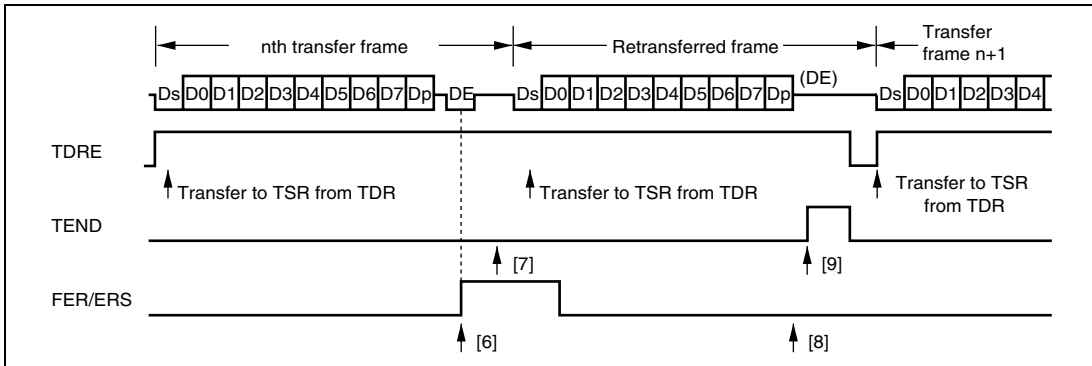

Figure 14.26 Retransfer Operation in SCI Transmit Mode

The timing for setting the TEND flag depends on the value of the GM bit in SMR. The TEND flag generation timing is shown in figure 14.27.

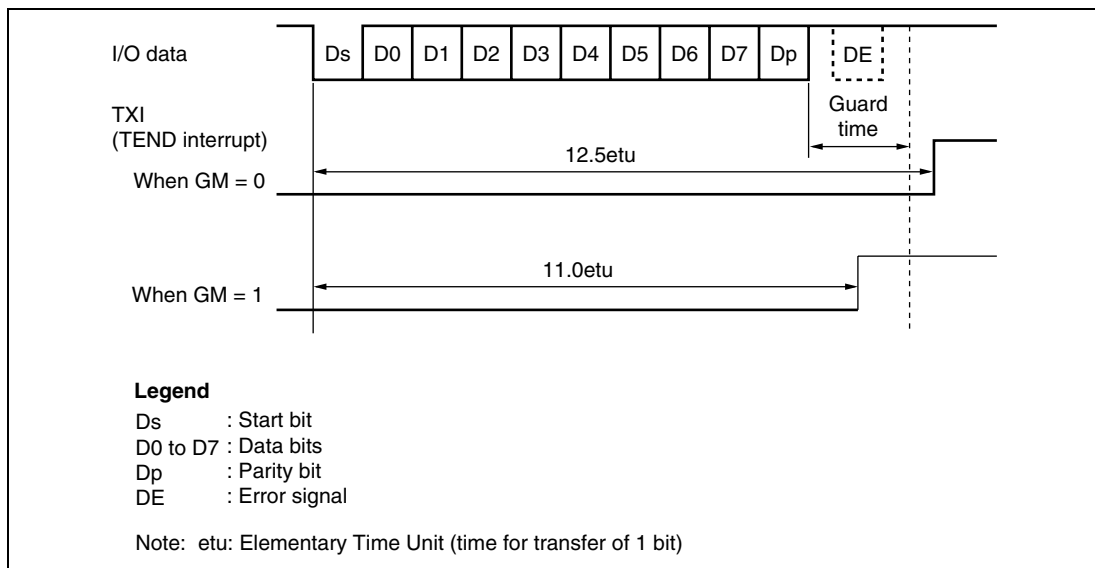

Figure 14.27 TEND Flag Generation Timing in Transmission Operation

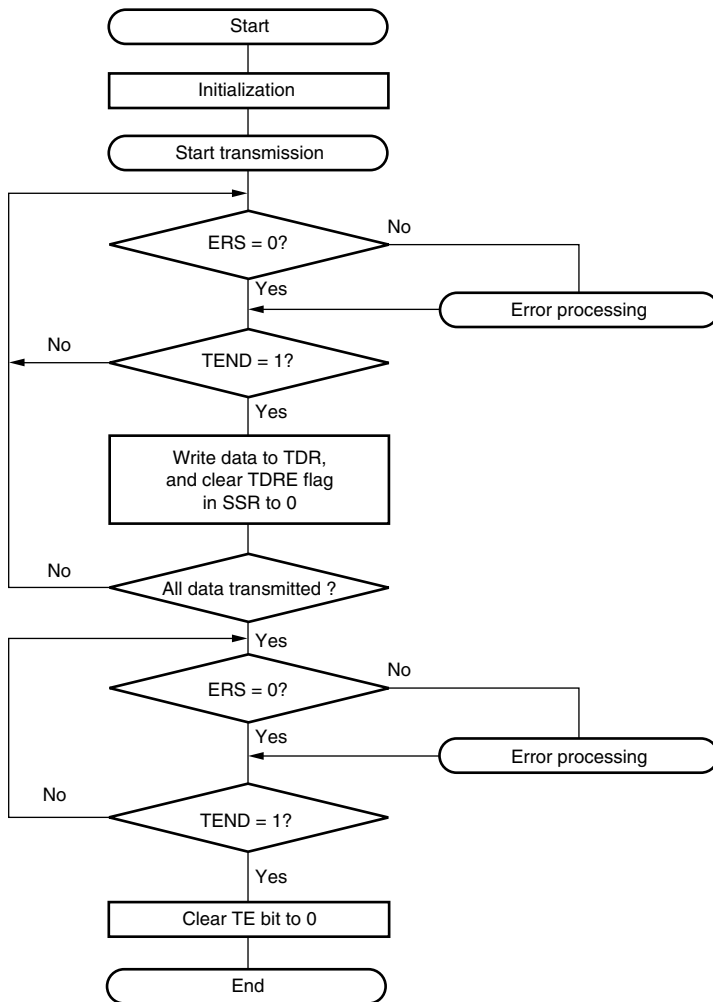

Figure 14.28 Example of Transmission Processing Flow

14.7.7 Serial Data Reception (Except for Block Transfer Mode)

Data reception in Smart Card interface mode uses the same operation procedure as for normal serial communication interface mode. Figure 14.29 illustrates the retransfer operation when the SCI is in receive mode.

1. If an error is found when the received parity bit is checked, the PER bit in SSR is automatically set to 1. If the RIE bit in SCR is set at this time, an ERI interrupt request is generated. The PER bit in SSR should be cleared to 0 before the next parity bit is sampled.
2. The RDRF bit in SSR is not set for a frame in which an error has occurred.
3. If no error is found when the received parity bit is checked, the PER bit in SSR is not set to 1.
4. The receive operation is judged to have been completed normally, and the RDRF flag in SSR is automatically set to 1. If the RIE bit in SCR is set at this time, an RXI interrupt request is generated.

Figure 14.30 shows a flowchart for reception. The sequence of receive operations can be performed automatically by specifying the DTC or DMAC* to be activated with an RXI interrupt source. In a receive operation, an RXI interrupt request is generated when the RDRF flag in SSR is set to 1. If the RXI request is designated beforehand as a DTC or DMAC* activation source, the DTC or DMAC* will be activated by the RXI request, and transfer of the receive data will be carried out. The RDRF flag is cleared to 0 automatically when data transfer is performed by the DTC or DMAC*. If an error occurs in receive mode and the ORER or PER flag is set to 1, a transfer error interrupt (ERI) request will be generated, and so the error flag must be cleared to 0. In the event of an error, the DTC or DMAC* is not activated and receive data is skipped. Therefore, receive data is transferred for only the specified number of bytes in the event of an error. Even when a parity error occurs in receive mode and the PER flag is set to 1, the data that has been received is transferred to RDR and can be read from there.

Notes: For details on receive operations in block transfer mode, refer to section 14.4, Operation in Asynchronous Mode.

* Not supported by the H8S/2366.

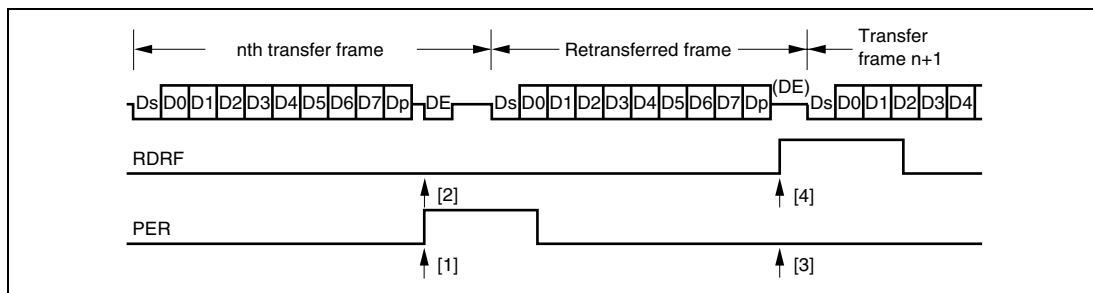

Figure 14.29 Retransfer Operation in SCI Receive Mode

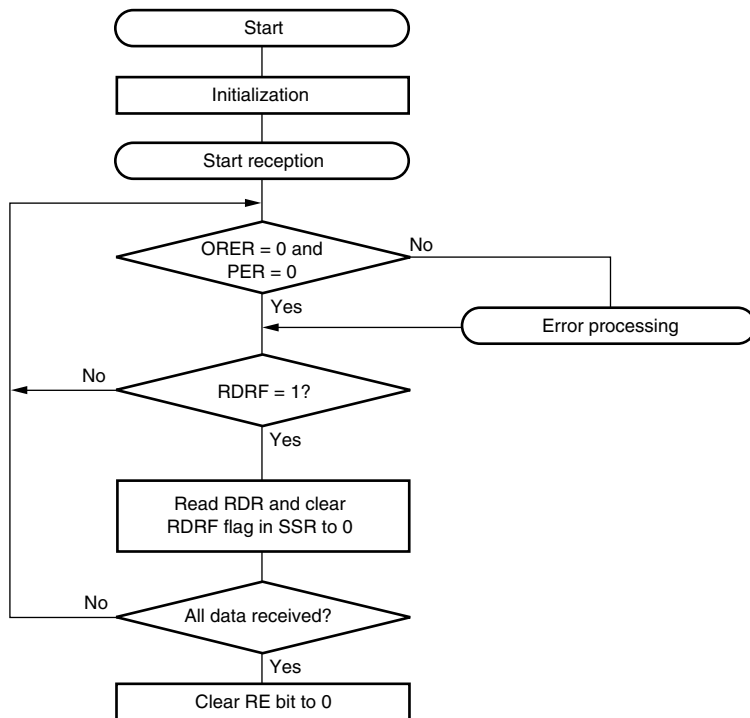

Figure 14.30 Example of Reception Processing Flow

14.7.8 Clock Output Control

When the GM bit in SMR is set to 1, the clock output level can be fixed with bits CKE1 and CKE0 in SCR. At this time, the minimum clock pulse width can be made the specified width.

Figure 14.31 shows the timing for fixing the clock output level. In this example, GM is set to 1, CKE1 is cleared to 0, and the CKE0 bit is controlled.

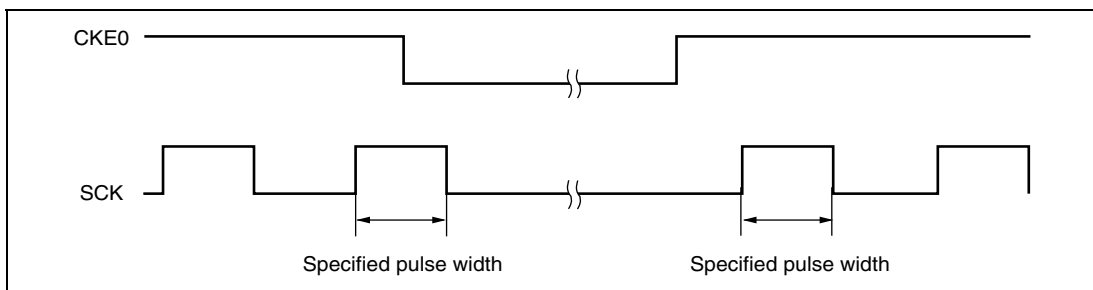

Figure 14.31 Timing for Fixing Clock Output Level

When turning on the power or switching between Smart Card interface mode and software standby mode, the following procedures should be followed in order to maintain the clock duty.

Powering On: To secure the clock duty from power-on, the following switching procedure should be followed.

1. The initial state is port input and high impedance. Use a pull-up resistor or pull-down resistor to fix the potential.
2. Fix the SCK pin to the specified output level with the CKE1 bit in SCR.
3. Set SMR and SCMR, and switch to smart card mode operation.
4. Set the CKE0 bit in SCR to 1 to start clock output.

When changing from smart card interface mode to software standby mode:

1. Set the data register (DR) and data direction register (DDR) corresponding to the SCK pin to the value for the fixed output state in software standby mode.
2. Write 0 to the TE bit and RE bit in the serial control register (SCR) to halt transmit/receive operation. At the same time, set the CKE1 bit to the value for the fixed output state in software standby mode.
3. Write 0 to the CKE0 bit in SCR to halt the clock.
4. Wait for one serial clock period.
During this interval, clock output is fixed at the specified level, with the duty preserved.
5. Make the transition to the software standby state.

When returning to smart card interface mode from software standby mode:

1. Exit the software standby state.
2. Write 1 to the CKE0 bit in SCR and output the clock. Signal generation is started with the normal duty.

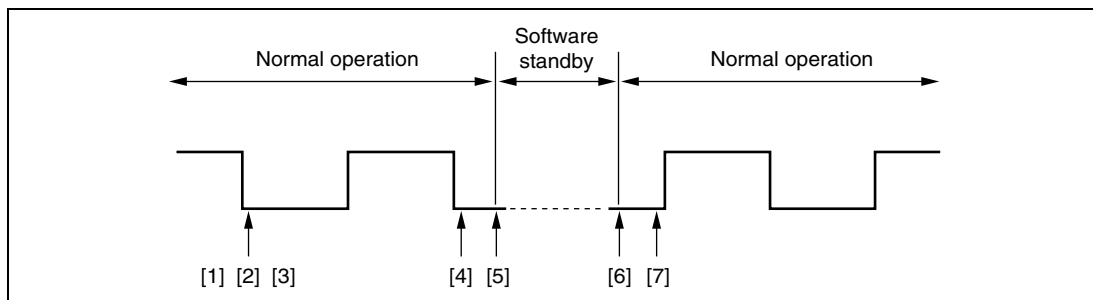

Figure 14.32 Clock Halt and Restart Procedure

14.8 IrDA Operation

When the IrDA function is enabled with bit IrE in IrCR, the SCI_0 TxD0 and RxD0 signals are subjected to waveform encoding/decoding conforming to IrDA specification version 1.0 (IrTxD and IrRxD pins). By connecting these pins to an infrared transceiver/receiver, it is possible to implement infrared transmission/reception conforming to the IrDA specification version 1.0 system.

In the IrDA specification version 1.0 system, communication is started at a transfer rate of 9600 bps, and subsequently the transfer rate can be varied as necessary. As the IrDA interface in this LSI does not include a function for varying the transfer rate automatically, the transfer rate setting must be changed by software.

Figure 14.33 shows a block diagram of the IrDA function.

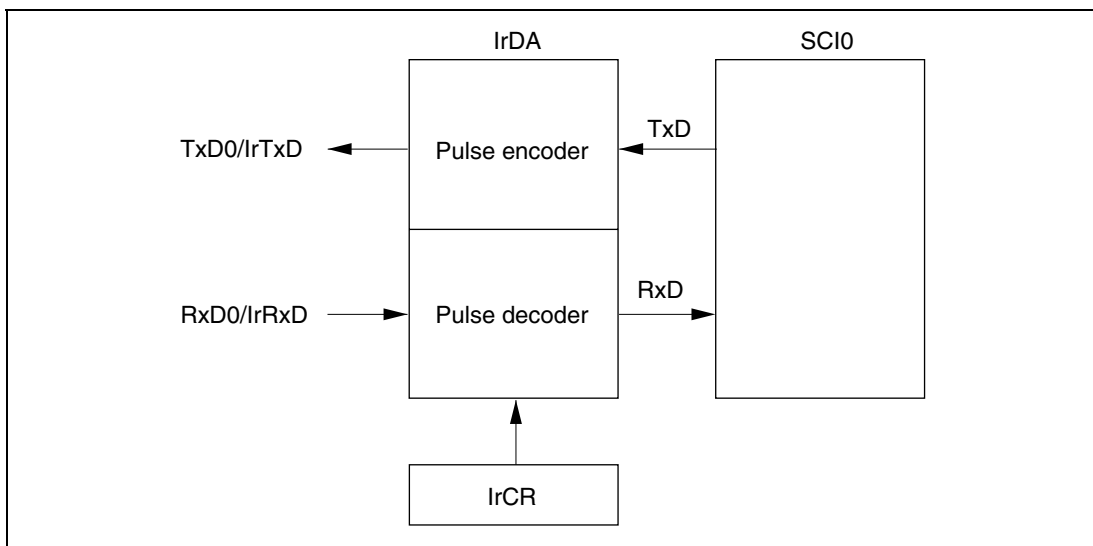

Figure 14.33 Block Diagram of IrDA

Transmission: In transmission, the output signal (UART frame) from the SCI is converted to an IR frame by the IrDA interface (see figure 14.34).

When the serial data is 0, a high pulse of 3/16 the bit rate (interval equivalent to the width of one bit) is output (initial value). The high-level pulse can be varied according to the setting of bits IrCKS2 to IrCKS0 in IrCR.

In the specification, the high pulse width is fixed at a minimum of 1.41 μ s, and a maximum of $(3/16 + 2.5\%) \times \text{bit rate}$ or $(3/16 \times \text{bit rate}) + 1.08 \mu$ s. When system clock ϕ is 20 MHz, 1.6 μ s can be set for a high pulse width with a minimum value of 1.41 μ s.

When the serial data is 1, no pulse is output.

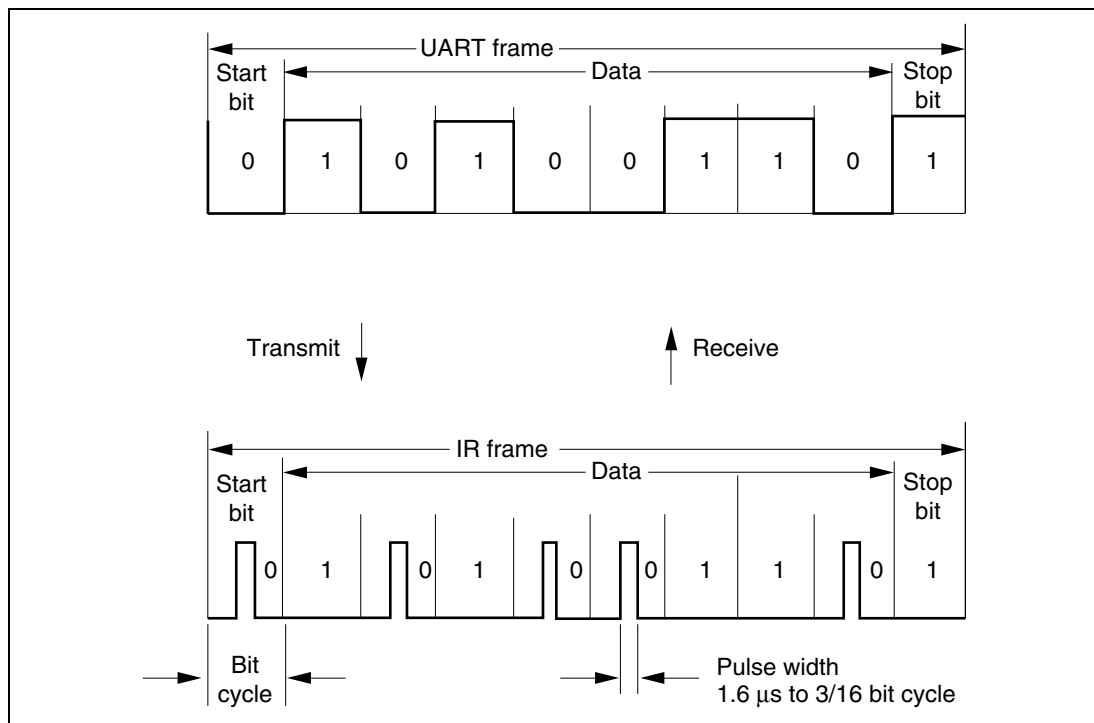

Figure 14.34 IrDA Transmit/Receive Operations

Reception: In reception, IR frame data is converted to a UART frame by the IrDA interface, and input to the SCI.

When a high pulse is detected, 0 data is output, and if there is no pulse during a one-bit interval, 1 data is output. Note that a pulse shorter than the minimum pulse width of 1.41 μ s will be identified as a 0 signal.

High Pulse Width Selection: Table 14.12 shows possible settings for bits IrCKS2 to IrCKS0 (minimum pulse width), and operating frequencies of this LSI and bit rates, for making the pulse width shorter than 3/16 times the bit rate in transmission.

Table 14.12 Settings of Bits IrCKS2 to IrCKS0

Operating Frequency ϕ (MHz)	Bit Rate (bps) (Above) /Bit Period \times 3/16 (μ s) (Below)					
	2400	9600	19200	38400	57600	115200

—: A bit rate setting cannot be made on the SCI side.

14.9 SCI Interrupts

14.9.1 Interrupts in Normal Serial Communication Interface Mode

Table 14.13 shows the interrupt sources in normal serial communication interface mode. A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled using the enable bits in SCR.

When the TDRE flag in SSR is set to 1, a TXI interrupt request is generated. When the TEND flag in SSR is set to 1, a TEI interrupt request is generated. A TXI interrupt can activate the DTC or DMAC* to perform data transfer. The TDRE flag is cleared to 0 automatically when data transfer is performed by the DTC or DMAC*.

When the RDRF flag in SSR is set to 1, an RXI interrupt request is generated. When the ORER, PER, or FER flag in SSR is set to 1, an ERI interrupt request is generated. An RXI interrupt request can activate the DTC or DMAC* to perform data transfer. The RDRF flag is cleared to 0 automatically when data transfer is performed by the DTC or DMAC*.

A TEI interrupt is generated when the TEND flag is set to 1 while the TEIE bit is set to 1. If a TEI interrupt and a TXI interrupt are generated simultaneously, the TXI interrupt has priority for acceptance. However, note that if the TDRE and TEND flags are cleared simultaneously by the TXI interrupt routine, the SCI cannot branch to the TEI interrupt routine later.

Note: * Not supported by the H8S/2366.

Table 14.13 SCI Interrupt Sources

Channel	Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC* Activation	Priority
0	ERI0	Receive Error	ORER, FER, PER	Not possible	Not possible	<div>High</div> <div>↑</div> <div>Low</div>
	RXI0	Receive Data Full	RDRF	Possible	Possible	
	TXI0	Transmit Data Empty	TDRE	Possible	Possible	
	TEI0	Transmission End	TEND	Not possible	Not possible	
1	ERI1	Receive Error	ORER, FER, PER	Not possible	Not possible	
	RXI1	Receive Data Full	RDRF	Possible	Possible	
	TXI1	Transmit Data Empty	TDRE	Possible	Possible	
	TEI1	Transmission End	TEND	Not possible	Not possible	
2	ERI2	Receive Error	ORER, FER, PER	Not possible	Not possible	
	RXI2	Receive Data Full	RDRF	Possible	Not possible	
	TXI2	Transmit Data Empty	TDRE	Possible	Not possible	
	TEI2	Transmission End	TEND	Not possible	Not possible	
3	ERI3	Receive Error	ORER, FER, PER	Not possible	Not possible	
	RXI3	Receive Data Full	RDRF	Possible	Not possible	
	TXI3	Transmit Data Empty	TDRE	Possible	Not possible	
	TEI3	Transmission End	TEND	Not possible	Not possible	
4	ERI4	Receive Error	ORER, FER, PER	Not possible	Not possible	
	RXI4	Receive Data Full	RDRF	Possible	Not possible	
	TXI4	Transmit Data Empty	TDRE	Possible	Not possible	
	TEI4	Transmission End	TEND	Not possible	Not possible	

Note: * Not supported by the H8S/2366.

14.9.2 Interrupts in Smart Card Interface Mode

Table 14.14 shows the interrupt sources in Smart Card interface mode. The transmit end interrupt (TEI) request cannot be used in this mode.

Table 14.14 Interrupt Sources

Channel	Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC* Activation	Priority
0	ERI0	Receive Error, detection	ORER, PER, ERS	Not possible	Not possible	 <div>High</div>
	RX10	Receive Data Full	RDRF	Possible	Possible	
	TX10	Transmit Data Empty	TEND	Possible	Possible	
1	ERI1	Receive Error, detection	ORER, PER, ERS	Not possible	Not possible	
	RX11	Receive Data Full	RDRF	Possible	Possible	
	TX11	Transmit Data Empty	TEND	Possible	Possible	
2	ERI2	Receive Error, detection	ORER, PER, ERS	Not possible	Not possible	
	RX12	Receive Data Full	RDRF	Possible	Not possible	
	TX12	Transmit Data Empty	TEND	Possible	Not possible	
3	ERI3	Receive Error, detection	ORER, PER, ERS	Not possible	Not possible	
	RX13	Receive Data Full	RDRF	Possible	Not possible	
	TX13	Transmit Data Empty	TEND	Possible	Not possible	
4	ERI4	Receive Error, detection	ORER, PER, ERS	Not possible	Not possible	
	RX14	Receive Data Full	RDRF	Possible	Not possible	
	TX14	Transmit Data Empty	TEND	Possible	Not possible	Low

Note: * Not supported by the H8S/2366.

In Smart Card interface mode, as in normal serial communication interface mode, transfer can be carried out using the DTC or DMAC*. In transmit operations, the TDRE flag is also set to 1 at the same time as the TEND flag in SSR, and a TXI interrupt is generated. If the TXI request is designated beforehand as a DTC or DMAC* activation source, the DTC or DMAC* will be activated by the TXI request, and transfer of the transmit data will be carried out. The TDRE and TEND flags are automatically cleared to 0 when data transfer is performed by the DTC or DMAC*. In the event of an error, the SCI retransmits the same data automatically. During this period, the TEND flag remains cleared to 0 and the DTC or DMAC* is not activated. Therefore, the SCI and DTC or DMAC* will automatically transmit the specified number of bytes in the event of an error, including retransmission. However, the ERS flag is not cleared automatically when an error occurs, and so the RIE bit should be set to 1 beforehand so that an ERI request will be generated in the event of an error, and the ERS flag will be cleared.

When performing transfer using the DTC or DMAC*, it is essential to set and enable the DTC or DMAC* before carrying out SCI setting. For details on the DTC or DMAC* setting procedures, refer to section 8, Data Transfer Controller (DTC) or section 7, DMA Controller (DMAC)*.

In receive operations, an RXI interrupt request is generated when the RDRF flag in SSR is set to 1. If the RXI request is designated beforehand as a DTC or DMAC* activation source, the DTC or DMAC* will be activated by the RXI request, and transfer of the receive data will be carried

out. The RDRF flag is cleared to 0 automatically when data transfer is performed by the DTC or DMAC*. If an error occurs, an error flag is set but the RDRF flag is not. Consequently, the DTC or DMAC* is not activated, but instead, an ERI interrupt request is sent to the CPU. Therefore, the error flag should be cleared.

Note: * Not supported by the H8S/2366.

14.10 Usage Notes

14.10.1 Module Stop Mode Setting

SCI operation can be disabled or enabled using the module stop control register. The initial setting is for SCI operation to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 22, Power-Down Modes.

14.10.2 Break Detection and Processing

When framing error detection is performed, a break can be detected by reading the RxD pin value directly. In a break, the input from the RxD pin becomes all 0s, and so the FER flag is set, and the PER flag may also be set. Note that, since the SCI continues the receive operation after receiving a break, even if the FER flag is cleared to 0, it will be set to 1 again.

14.10.3 Mark State and Break Sending

When TE is 0, the TxD pin is used as an I/O port whose direction (input or output) and level are determined by DR and DDR. This can be used to set the TxD pin to mark state or send a break during serial data transmission. To maintain the communication line at mark state until TE is set to 1, set both PCR and PDR to 1. Since TE is cleared to 0 at this point, the TxD pin becomes an I/O port, and 1 is output from the TxD pin. To send a break during serial transmission, first set PCR to 1 and clear PDR to 0, and then clear TE to 0. When TE is cleared to 0, the transmitter is initialized regardless of the current transmission state, the TxD pin becomes an I/O port, and 0 is output from the TxD pin.

14.10.4 Receive Error Flags and Transmit Operations (Clocked Synchronous Mode Only)

Transmission cannot be started when a receive error flag (ORER, PER, or FER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note also that receive error flags cannot be cleared to 0 even if the RE bit is cleared to 0.

14.10.5 Relation between Writes to TDR and the TDRE Flag

The TDRE flag in SSR is a status flag that indicates that transmit data has been transferred from TDR to TSR. When the SCI transfers data from TDR to TSR, the TDRE flag is set to 1.

Data can be written to TDR regardless of the state of the TDRE flag. However, if new data is written to TDR when the TDRE flag is cleared to 0, the data stored in TDR will be lost since it has not yet been transferred to TSR. It is therefore essential to check that the TDRE flag is set to 1 before writing transmit data to TDR.

14.10.6 Restrictions on Use of DMAC* or DTC

- When an external clock source is used as the serial clock, the transmit clock should not be input until at least five ϕ clock cycles after TDR is updated by the DMAC* or DTC. Abnormal operation may occur if the transmit clock is input within 4 ϕ clocks after TDR is updated. (figure 14.35)
- When RDR is read by the DMAC* or DTC, be sure to set the activation source to the relevant SCI receive-data-full interrupt (RXI).

Note: * Not supported by the H8S/2366.

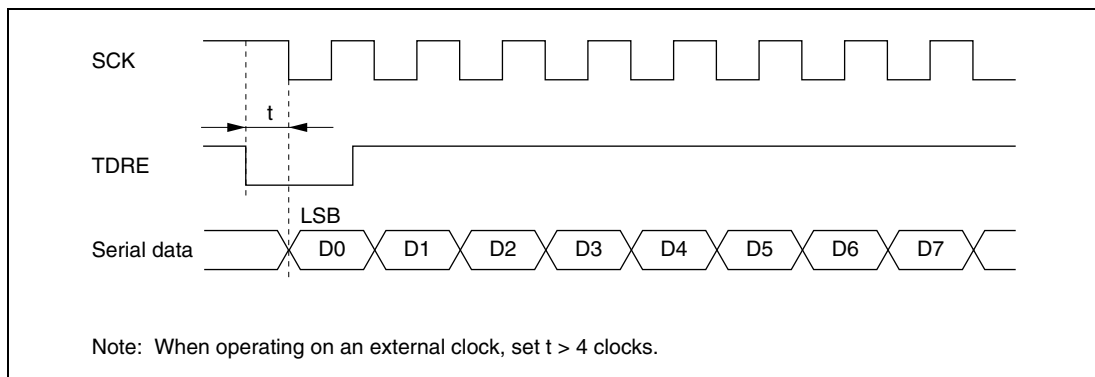

Figure 14.35 Example of Synchronous Transmission Using DTC

14.10.7 Operation in Case of Mode Transition

- Transmission

Operation should be stopped (by clearing TE, TIE, and TEIE to 0) before making a module stop mode or software standby mode transition. TSR, TDR, and SSR are reset. The output pin states in module stop mode or software standby mode depend on the port settings, and become high-level output after the relevant mode is cleared. If a transition is made during transmission, the data being transmitted will be undefined.

When transmitting without changing the transmit mode after the relevant mode is cleared, transmission can be started by setting TE to 1 again, and performing the following sequence: SSR read → TDR write → TDRE clearance. To transmit with a different transmit mode after clearing the relevant mode, the procedure must be started again from initialization.

Figure 14.36 shows a sample flowchart for mode transition during transmission. Port pin states during mode transition are shown in figures 14.37 and 14.38.

Operation should also be stopped (by clearing TE, TIE, and TEIE to 0) before making a transition from transmission by DTC transfer to module stop mode or software standby mode transition. To perform transmission with the DTC after the relevant mode is cleared, setting TE and TIE to 1 will set the TXI flag and start DTC transmission.

- Reception

Receive operation should be stopped (by clearing RE to 0) before making a module stop mode or software standby mode transition. RSR, RDR, and SSR are reset. If a transition is made during reception, the data being received will be invalid.

To continue receiving without changing the reception mode after the relevant mode is cleared, set RE to 1 before starting reception. To receive with a different receive mode, the procedure must be started again from initialization.

Figure 14.39 shows a sample flowchart for mode transition during reception.

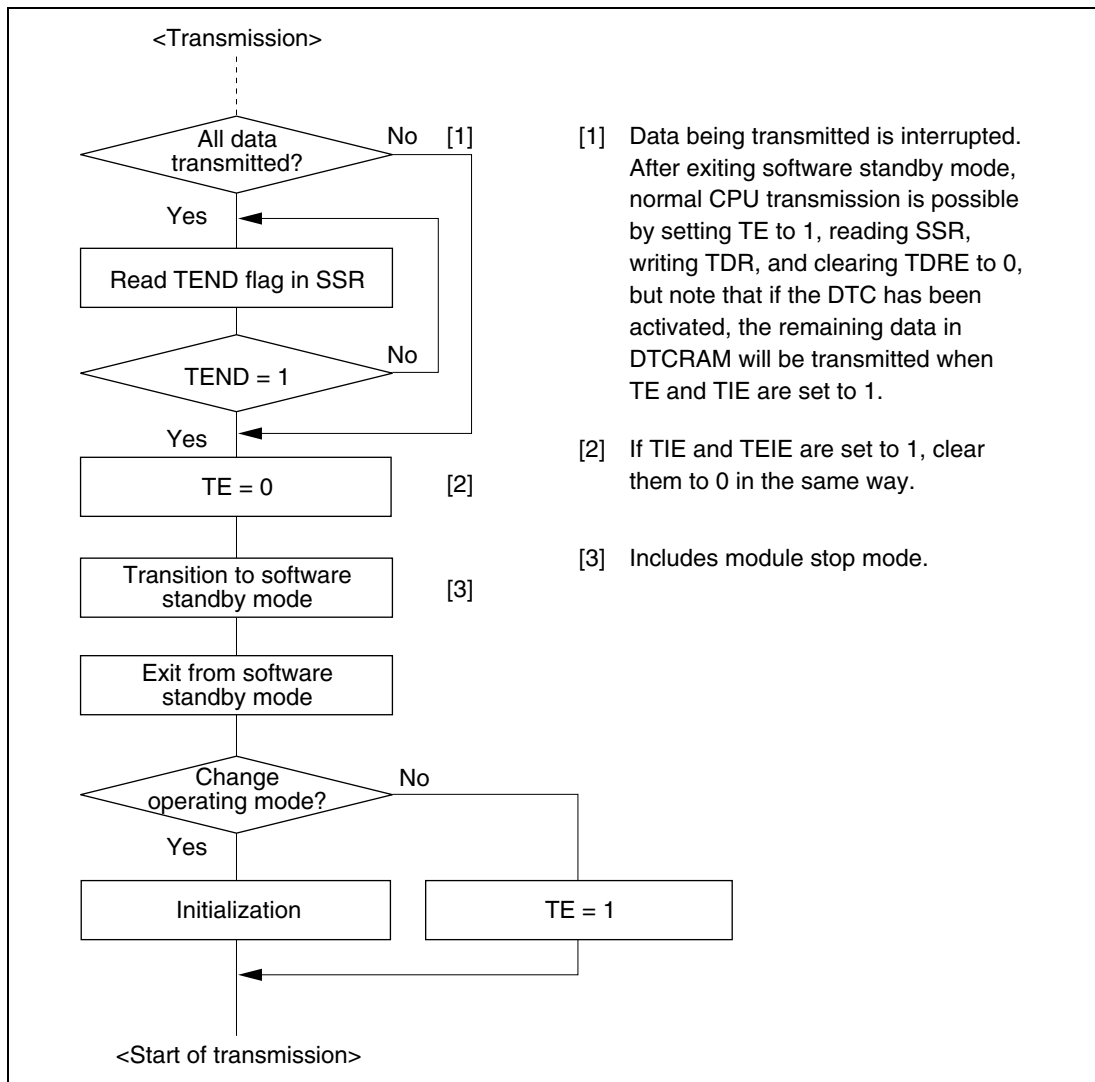

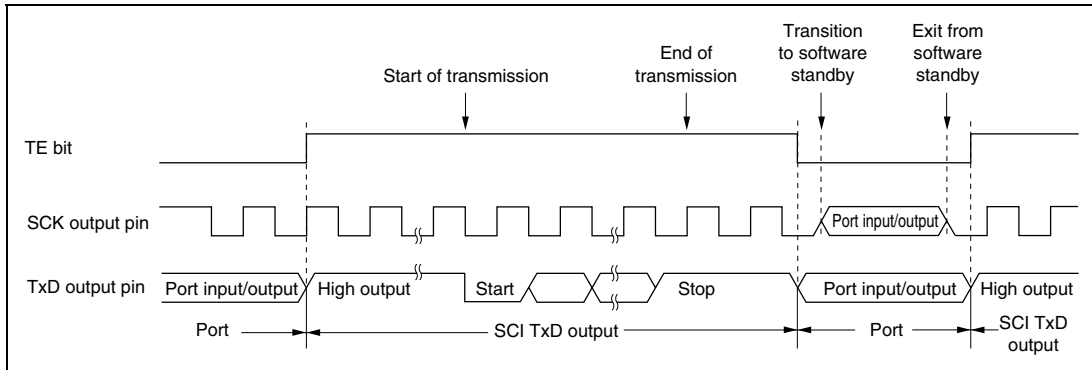

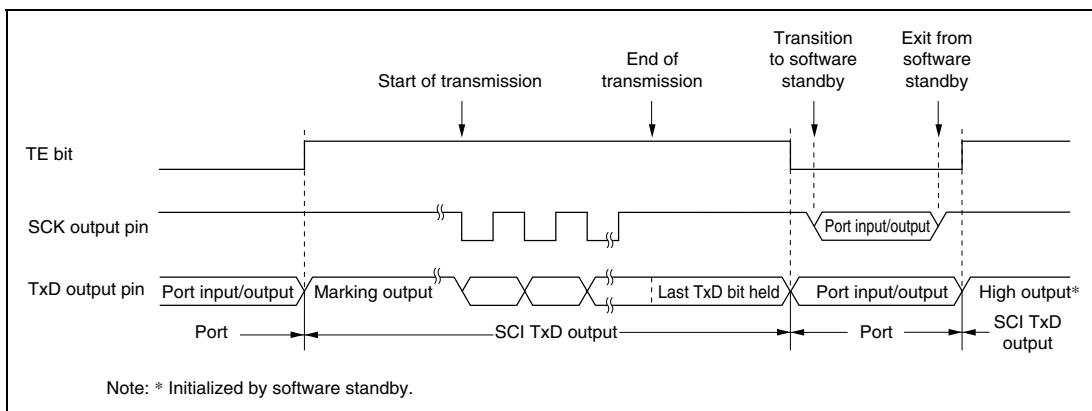

Figure 14.36 Sample Flowchart for Mode Transition during Transmission

**Figure 14.37 Port Pin States during Mode Transition
(Internal Clock, Asynchronous Transmission)**

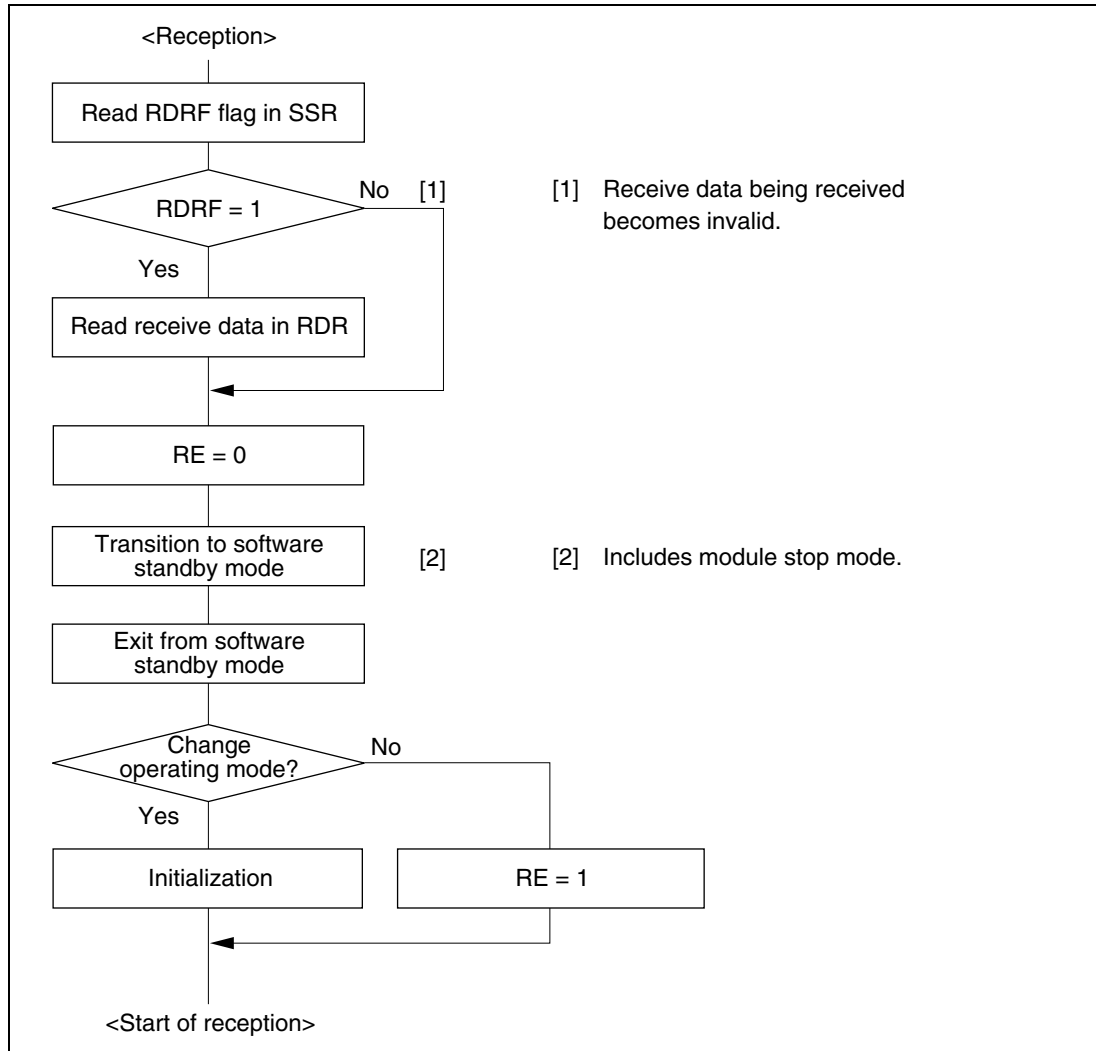

Figure 14.39 Sample Flowchart for Mode Transition during Reception

Section 15 I²C Bus Interface2 (IIC2) (Option)

An I²C bus interface is an option. When using the optional functions, take notice of the following items:

1. For the masked ROM version, 'W' is added to the model name of the product that uses optional functions.
For example: HD6432365WTE
2. For the F-ZTAT version, product model names do not depend on optional functions. When using optional functions, contact the Renesas Technology sales office.

This LSI has a two-channel I²C bus interface,

The I²C bus interface conforms to and provides a subset of the Philips I²C bus (inter-IC bus) interface functions. The register configuration that controls the I²C bus differs partly from the Philips configuration, however.

Figure 15.1 shows a block diagram of the I²C bus interface2.

Figure 15.2 shows an example of I/O pin connections to external circuits.

15.1 Features

- Continuous transmission/reception
Since the shift register, transmit data register, and receive data register are independent from each other, the continuous transmission/reception can be performed.
- Start and stop conditions generated automatically in master mode
- Selection of acknowledge output levels when receiving
- Automatic loading of acknowledge bit when transmitting
- Bit synchronization/wait function
In master mode, the state of SCL is monitored per bit, and the timing is synchronized automatically.
If transmission/reception is not yet possible, set the SCL to low until preparations are completed.
- Six interrupt sources
 - Transmit-data-empty (including slave-address match), transmit-end, receive-data-full (including slave-address match), arbitration lost, NACK detection, and stop condition detection
- Direct bus drive
 - Two pins, SCL and SDA pins function as NMOS open-drain outputs.

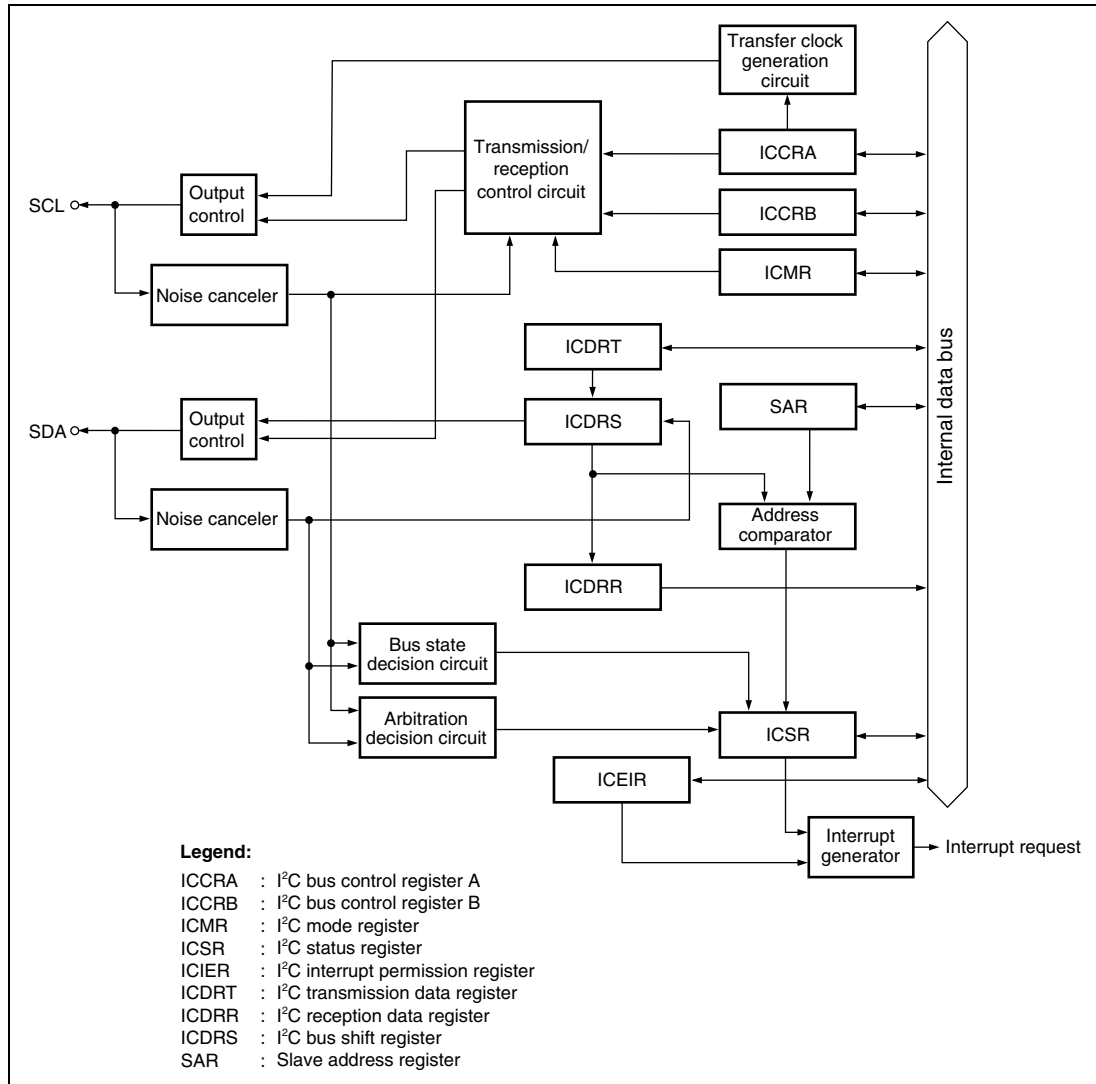

Figure 15.1 Block Diagram of I²C Bus Interface2

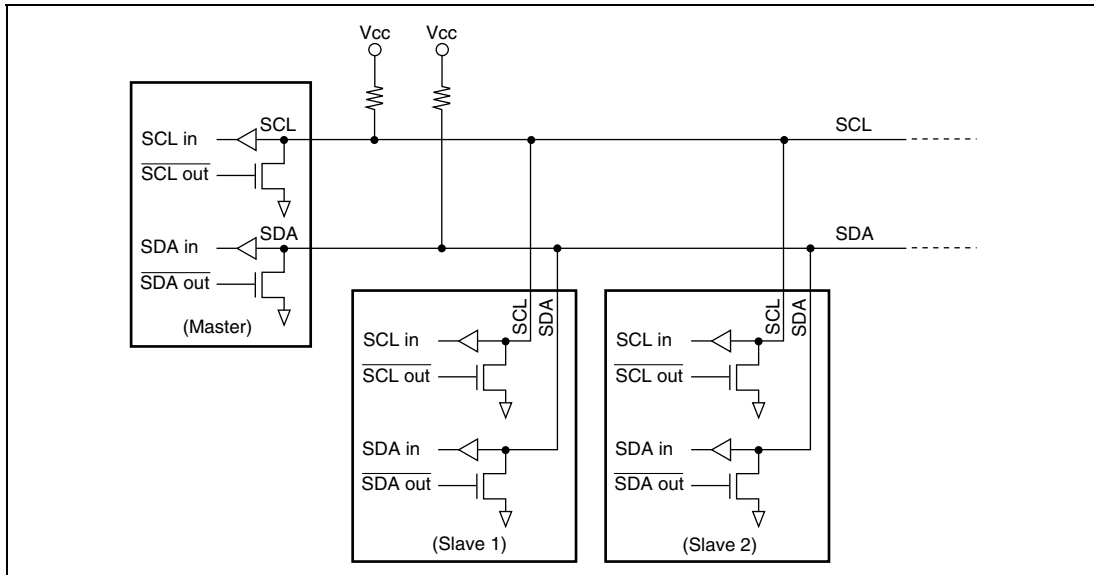

Figure 15.2 External Circuit Connections of I/O Pins

15.2 Input/Output Pins

Table 15.1 summarizes the input/output pins used by the I²C bus interface.

Table 15.1 Pin Configuration

Name	Abbreviation	I/O	Function
Serial clock	SCL0	I/O	IIC2_0 serial clock input/output
Serial data	SDA0	I/O	IIC2_0 serial data input/output
Serial clock	SCL1	I/O	IIC2_1 serial clock input/output
Serial data	SDA1	I/O	IIC2_1 serial data input/output

Note: The pin symbols are represented as SCL and SDA; channel numbers are omitted in this manual.

15.3 Register Descriptions

The I²C bus interface has the following registers.

- I²C bus control register A_0 (ICCRA_0)
- I²C bus control register B_0 (ICCRB_0)
- I²C bus mode register_0 (ICMR_0)
- I²C bus interrupt enable register_0 (ICIER_0)
- I²C bus status register_0 (ICSR_0)
- I²C bus slave address register_0 (SAR_0)
- I²C bus transmit data register_0 (ICDRT_0)
- I²C bus receive data register_0 (ICDRR_0)
- I²C bus shift register_0 (ICDRS_0)
- I²C bus control register A_1 (ICCRA_1)
- I²C bus control register B_1 (ICCRB_1)
- I²C bus mode register_1 (ICMR_1)
- I²C bus interrupt enable register_1 (ICIER_1)
- I²C bus status register_1 (ICSR_1)
- I²C bus slave address register_1 (SAR_1)
- I²C bus transmit data register_1 (ICDRT_1)
- I²C bus receive data register_1 (ICDRR_1)
- I²C bus shift register_1 (ICDRS_1)

15.3.1 I²C Bus Control Register A (ICCRA)

ICCRA is an 8-bit readable/writable register that enables or disables the I²C bus interface, controls transmission or reception, and selects master or slave mode, transmission or reception, and transfer clock frequency in master mode.

Bit	Bit Name	Initial Value	R/W	Description
7	ICE	0	R/W	I ² C Bus Interface Enable 0: This module is halted. 1: This bit is enabled for transfer operations. (SCL and SDA pins are bus drive state.)
6	RCVD	0	R/W	Reception Disable This bit enables or disables the next operation when TRS is 0 and ICDRR is read. 0: Enables next reception 1: Disables next reception
5	MST	0	R/W	Master/Slave Select
4	TRS	0	R/W	Transmit/Receive Select When arbitration is lost in master mode, MST and TRS are both reset by hardware, causing a transition to slave receive mode. Modification of the TRS bit should be made between transfer frames. Operating modes are described below according to MST and TRS combination. 00: Slave receive mode 01: Slave transmit mode 10: Master receive mode 11: Master transmit mode
3	CKS3	0	R/W	Transfer clock select 3 to 0
2	CKS2	0	R/W	These bits are valid only in master mode and should be set according to the necessary transfer rate. For details on transfer rate, see table 15.2.
1	CKS1	0	R/W	
0	CKS0	0	R/W	

Table 15.2 Transfer Rate

Bit3	Bit2	Bit1	Bit0	Clock	Transfer Rate				
CKS3	CKS2	CKS1	CKS0		$\phi=8\text{MHz}$	$\phi=10\text{MHz}$	$\phi=20\text{MHz}$	$\phi=25\text{MHz}$	$\phi=33\text{MHz}$
0	0	0	0	$\phi/28$	286kHz	357kHz	714kHz	893kHz	1179kHz
			1	$\phi/40$	200kHz	250kHz	500kHz	625kHz	825kHz
		1	0	$\phi/48$	167kHz	208kHz	417kHz	521kHz	688kHz
			1	$\phi/64$	125kHz	156kHz	313kHz	391kHz	516kHz
	1	0	0	$\phi/168$	47.6kHz	59.5kHz	119kHz	149kHz	196kHz
			1	$\phi/100$	80.0kHz	100kHz	200kHz	250kHz	330kHz
		1	0	$\phi/112$	71.4kHz	89.3kHz	179kHz	223kHz	295kHz
			1	$\phi/128$	62.5kHz	78.1kHz	156kHz	195kHz	258kHz
1	0	0	0	$\phi/56$	143kHz	179kHz	357kHz	446kHz	589kHz
			1	$\phi/80$	100kHz	125kHz	250kHz	313kHz	413kHz
		1	0	$\phi/96$	83.3kHz	104kHz	208kHz	260kHz	344kHz
			1	$\phi/128$	62.5kHz	78.1kHz	156kHz	195kHz	258kHz
	1	0	0	$\phi/336$	23.8kHz	29.8kHz	59.5kHz	74.4kHz	98.2kHz
			1	$\phi/200$	40.0kHz	50.0kHz	100kHz	125kHz	165kHz
		1	0	$\phi/224$	35.7kHz	44.6kHz	89.3kHz	112kHz	147kHz
			1	$\phi/256$	31.3kHz	39.1kHz	78.1kHz	97.7kHz	129kHz

15.3.2 I²C Bus Control Register B (ICCRB)

ICCRB is an 8-bit readable/writable register that issues start/stop conditions, manipulates the SDA pin, monitors the SCL pin, and controls reset in I²C control.

Bit	Bit Name	Initial Value	R/W	Description
7	BBSY	0	R/W	<p>Bus Busy</p> <p>This bit enables to confirm whether the I²C bus is occupied or released and to issue start and stop conditions in master mode. This bit is set to 1 when the SDA level changes from high to low under the condition of SCL = high, assuming that the start condition has been issued. This bit is cleared to 0 when the SDA level changes from low to high under the condition of SCL = high, assuming that the stop condition has been issued. Write 1 to BBSY and 0 to SCP to issue a start condition. Follow this procedure when also re-transmitting a start condition. Write 0 to BBSY and 0 to SCP to issue a stop condition. To issue a start/stop condition, use the MOV instruction.</p>

Bit	Bit Name	Initial Value	R/W	Description
6	SCP	1	W	<p>Start Condition/Stop Condition Prohibit</p> <p>The SCP bit controls the issue of start/stop conditions in master mode.</p> <p>To issue a start condition, write 1 in BBSY and 0 in SCP. A retransmit start condition is issued in the same way. To issue a stop condition, write 0 in BBSY and 0 in SCP. This bit is always read as 1. If 1 is written, the data is not stored.</p>
5	SDAO	1	R/W	<p>Monitors the output level of SDA.</p> <p>0: When reading, SDA pin outputs low.</p> <p>1: When reading, SDA pin outputs high.</p> <p>The write value should always be 1.</p>
4	—	1	R/W	<p>Reserved</p> <p>The write value should always be 1.</p>
3	SCLO	1	R	<p>This bit monitors SCL output level. When reading and SCLO is 1, SCL pin outputs high. When reading and SCLO is 0, SCL pin outputs low.</p>
2	—	1	—	<p>Reserved</p> <p>This bit is always read as 1.</p>
1	IICRST	0	R/W	<p>IIC control part reset</p> <p>This bit resets control parts except for I²C registers. If this bit is set to 1 when hang-up is occurred because of communication failure during I²C operation, I²C control part can be reset without setting ports and initializing registers.</p>
0	—	1	—	<p>Reserved</p> <p>This bit is always read as 1.</p>

15.3.3 I²C Bus Mode Register (ICMR)

ICMR is an 8-bit readable/writable register that selects whether the MSB or LSB is transferred first, performs master mode wait control, and selects the transfer bit count.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R/W	Reserved The write value should always be 0.
6	WAIT	0	R/W	Wait Insertion Bit This bit selects whether to insert a wait after data transfer except for the acknowledge bit. When WAIT is set to 1, after the fall of the clock for the final data bit, low period is extended for two transfer clocks. If WAIT is cleared to 0, data and acknowledge bits are transferred consecutively with no wait inserted. The setting of this bit is invalid in slave mode.
5	—	1	—	Reserved
4	—	1	—	These bits are always read as 1.
3	BCWP	1	R/W	BC Write Protect This bit controls the BC2 to BC0 modifications. When modifying BC2 to BC0, this bit should be cleared to 0 and use the MOV instruction. 0: When writing, values of BC2 to BC0 are set. 1: When reading, 1 is always read. When writing, settings of BC2 to BC0 are invalid.

Bit	Bit Name	Initial Value	R/W	Description
2	BC2	0	R/W	Bit Counter 2 to 0
1	BC1	0	R/W	These bits specify the number of bits to be transferred next.
0	BC0	0	R/W	When read, the remaining number of transfer bits is indicated. The data is transferred with one addition acknowledge bit. Bit BC2 to BC0 settings should be made during an interval between transfer frames. If bits BC2 to BC0 are set to a value other than 000, the setting should be made while the SCL line is low. The value returns to 000 at the end of a data transfer, including the acknowledge bit. With the clock synchronous serial format, these bits should not be modified.
				000: 9
				001: 2
				010: 3
				011: 4
				100: 5
				101: 6
				110: 7
				111: 8

15.3.4 I²C Bus Interrupt Enable Register (ICIER)

ICIER is an 8-bit readable/writable register that enables or disables interrupt sources and acknowledge bits, sets acknowledge bits to be transferred, and confirms acknowledge bits to be received.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	Transmit Interrupt Enable When the TDRE bit in ICSR is set to 1, this bit enables or disables the transmit data empty interrupt (TXI). 0: Transmit data empty interrupt request (TXI) is disabled. 1: Transmit data empty interrupt request (TXI) is enabled.
6	TEIE	0	R/W	Transmit End Interrupt Enable This bit enables or disables the transmit end interrupt (TEI) at the rising of the ninth clock while the TDRE bit in ICSR is 1. TEI can be canceled by clearing the TEND bit or the TEIE bit to 0. 0: Transmit end interrupt request (TEI) is disabled. 1: Transmit end interrupt request (TEI) is enabled.

Bit	Bit Name	Initial Value	R/W	Description
5	RIE	0	R/W	<p>Receive interrupt enable</p> <p>This bit enables or disables the receive data full interrupt request (RXI) when a received data is transferred from ICDRS to ICDRR and the RDRF bit in ICSR is set to 1. RXI can be canceled by clearing the RDRF or RIE bit to 0.</p> <p>0: Receive data full interrupt request (RXI) is disabled.</p> <p>1: Receive data full interrupt request (RXI) is enabled.</p>
4	NAKIE	0	R/W	<p>NACK receive interrupt enable</p> <p>This bit enables or disables the NACK receive interrupt request (NAKI) when the NACKF and AL bits in ICSR are set to 1. NAKI can be canceled by clearing the NACKF, AL, or NAKIE bit to 0.</p> <p>0: NACK receive interrupt request (NAKI) is disabled.</p> <p>1: NACK receive interrupt request (NAKI) is enabled.</p>
3	STIE	0	R/W	<p>Stop condition detection interrupt enable</p> <p>0: Stop condition detection interrupt request (STPI) is disabled.</p> <p>1: Stop condition detection interrupt request (STPI) is enabled.</p>
2	ACKE	0	R/W	<p>Acknowledge Bit Judgement Select</p> <p>0: The value of the acknowledge bit is ignored, and continuous transfer is performed.</p> <p>1: If the acknowledge bit is 1, continuous transfer is interrupted.</p>
1	ACKBR	0	R	<p>Receive acknowledge</p> <p>In transmit mode, this bit stores the acknowledge data that are returned by the receive device. This bit cannot be modified.</p> <p>0: Receive acknowledge = 0</p> <p>1: Receive acknowledge = 1</p>
0	ACKBT	0	R/W	<p>Transmit acknowledge</p> <p>In receive mode, this bit specifies the bit to be sent at the acknowledge timing.</p> <p>0: 0 is sent at the acknowledge timing.</p> <p>1: 1 is sent at the acknowledge timing.</p>

15.3.5 I²C Bus Status Register (ICSR)

ICSR is an 8-bit readable/writable register that performs confirmation of interrupt request flags and status.

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	0	R/W	<p>Transmit Data Register Empty</p> <p>[Setting condition]</p> <p>When data is transferred from ICDRT to ICDRS and ICDRT becomes empty</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When 0 is written in TDRE after reading TDRE = 1• When data is written to ICDRT
6	TEND	0	R/W	<p>Transmit end</p> <p>[Setting condition]</p> <p>When the ninth clock of SCL is rose while the TDRE flag is 1</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When 0 is written in TEND after reading TEND = 1• When data is written to ICDRT
5	RDRF	0	R/W	<p>Receive Data Register Full</p> <p>[Setting condition]</p> <p>When a received data is transferred from ICDRS to ICDRR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When 0 is written in RDRF after reading RDRF = 1• When ICDRR is read
4	NACKF	0	R/W	<p>No acknowledge detection flag</p> <p>[Setting condition]</p> <p>When no acknowledge is detected from the receive device in transmission while the ACKF bit in ICIER is 1</p> <p>[Clearing condition]</p> <p>When 0 is written in NACKF after reading NACKF = 1</p>

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	0	R/W	<p>Stop condition detection flag</p> <p>[Setting condition]</p> <p>When a stop condition is detected after frame transfer</p> <p>[Clearing condition]</p> <p>When 0 is written in STOP after reading STOP = 1</p>
2	AL	0	R/W	<p>Arbitration Lost Flag</p> <p>This flag indicates that arbitration was lost in master mode.</p> <p>When two or more master devices attempt to seize the bus at nearly the same time, if the I²C bus interface detects data differing from the data it sent, it sets AL to 1 to indicate that the bus has been taken by another master.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> • If the internal SDA and SDA pin disagree at the rise of SCL in master transmit mode • When the SDA pin outputs high in master mode while a start condition is detected <p>[Clearing condition]</p> <p>When 0 is written in AL/OVE after reading AL/OVE=1</p>
1	AAS	0	R/W	<p>Slave Address Recognition Flag</p> <p>In slave receive mode, this flag is set to 1 if the first frame following a start condition matches bits SVA6 to SVA0 in SAR.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> • When the slave address is detected in slave receive mode • When the general call address is detected in slave receive mode. <p>[Clearing condition]</p> <p>When 0 is written in AAS after reading AAS=1</p>
0	ADZ	0	R/W	<p>General Call Address Recognition Flag</p> <p>This bit is valid in slave receive mode.</p> <p>[Setting condition]</p> <p>When the general call address is detected in slave receive mode</p> <p>[Clearing conditions]</p> <p>When 0 is written in ADZ after reading ADZ=1</p>

15.3.6 Slave Address Register (SAR)

SAR is an 8-bit readable/writable register that sets slave address. When the chip is in slave mode, if the upper 7 bits of SAR match the upper 7 bits of the first frame received after a start condition, the chip operates as the slave device.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	SVA6 to SVA0	0	R/W	Slave Address 6 to 0 These bits set a unique address in bits SVA6 to SVA0, differing from the addresses of other slave devices connected to the I ² C bus.
0	—	0	R/W	Reserved Though this bit can be read from or written to, the write value should always be 0.

15.3.7 I²C Bus Transmit Data Register (ICDRT)

ICDRT is an 8-bit readable/writable register that stores the transmit data. When ICDRT detects the space in the I²C bus shift register (ICDRS), it transfers the transmit data which is written in ICDRT to ICDRS and starts transferring data. If the next transfer data is written to ICDRT during transferring data of ICDRS, continuous transfer is possible.

15.3.8 I²C Bus Receive Data Register (ICDRR)

ICDRR is an 8-bit register that stores the receive data. When data of one byte is received, ICDRR transfers the received data from ICDRS to ICDRR and the next data can be received. ICDRR is a receive-only register, therefore the CPU cannot be written to this register.

15.3.9 I²C Bus Shift Register (ICDRS)

ICDRS is a register that is used to transfer/receive data. In transmission, data is transferred from ICDRT to ICDRS and the data is sent from the SDA pin. In reception, data is transferred from ICDRS to ICDRR after data of one byte is received. This register cannot be read from the CPU.

15.4 Operation

15.4.1 I²C Bus Format

Figure 15.3 shows the I²C bus formats. Figure 15.4 shows the I²C bus timing. The first frame following a start condition always consists of 8 bits.

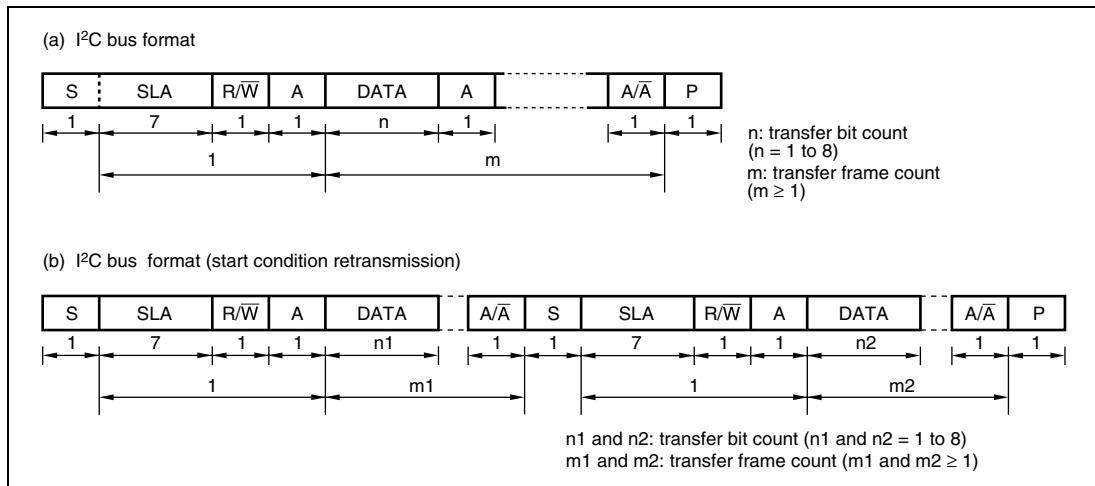

Figure 15.3 I²C Bus Formats

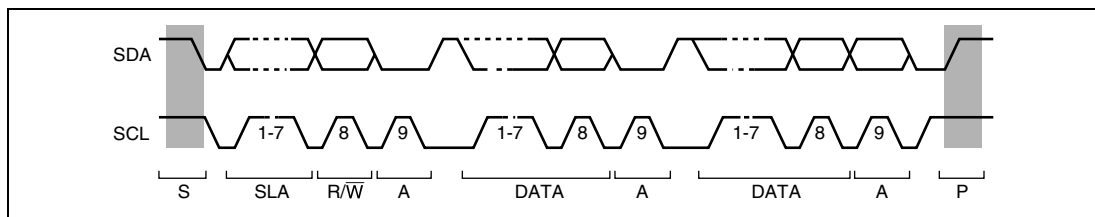

Figure 15.4 I²C Bus Timing

Legend

S: Start condition. The master device drives SDA from high to low while SCL is high.

SLA: Slave address

R/\overline{W} : Indicates the direction of data transfer: from the slave device to the master device when R/\overline{W} is 1, or from the master device to the slave device when R/\overline{W} is 0.

A: Acknowledge. The receiving device drives SDA to low.

DATA: Transferred data

P: Stop condition. The master device drives SDA from low to high while SCL is high.

15.4.2 Master Transmit Operation

In I²C bus format master transmit mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For master transmit mode operation timing, refer to figures 15.5 and 15.6. The transmission procedure and operations in master transmit mode are described below.

1. Set the ICE bit in ICCRA to 1. Set the WAIT bit in ICMR and the CKS3 to CKS0 bits in ICCR1 to 1. (Initial setting)
2. Read the BBSY flag in ICCRB to confirm that the bus is free. Set the MST and TRS bits in ICCRA to select master transmit mode. Then, write 1 to BBSY and 0 to SCP using MOV instruction. (Start condition issued) This generates the start condition.
3. After confirming that TDRE in ICSR has been set, write the transmit data (the first byte data show the slave address and R/\overline{W}) to ICDRT. After this, when TDRE is cleared to 0, data is transferred from ICDRT to ICDRS. TDRE is set again.
4. When transmission of one byte data is completed while TDRE is 1, TEND in ICSR is set to 1 at the rise of the 9th transmit clock pulse. Read the ACKBR bit in ICIER, and confirm that the slave device has been selected. Then, write second byte data to ICDRT, and clear TDRE and TEND. When ACKBR is 1, the slave device has not been acknowledged, so issue the stop condition. To issue the stop condition, write 0 to BBSY and SCP using MOV instruction. SCL is fixed low until the transmit data is prepared or the stop condition is issued.
5. The transmit data after the second byte is written to ICDRT every time TDRE is set, thus clearing TDRE.
6. Write the number of bytes to be transmitted to ICDRT. Wait until TEND is set (the end of last byte data transmission) while TDRE is 1, or wait for NACK (NACKF in ICSR = 1) from the receive device while ACKF in ICIER is 1. Then, issue the stop condition to clear TEND or NACKF.
7. When the STOP bit in ICSR is set to 1, the operation returns to the slave receive mode.

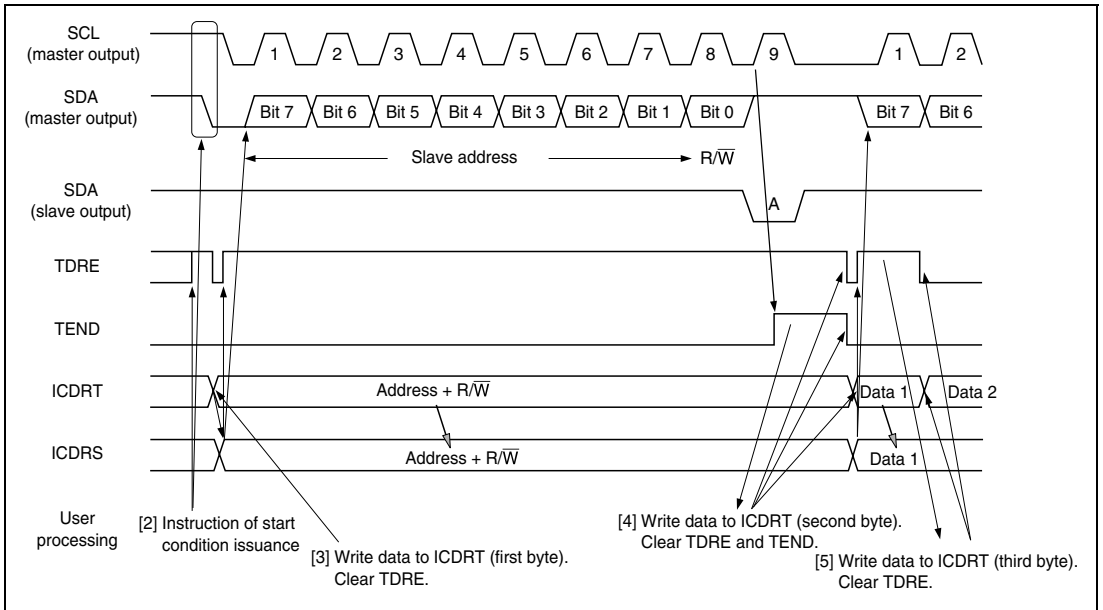

Figure 15.5 Master Transmit Mode Operation Timing 1

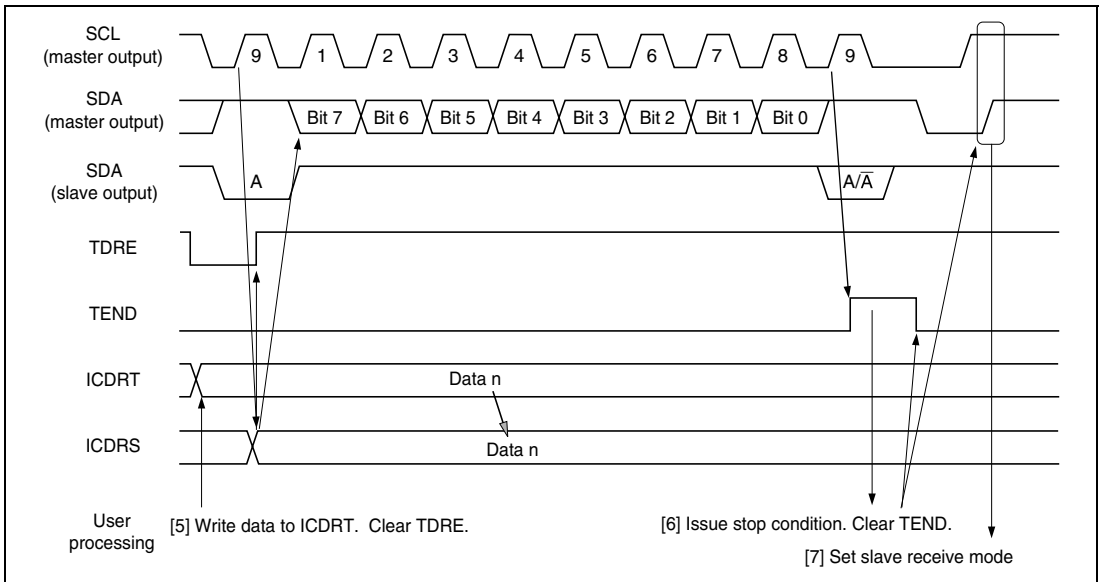

Figure 15.6 Master Transmit Mode Operation Timing 2

15.4.3 Master Receive Operation

In master receive mode, the master device outputs the receive clock, receives data from the slave device, and returns an acknowledge signal. For master receive mode operation timing, refer to figures 15.7 and 15.8. The reception procedure and operations in master receive mode are shown below.

1. Clear the TEND bit in ICSR to 0, then clear the TRS bit in ICCRA to 0 to switch from master transmit mode to master receive mode. Then, clear the TDRE bit to 0.
2. When ICDRR is read (dummy data read), reception is started, and the receive clock is output, and data received, in synchronization with the internal clock. The master device outputs the level specified by ACKBT in ICIER to SDA, at the 9th receive clock pulse.
3. After the reception of first frame data is completed, the RDRF bit in ICST is set to 1 at the rise of 9th receive clock pulse. At this time, the received data is read by reading ICDRR.
4. The continuous reception is performed by reading ICDRR and clearing RDRF to 0 every time RDRF is set. If 8th receive clock pulse falls after reading ICDRR by the other processing while RDRF is 1, SCL is fixed low until ICDRR is read.
5. If next frame is the last receive data, set the RCVD bit in ICCR1 to 1 before reading ICDRR. This enables the issuance of the stop condition after the next reception.
6. When the RDRF bit is set to 1 at rise of the 9th receive clock pulse, read ICDRR. Then, clear RCVD.
7. When the STOP bit in ICSR is set to 1, read ICDRR and clear RDRF to 0. Then clear the RCVD bit to 0.
8. The operation returns to the slave receive mode.

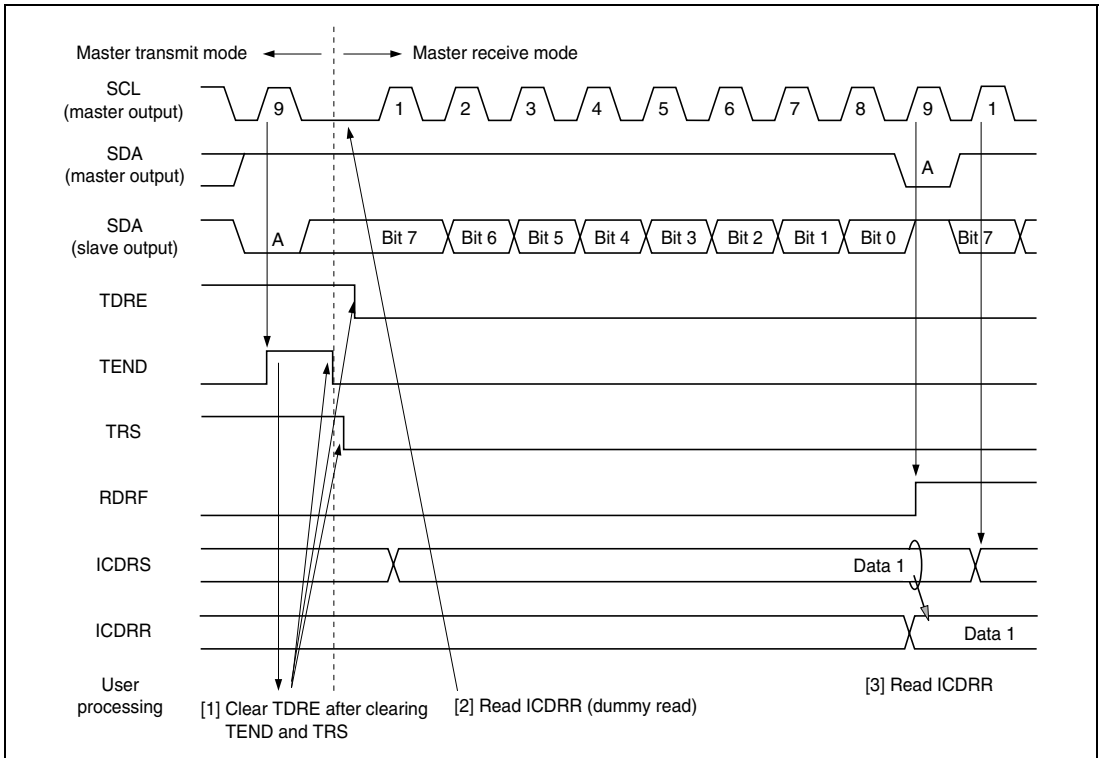

Figure 15.7 Master Receive Mode Operation Timing 1

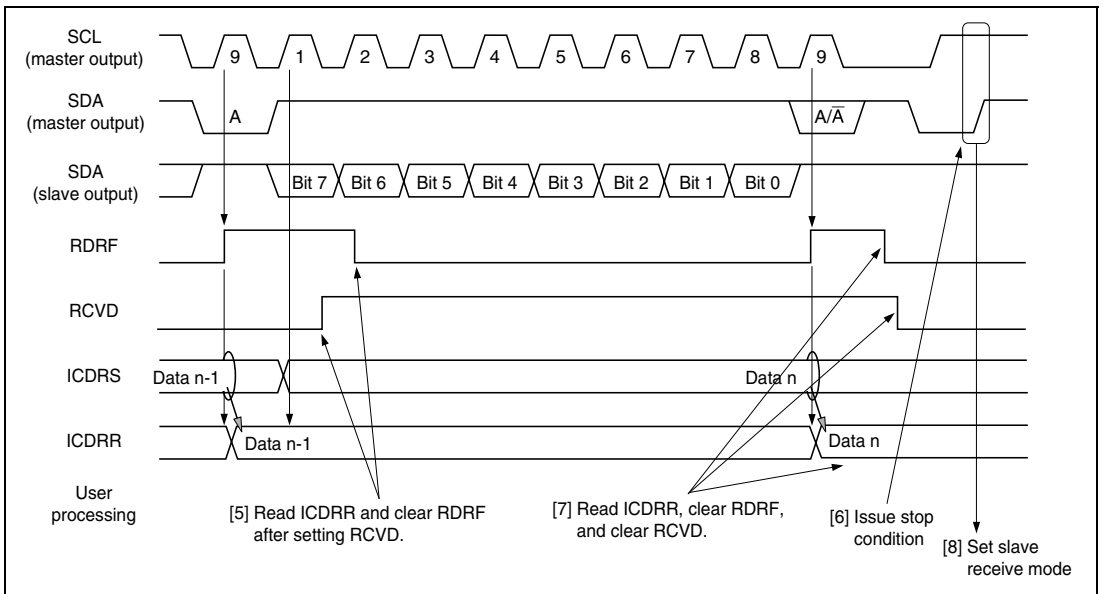

Figure 15.8 Master Receive Mode Operation Timing 2

15.4.4 Slave Transmit Operation

In slave transmit mode, the slave device outputs the transmit data, while the master device outputs the receive clock and returns an acknowledge signal. For slave transmit mode operation timing, refer to figures 15.9 and 15.10.

The transmission procedure and operations in slave transmit mode are described below.

1. Set the ICE bit in ICCRA to 1. Set the MLS and WAIT bits in ICMR and the CKS3 to CKS0 bits in ICCRA to 1. (Initial setting) Set the MST and TRS bits in ICCRA to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At this time, if the 8th bit data (R/\overline{W}) is 1, the TRS in ICCRA and TDRE in ICSR are set to 1, and the mode changes to slave transmit mode automatically. The continuous transmission is performed by clearing TDRE after writing transmit data to ICDRT every time TDRE is set.
3. If TDRE is set after writing last transmit data to ICDRT, wait until TEND in ICSR is set to 1, with TDRE = 1. When TEND is set, clear TEND.
4. Clear TRS for the end processing, and read ICDRR (dummy read). SCL is free.
5. Clear TDRE.

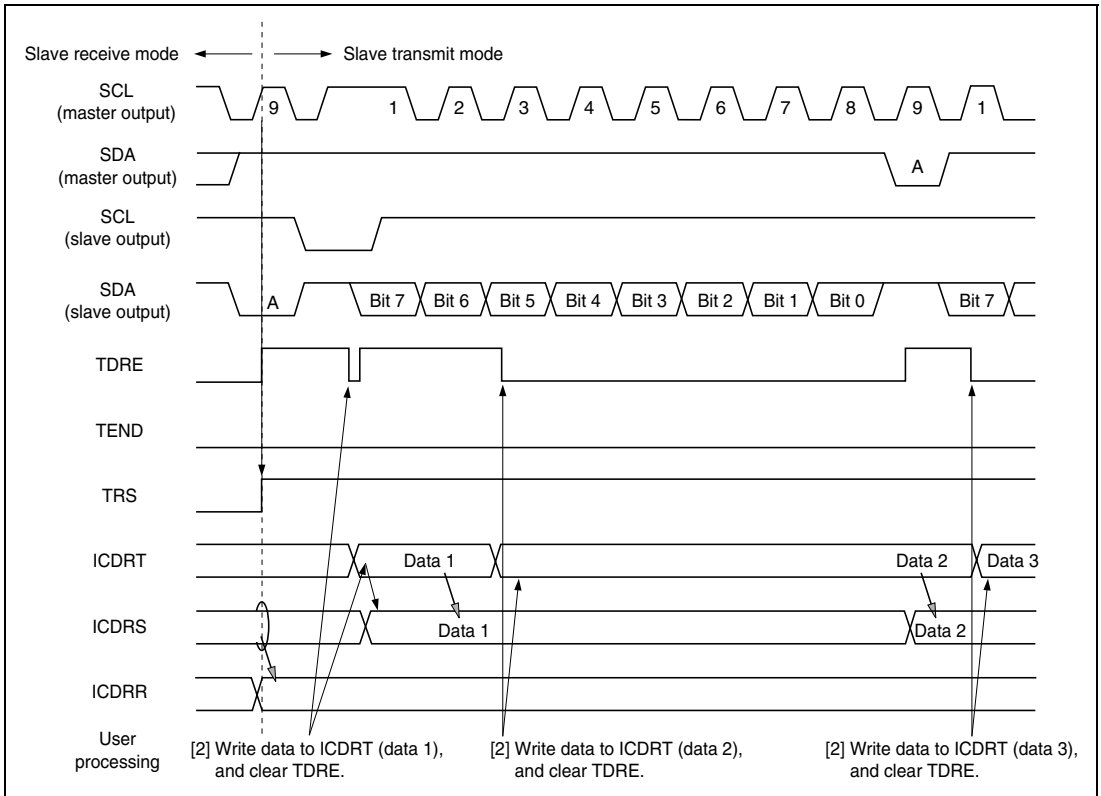

Figure 15.9 Slave Transmit Mode Operation Timing 1

before clearing RDRF, to be returned to the master device, is reflected to the next transmit frame.

4. The last byte data is read by reading ICDRR.

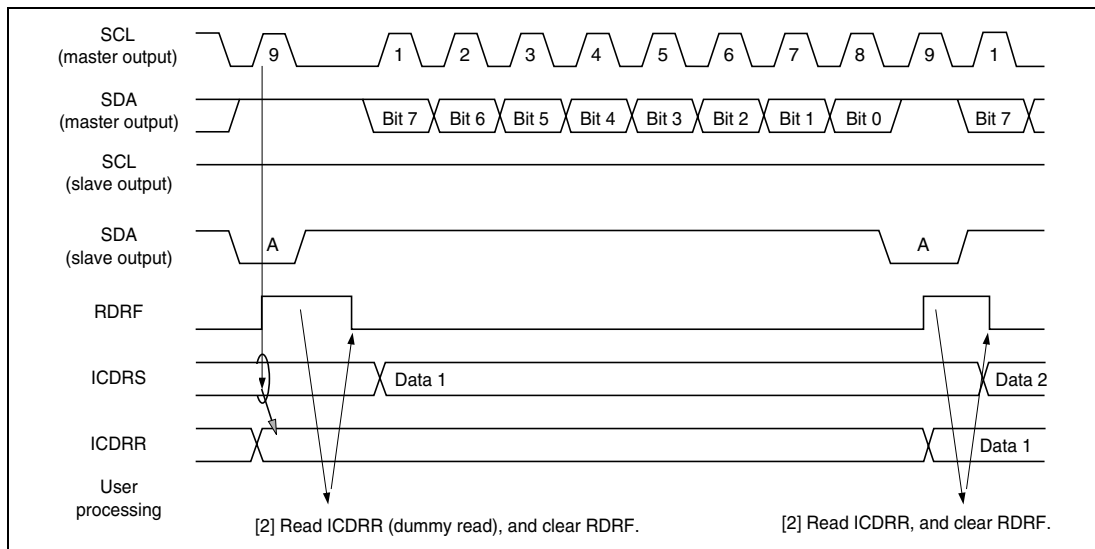

Figure 15.11 Slave Receive Mode Operation Timing 1

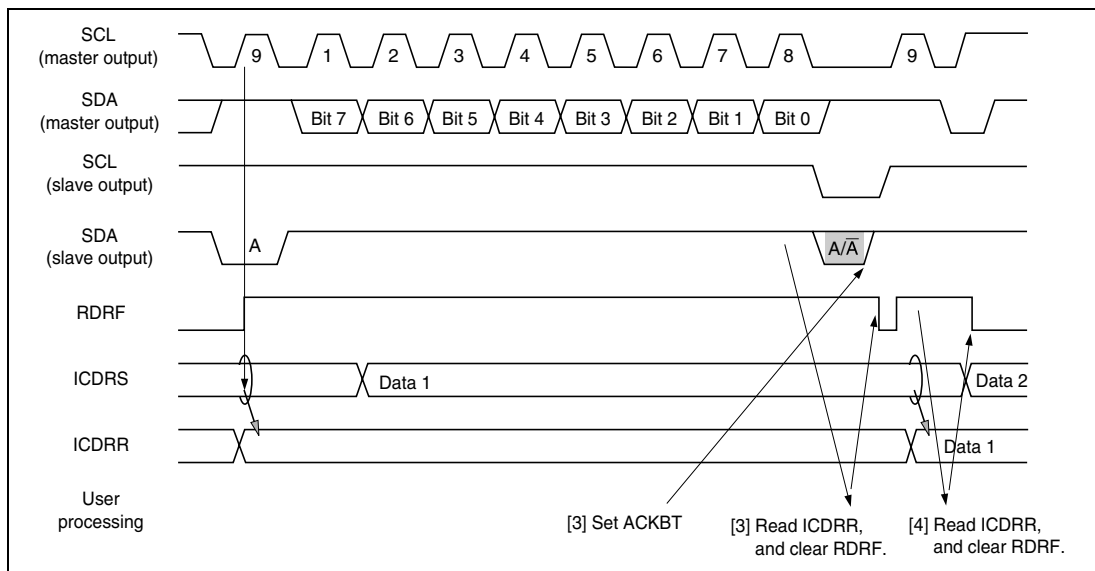

Figure 15.12 Slave Receive Mode Operation Timing 2

15.4.6 Noise Canceler

The logic levels at the SCL and SDA pins are routed through noise cancelers before being latched internally. Figure 15.13 shows a block diagram of the noise canceler circuit.

The noise canceler consists of two cascaded latches and a match detector. The SCL (or SDA) input signal is sampled on the system clock, but is not passed forward to the next circuit unless the outputs of both latches agree. If they do not agree, the previous value is held.

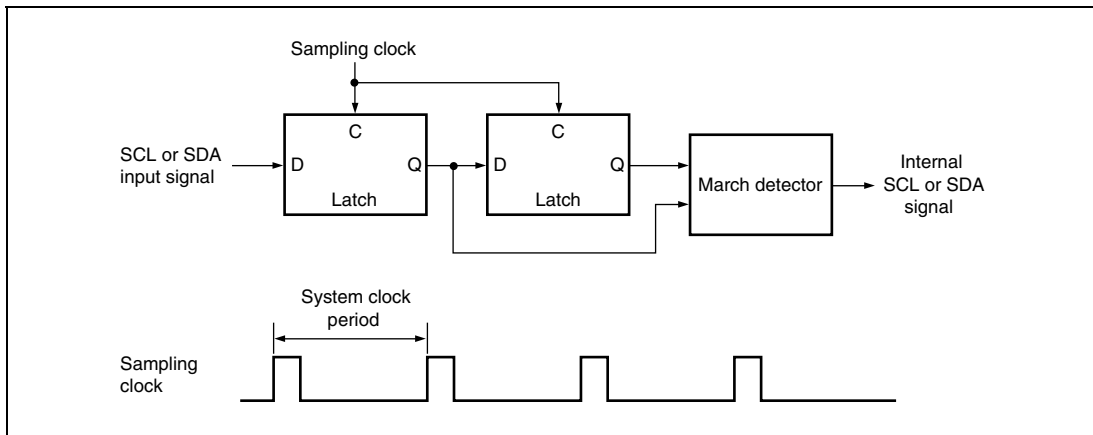

Figure 15.13 Block Diagram of Noise Canceler

15.4.7 Example of Use

Flowcharts in respective modes that use the I²C bus interface are shown in figures 15.14 to 15.17.

15.5 Interrupt Request

There are six interrupt requests in this module; transmit data empty, transmit end, receive data full, NACK receive, STOP recognition, and arbitration lost. Table 15.3 shows the contents of each interrupt request.

Table 15.3 Interrupt Requests

Interrupt Request	Abbreviation	Interrupt Condition
Transmit Data Empty	TXI	$(TDRE=1) \cdot (TIE=1)$
Transmit End	TEI	$(TEND=1) \cdot (TEIE=1)$
Receive Data Full	RXI	$(RDRF=1) \cdot (RIE=1)$
STOP Recognition	STPI	$(STOP=1) \cdot (STIE=1)$
NACK Detection	NAKI	$\{(NACKF=1)+(AL=1)\} \cdot (NAKIE=1)$
Arbitration Lost		

15.6 Bit Synchronous Circuit

In master mode,

- When SCL is driven to low by the slave device
- When the rising speed of SCL is lower by the load of the SCL line (load capacitance or pull-up resistance)

This module has a possibility that high level period may be short in the two states described above. Therefore it monitors SCL and communicates by bit with synchronization.

Figure 15.18 shows the timing of the bit synchronous circuit and table 15.4 shows the time when SCL output changes from low to Hi-Z then SCL is monitored.

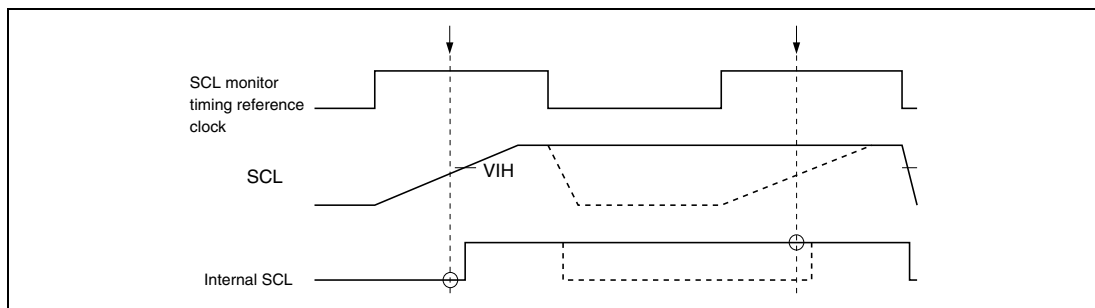

Figure 15.18 Timing of the Bit Synchronous Circuit

Table 15.4 Time for monitoring SCL

CKS3	CKS2	Time for monitoring SCL
0	0	7.5 tcyc
	1	19.5 tcyc
1	0	17.5 tcyc
	1	41.5 tcyc

Section 16 A/D Converter

This LSI includes a successive approximation type 10-bit A/D converter that allows up to ten analog input channels to be selected. The block diagram of A/D converter is shown in figure 16.1.

16.1 Features

- 10-bit resolution
- Ten input channels
- Conversion time: 8.1 μ s per channel (at 33 MHz operation)
- Two kinds of operating modes
 - Single mode: Single-channel A/D conversion
 - Scan mode: Continuous A/D conversion on 1 to 4 channels or 1 to 8 channels
- Eight data registers
 - Conversion results are held in a 16-bit data register for each channel
- Sample and hold function
- Three kinds of conversion start
 - Conversion can be started by software, 16-bit timer pulse unit (TPU), conversion start trigger by 8-bit timer (TMR), or external trigger signal.
- Interrupt request
 - A/D conversion end interrupt (ADI) request can be generated
- Module stop mode can be set

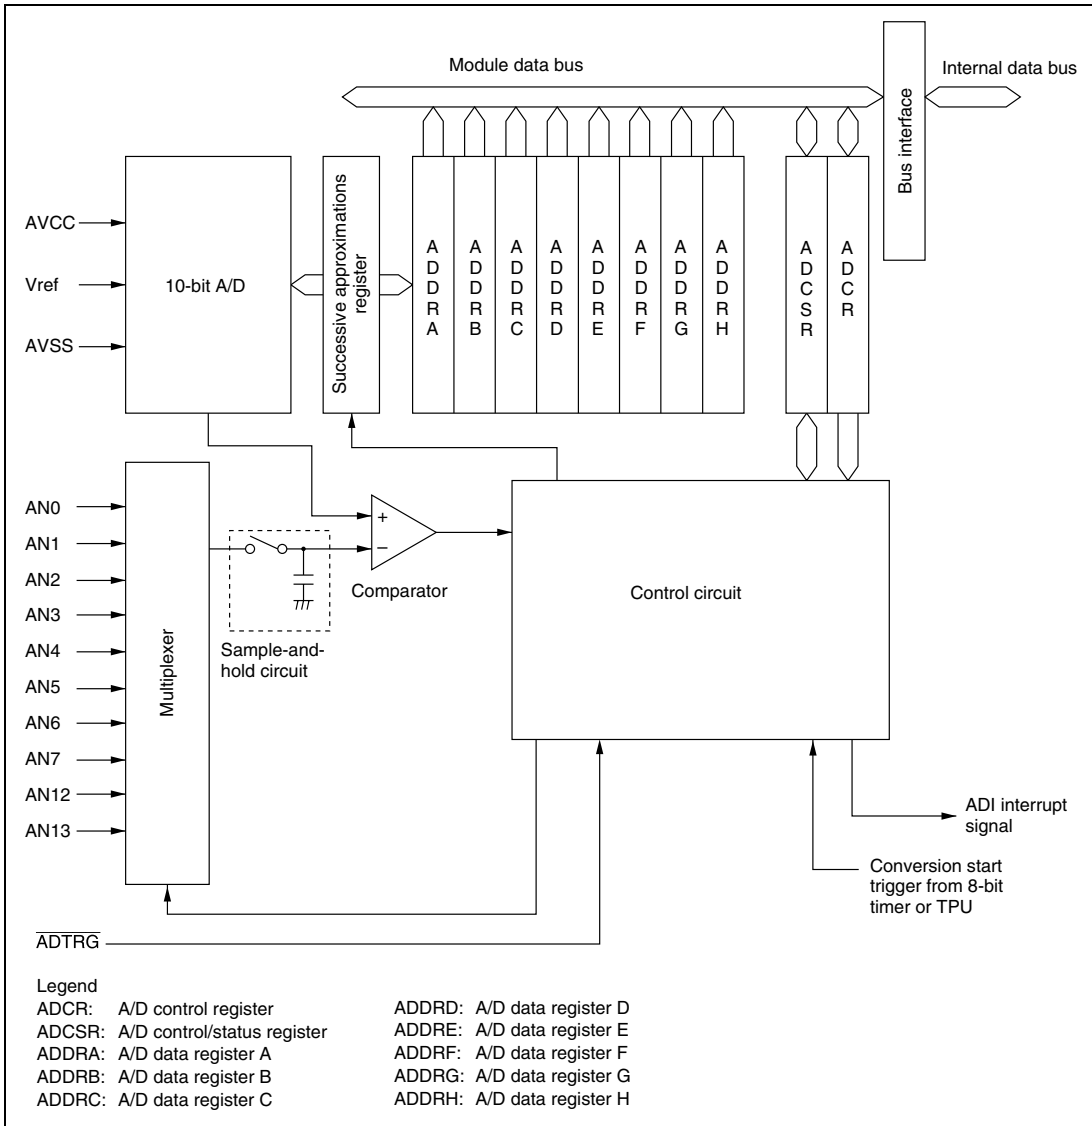

Figure 16.1 Block Diagram of A/D Converter

16.2 Input/Output Pins

Table 16.1 summarizes the input pins used by the A/D converter.

The AV_{CC} and AV_{SS} pins are the power supply pins for the analog block in the A/D converter. The V_{ref} pin is the A/D conversion reference voltage pin.

The sixteen analog input pins are divided into two channel sets: channel set 0 (AN0 to AN7) and channel set 1 (AN12 and AN13).

Table 16.1 Pin Configuration

Pin Name	Symbol	I/O	Function
Analog power supply pin	AV_{CC}	Input	Analog block power supply
Analog ground pin	AV_{SS}	Input	Analog block ground
Reference voltage pin	V_{ref}	Input	A/D conversion reference voltage
Analog input pin 0	AN0	Input	Channel set 0 analog inputs
Analog input pin 1	AN1	Input	
Analog input pin 2	AN2	Input	
Analog input pin 3	AN3	Input	
Analog input pin 4	AN4	Input	
Analog input pin 5	AN5	Input	
Analog input pin 6	AN6	Input	
Analog input pin 7	AN7	Input	
Analog input pin 12	AN12	Input	Channel set 1 analog inputs
Analog input pin 13	AN13	Input	
A/D external trigger input pin	\overline{ADTRG}	Input	External trigger input for starting A/D conversion

16.3 Register Descriptions

The A/D converter has the following registers.

- A/D data register A (ADDRA)
- A/D data register B (ADDRB)
- A/D data register C (ADDRC)
- A/D data register D (ADDRD)
- A/D data register E (ADDRE)
- A/D data register F (ADDRF)
- A/D data register G (ADDRG)
- A/D data register H (ADDRH)
- A/D control/status register (ADCSR)
- A/D control register (ADCR)

16.3.1 A/D Data Registers A to H (ADDRA to ADDRH)

There are eight 16-bit read-only ADDR registers, ADDRA to ADDRH, used to store the results of A/D conversion. The ADDR registers, which store a conversion result for each channel, are shown in table 16.2.

The converted 10-bit data is stored to bits 15 to 6. The lower 6-bit data is always read as 0.

The data bus between the CPU and the A/D converter is 16-bit width. The data can be read directly from the CPU.

Table 16.2 Analog Input Channels and Corresponding ADDR Registers

Analog Input Channel		A/D Data Register which Stores Conversion Result
Channel Set 0 (CH3 = 0)	Channel Set 1 (CH3 = 1)	
AN0	—	ADDRA
AN1	—	ADDRB
AN2	—	ADDRC
AN3	—	ADDRD
AN4	AN12	ADDRE
AN5	AN13	ADDRF
AN6	—	ADDRG
AN7	—	ADDRH

16.3.2 A/D Control/Status Register (ADCSR)

ADCSR controls A/D conversion operations.

Bit	Bit Name	Initial Value	R/W	Description
7	ADF	0	R/(W)*	<p>A/D End Flag</p> <p>A status flag that indicates the end of A/D conversion.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none">• When A/D conversion ends in single mode• When A/D conversion ends on all specified channels in scan mode <p>[Clearing conditions]</p> <ul style="list-style-type: none">• When 0 is written after reading ADF = 1• When the DTC or DMAC is activated by an ADI interrupt and ADDR is read
6	ADIE	0	R/W	<p>A/D Interrupt Enable</p> <p>A/D conversion end interrupt (ADI) request enabled when 1 is set</p>
5	ADST	0	R/W	<p>A/D Start</p> <p>Clearing this bit to 0 stops A/D conversion, and the A/D converter enters wait state. When this bit is set to 1 by software, TPU (trigger), TMR (trigger), or the $\overline{\text{ADTRG}}$ pin, A/D conversion starts. This bit remains set to 1 during A/D conversion. In single mode, cleared to 0 automatically when conversion on the specified channel ends. In scan mode, conversion continues sequentially on the specified channels until this bit is cleared to 0 by a reset, or a transition to hardware standby mode or software standby mode.</p>
4	—	0	—	<p>Reserved</p> <p>This bit is always read as 0 and cannot be modified.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	CH3	0	R/W	Channel select 3 to 0
2	CH2	0	R/W	Selects analog input together with bits SCANE and SCANS in ADCR.
1	CH1	0	R/W	
0	CH0	0	R/W	Set the input channel when conversion is stopped (ADST = 0). When SCANE = 0 and SCANS = X 0000: AN0 10xx: Cannot be set 0001: AN1 10xx: Cannot be set 0010: AN2 10xx: Cannot be set 0011: AN3 10xx: Cannot be set 0100: AN4 1100: AN12 0101: AN5 1101: AN13 0110: AN6 111x: Cannot be set 0111: AN7 111x: Cannot be set When SCANE = 1 and SCANS = 0 0000: AN0 1000: AN8 0001: AN0 and AN1 1001: AN8 and AN9 0010: AN0 to AN2 1010: AN8 to AN10 0011: AN0 to AN3 1011: AN8 to AN11 0100: AN4 1100: AN12 0101: AN4 and AN5 1101: AN12 and AN13 0110: AN4 to AN6 1110: AN12 to AN14 0111: AN4 to AN7 1111: AN12 to AN15 When SCANE = 1 and SCANS = 1 0000: AN0 1xxx: Cannot be set 0001: AN0 and AN1 1xxx: Cannot be set 0010: AN0 to AN2 1xxx: Cannot be set 0011: AN0 to AN3 1xxx: Cannot be set 0100: AN0 to AN4 1xxx: Cannot be set 0101: AN0 to AN5 1xxx: Cannot be set 0110: AN0 to AN6 1xxx: Cannot be set 0111: AN0 to AN7 1xxx: Cannot be set

Note: * Only 0 can be written in bit 7, to clear the flag.

Legend: X: Don't care.

16.3.3 A/D Control Register (ADCR)

ADCR enables A/D conversion start by an external trigger input.

It also sets the A/D converter operating mode and the A/D conversion time.

Bit	Bit Name	Initial Value	R/W	Description
7	TRGS1	0	R/W	Timer Trigger Select 1 and 0
6	TRGS0	0	R/W	These bits select enabling or disabling of the start of A/D conversion by a trigger signal. 00: A/D conversion start by external trigger is disabled 01: A/D conversion start by external trigger (TPU) is enabled 10: A/D conversion start by external trigger (TMR) is enabled 11: A/D conversion start by external trigger pin (ADTRG) is enabled
5	SCANE	0	R/W	Scan Mode
4	SCANS	0	R/W	Selects single mode or scan mode as the A/D conversion operating mode. 0x: Single mode 10: Scan mode. A/D conversion is performed continuously for channels 1 to 4 11: Scan mode. A/D conversion is performed continuously for channels 1 to 8.
3	CKS1	0	R/W	Clock Select 1 to 0
2	CKS0	0	R/W	Sets the A/D conversion time. Only set bits CKS1 and CKS0 while conversion is stopped (ADST = 0). 00: A/D conversion time = 530 states (max) 01: A/D conversion time = 266 states (max) 10: A/D conversion time = 134 states (max) 11: A/D conversion time = 68 states (max)
1	—	0	—	Reserved
0	—	0	—	These bits are always read as 0 and cannot be modified.

Legend: X: Don't care.

16.4 Operation

The A/D converter operates by successive approximation with 10-bit resolution. It has two operating modes: single mode and scan mode. When changing the operating mode or analog input channel, to prevent incorrect operation, first clear the bit ADST to 0 in ADCSR to halt A/D conversion. The ADST bit can be set at the same time as the operating mode or analog input channel is changed.

16.4.1 Single Mode

In single mode, A/D conversion is to be performed only once on the specified single channel. Operations are as follows.

1. A/D conversion is started when the ADST bit in ADCSR is set to 1, according to the software or external trigger input.
2. When A/D conversion is completed, the result is transferred to the corresponding A/D data register to the channel.
3. On completion of conversion, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
4. The ADST bit remains set to 1 during A/D conversion, and is automatically cleared to 0 when conversion ends. When the ADST bit is cleared to 0 during A/D conversion, A/D conversion stops and the A/D converter enters wait state.

16.4.2 Scan Mode

In scan mode, A/D conversion is to be performed sequentially on the specified channels: maximum four channels or maximum eight channels. Operations are as follows.

1. When the ADST bit in ADCSR is set to 1 by software, TPU or external trigger input, A/D conversion starts on the first channel in the group.
The consecutive A/D conversion on maximum four channels (SCANE and SCANS = 10) or on maximum eight channels (SCANE and SCANS = 11) can be selected. When the consecutive A/D conversion is performed on the four channels, the A/D conversion starts on AN0 when CH3 = 1 and CH2 = 1, AN4 when CH3 and CH2 = 01, or AN12 when CH3 and CH2 = 11. When the consecutive A/D conversion is performed on the eight channels, the A/D conversion starts on AN0 when CH3 = 0.
2. When A/D conversion for each channel is completed, the result is sequentially transferred to the corresponding A/D data register to each channel.
3. When conversion of all the selected channels is completed, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt is requested. Conversion of the first channel in the group starts again.

4. The ADST bit is not cleared automatically, and steps [2] and [3] are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops and the A/D converter enters wait state. If the ADST bit is later set to 1, A/D conversion starts again from the first channel in the group.

16.4.3 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input when A/D conversion start delay time (t_D) passes after the ADST bit is set to 1, then starts conversion. Figure 16.2 shows the A/D conversion timing. Table 16.3 indicates the A/D conversion time.

As indicated in figure 16.2, the A/D conversion time (t_{CONV}) includes t_D and the input sampling time (t_{SPL}). The length of t_D varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in tables 16.3.

In scan mode, the values given in table 16.3 apply to the first conversion time. The values given in table 16.4 apply to the second and subsequent conversions.

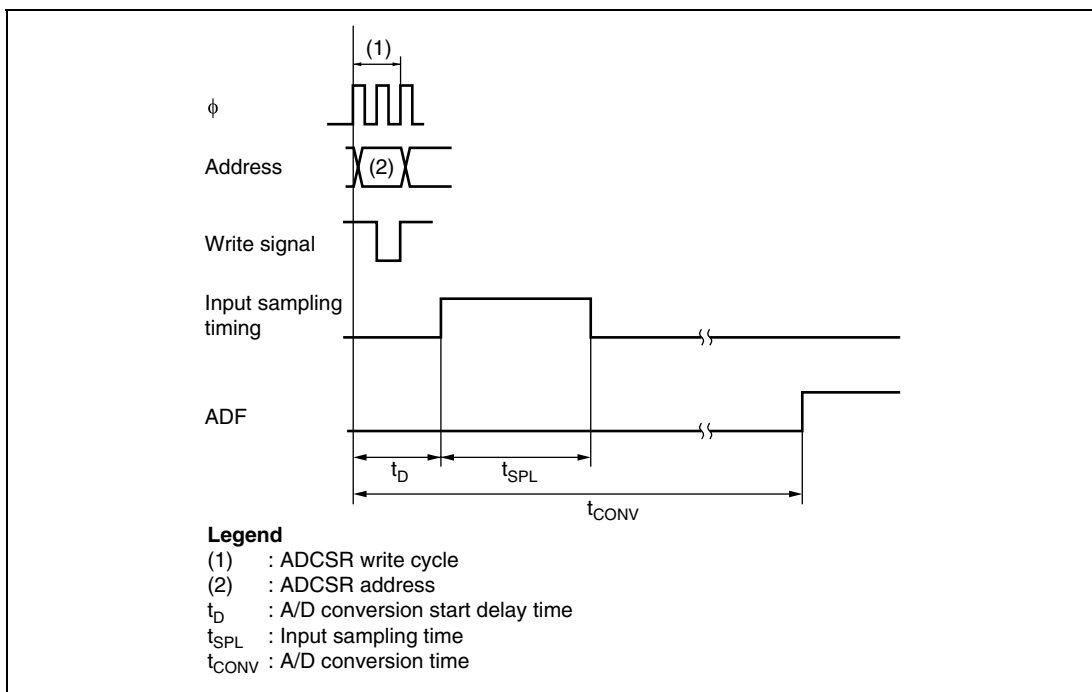

Figure 16.2 A/D Conversion Timing

Table 16.3 A/D Conversion Time (Single Mode)

Item	Symbol	CKS1 = 0						CKS1 = 1					
		CKS0 = 0			CKS0 = 1			CKS0 = 0			CKS0 = 1		
		Min	Typ	Max	Min	Typ	Max	Min	Typ	Max	Min	Typ	Max
A/D conversion start delay time	t_D	18	—	33	10	—	16	6	—	9	4	—	5
Input sampling time	t_{SPL}	—	127	—	—	63	—	—	31	—	—	15	—
A/D conversion time	t_{CONV}	515	—	530	259	—	266	131	—	134	67	—	68

Note: Values in the table are the number of states.

Table 16.4 A/D Conversion Time (Scan Mode)

CKS1	CKS0	Conversion Time (State)
0	0	512 (Fixed)
	1	256 (Fixed)
1	0	128 (Fixed)
	1	64 (Fixed)

16.4.4 External Trigger Input Timing

A/D conversion can be externally triggered. When the TRGS1 and TRGS0 bits are set to 11 in ADCR, external trigger input is enabled at the $\overline{\text{ADTRG}}$ pin. A falling edge at the $\overline{\text{ADTRG}}$ pin sets the ADST bit to 1 in ADCSR, starting A/D conversion. Other operations, in both single and scan modes, are the same as when the bit ADST has been set to 1 by software. Figure 16.3 shows the timing.

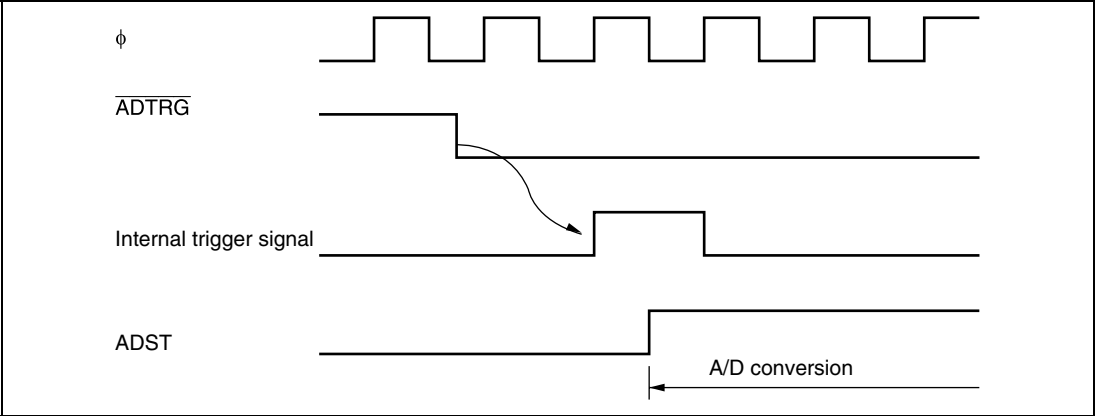

Figure 16.3 External Trigger Input Timing

16.5 Interrupts

The A/D converter generates an A/D conversion end interrupt (ADI) at the end of A/D conversion. Setting the ADIE bit to 1 enables an ADI interrupt requests while the bit ADF in ADCSR is set to 1 after A/D conversion is completed. The DTC or DMAC* can be activated by an ADI interrupt. Having the converted data read by the DTC or DMAC* in response to an ADI interrupt enables continuous conversion to be achieved without imposing a load on software.

Note: * Not supported by the H8S/2366.

Table 16.5 A/D Converter Interrupt Source

Name	Interrupt Source	Interrupt Flag	DTC Activation	DMAC* Activation
ADI	End of conversion	ADF	Possible	Possible

Note: * Not supported by the H8S/2366.

16.6 A/D Conversion Precision Definitions

This LSI's A/D conversion precision definitions are given below.

- Resolution
The number of A/D converter digital output codes
- Quantization error
The deviation inherent in the A/D converter, given by 1/2 LSB (see figure 16.4).
- Offset error
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from the minimum voltage value B'0000000000 (H'000) to B'0000000001 (H'001) (see figure 16.5).
- Full-scale error
The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from B'1111111110 (H'3FE) to B'1111111111 (H'3FF) (see figure 16.5).
- Nonlinearity error
The error with respect to the ideal A/D conversion characteristic between the zero voltage and the full-scale voltage. Does not include the offset error, full-scale error, or quantization error (see figure 16.5).
- Absolute precision
The deviation between the digital value and the analog input value. Includes the offset error, full-scale error, quantization error, and nonlinearity error.

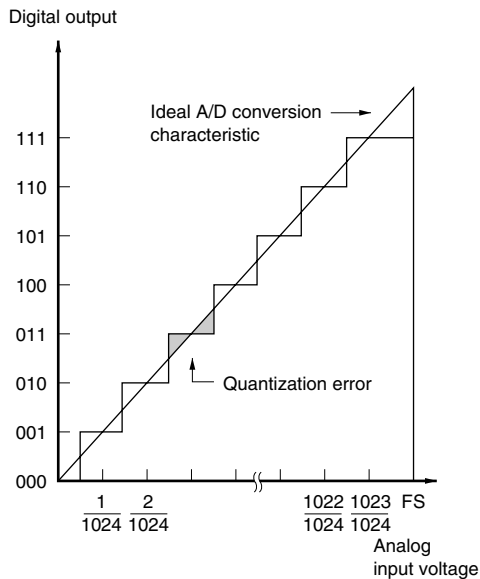

Figure 16.4 A/D Conversion Precision Definitions

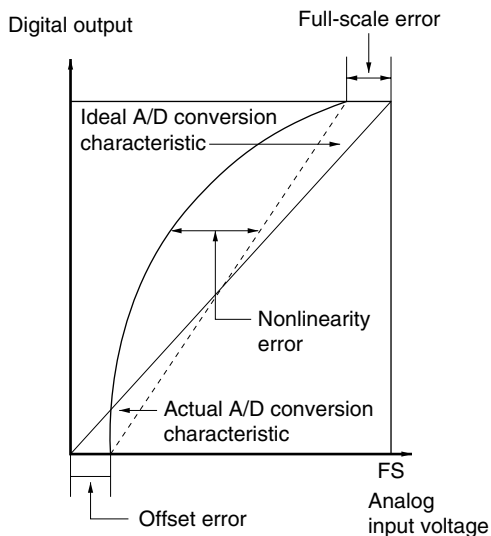

Figure 16.5 A/D Conversion Precision Definitions

16.7 Usage Notes

16.7.1 Module Stop Mode Setting

Operation of the A/D converter can be disabled or enabled using the module stop control register. The initial setting is for operation of the A/D converter to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 22, Power-Down Modes.

16.7.2 Permissible Signal Source Impedance

This LSI's analog input is designed so that conversion precision is guaranteed for an input signal for which the signal source impedance is $5\text{ k}\Omega$ or less. This specification is provided to enable the A/D converter's sample-and-hold circuit input capacitance to be charged within the sampling time; if the sensor output impedance exceeds $5\text{ k}\Omega$, charging may be insufficient and it may not be possible to guarantee the A/D conversion precision. However, if a large capacitance is provided externally for conversion in single mode, the input load will essentially comprise only the internal input resistance of $10\text{ k}\Omega$, and the signal source impedance is ignored. However, since a low-pass filter effect is obtained in this case, it may not be possible to follow an analog signal with a large differential coefficient (e.g., $5\text{ mV}/\mu\text{s}$ or greater) (see figure 16.6). When converting a high-speed analog signal or conversion in scan mode, a low-impedance buffer should be inserted.

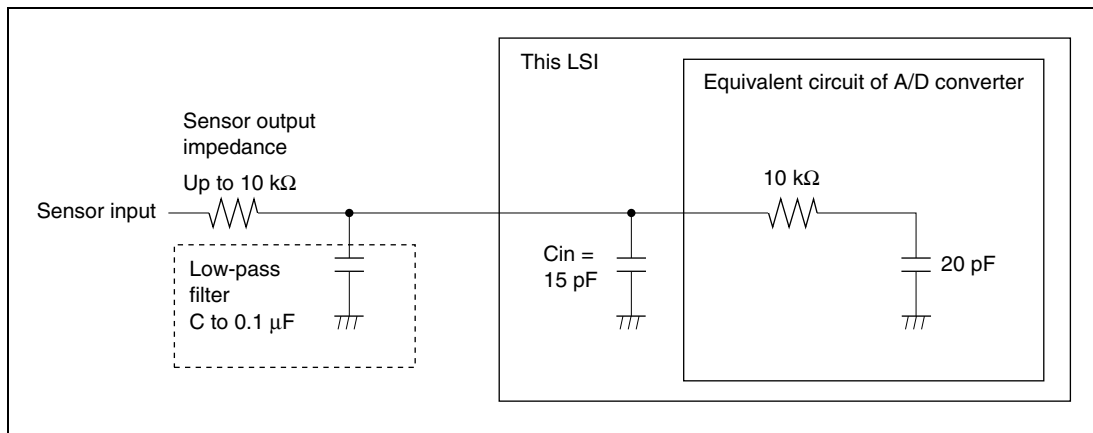

Figure 16.6 Example of Analog Input Circuit

16.7.3 Influences on Absolute Precision

Adding capacitance results in coupling with GND, and therefore noise in GND may adversely affect absolute precision. Be sure to make the connection to an electrically stable GND such as AVss.

Care is also required to insure that filter circuits do not communicate with digital signals on the mounting board, so acting as antennas.

16.7.4 Setting Range of Analog Power Supply and Other Pins

If conditions shown below are not met, the reliability of the device may be adversely affected.

- Analog input voltage range

The voltage applied to analog input pin ANn during A/D conversion should be in the range $AV_{ss} \leq AV_n \leq V_{ref}$.

- Relation between AVcc, AVss and Vcc, Vss

As the relationship between AVcc, AVss and Vcc, Vss, set $AV_{cc} \geq V_{cc}$ and $AV_{ss} = V_{ss}$. If the A/D converter is not used, the AVcc and AVss pins must not be left open.

- Vref setting range

The reference voltage at the Vref pin should be set in the range $V_{ref} \leq AV_{cc}$.

16.7.5 Notes on Board Design

In board design, digital circuitry and analog circuitry should be as mutually isolated as possible, and layout in which digital circuit signal lines and analog circuit signal lines cross or are in close proximity should be avoided as far as possible. Failure to do so may result in incorrect operation of the analog circuitry due to inductance, adversely affecting A/D conversion values.

Also, digital circuitry must be isolated from the analog input signals (AN0 to AN7, AN12, AN13), analog reference power supply (Vref), and analog power supply (AVcc) by the analog ground (AVss). Also, the analog ground (AVss) should be connected at one point to a stable digital ground (Vss) on the board.

16.7.6 Notes on Noise Countermeasures

A protection circuit connected to prevent damage due to an abnormal voltage such as an excessive surge at the analog input pins (AN0 to AN7, AN12, AN13) should be connected between AVcc and AVss as shown in figure 16.7. Also, the bypass capacitors connected to AVcc and the filter capacitor connected to AN0 to AN15 must be connected to AVss.

If a filter capacitor is connected, the input currents at the analog input pins (AN0 to AN7, AN12, AN13) are averaged, and so an error may arise. Also, when A/D conversion is performed frequently, as in scan mode, if the current charged and discharged by the capacitance of the sample-and-hold circuit in the A/D converter exceeds the current input via the input impedance (R_{in}), an error will arise in the analog input pin voltage. Careful consideration is therefore required when deciding the circuit constants.

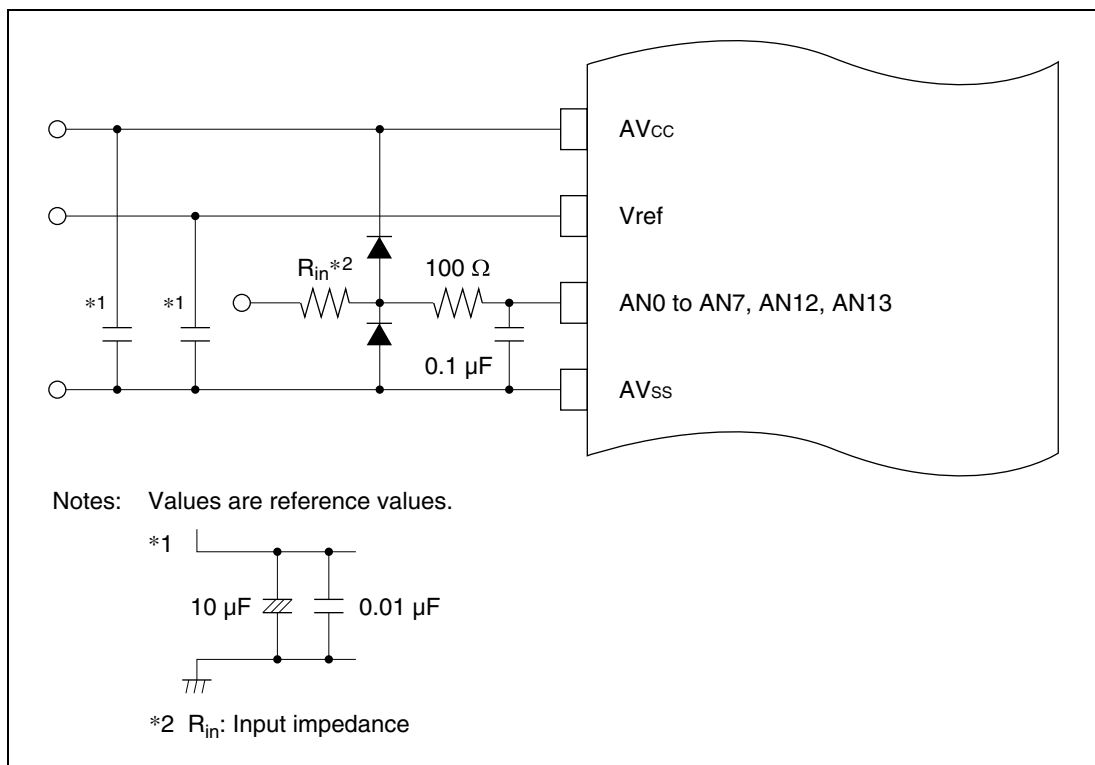

Figure 16.7 Example of Analog Input Protection Circuit

Table 16.6 Analog Pin Specifications

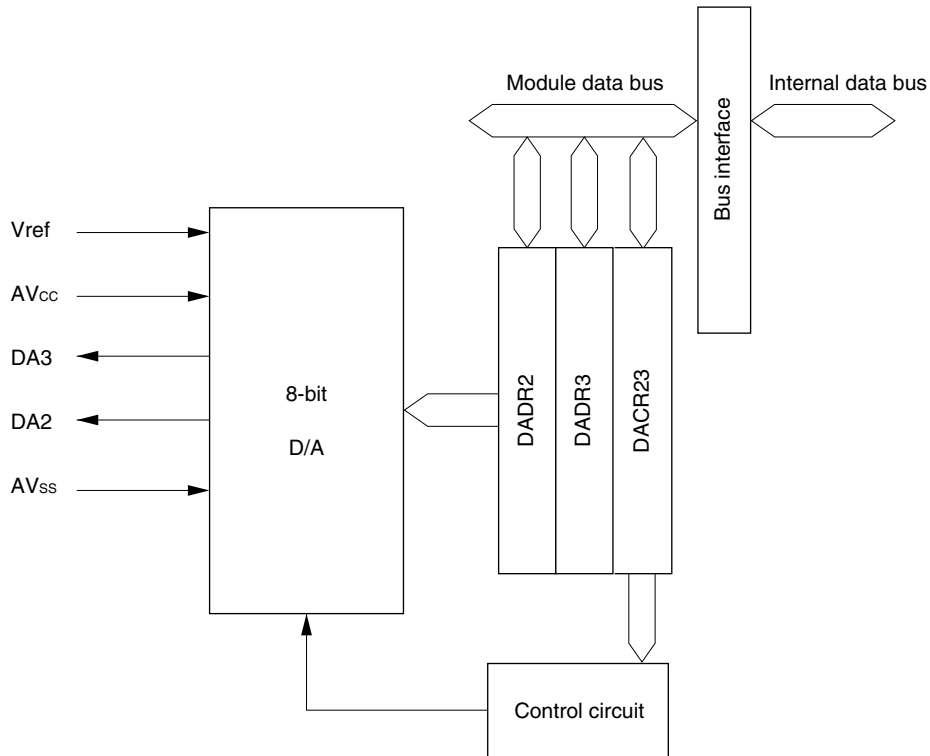

Item	Min	Max	Unit
Analog input capacitance	—	20	pF
Permissible signal source impedance	—	5	k Ω

Section 17 D/A Converter

17.1 Features

D/A converter features are listed below.

- 8-bit resolution
- Two output channels
- Maximum conversion time of 10 μ s (with 20 pF load)
- Output voltage of 0 V to Vref
- D/A output hold function in software standby mode
- Setting the module stop mode

Legend

DADR2: D/A data register 2
DADR3: D/A data register 3
DADR4: D/A data register 4
DACR23: D/A control register 23

Figure 17.1 Block Diagram of D/A Converter

17.2 Input/Output Pins

Table 17.1 summarizes the input and output pins of the D/A converter.

Table 17.1 Pin Configuration

Pin Name	Symbol	I/O	Function
Analog power pin	AV _{CC}	Input	Analog power
Analog ground pin	AV _{SS}	Input	Analog ground
Reference voltage pin	V _{ref}	Input	Reference voltage of D/A converter
Analog output pin 2	DA2	Output	Channel 2 analog output
Analog output pin 3	DA3	Output	Channel 3 analog output

17.3 Register Descriptions

The D/A converter has the following registers.

- D/A data register 2 (DADR2)
- D/A data register 3 (DADR3)
- D/A control register 01 (DACR01)
- D/A control register 23 (DACR23)

17.3.1 D/A Data Registers 2 and 3 (DADR2 and DADR3)

DADR2 and DADR3 are 8-bit readable/writable registers that store data for conversion.

Whenever output is enabled, the values in DADR are converted and output to the analog output pins.

17.3.2 D/A Control Register 23 (DACR23)

DACR23 control the operation of the D/A converter.

Bit	Bit Name	Initial Value	R/W	Description
7	DAOE3	0	R/W	D/A Output Enable 3 Controls D/A conversion and analog output. 0: Analog output (DA3) is disabled 1: Channel 3 D/A conversion is enabled; analog output (DA3) is enabled
6	DAOE2	0	R/W	D/A Output Enable 2 Controls D/A conversion and analog output. 0: Analog output (DA2) is disabled 1: Channel 2 D/A conversion is enabled; analog output (DA2) is enabled
5	DAE	0	R/W	D/A Enable Used together with the DAOE0 and DAOE1 bits to control D/A conversion. When the DAE bit is cleared to 0, channel 2 and 3 D/A conversions are controlled independently. When the DAE bit is set to 1, channel 2 and 3 D/A conversions are controlled together. Output of conversion results is always controlled independently by the DAOE0 and DAOE1 bits. For details, see table 17.2.
4 to 0	—	1	—	Reserved These bits are always read as 1 and cannot be modified.

Table 17.2 Control of D/A Conversion

Bit 5 DAE	Bit 7 DAOE3	Bit 6 DAOE2	Description
0	0	0	D/A conversion disabled
		1	Channel 2 D/A conversion enabled, channel3 D/A conversion disabled
	1	0	Channel 3 D/A conversion enabled, channel2 D/A conversion disabled
		1	Channel 2 and 3 D/A conversions enabled
1	0	0	D/A conversion disabled
		1	Channel 2 and 3 D/A conversions enabled
	1	0	
		1	

17.4 Operation

The D/A converter includes D/A conversion circuits for two channels, each of which can operate independently.

When DAOE0 bit in DACR23 is set to 1, D/A conversion is enabled and the conversion result is output.

The operation example concerns D/A conversion on channel 2. Figure 17.2 shows the timing of this operation.

- [1] Write the conversion data to DADR2.
- [2] Set the DAOE0 bit in DACR23 to 1. D/A conversion is started. The conversion result is output from the analog output pin DA2 after the conversion time t_{DCONV} has elapsed. The conversion result is continued to output until DADR0 is written to again or the DAOE0 bit is cleared to 0. The output value is expressed by the following formula:

$$\frac{\text{DADRcontents}}{256} \times V_{\text{ref}}$$

- [3] If DADR2 is written to again, the conversion is immediately started. The conversion result is output after the conversion time t_{DCONV} has elapsed.
- [4] If the DAOE0 bit is cleared to 0, analog output is disabled.

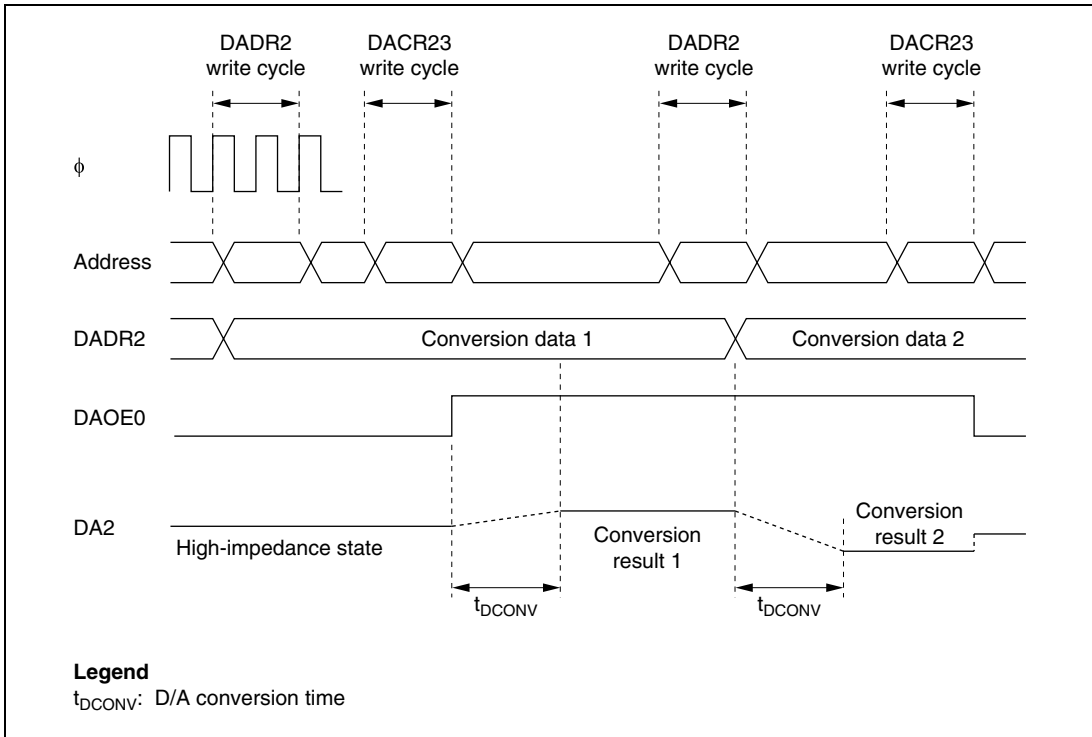

Figure 17.2 Example of D/A Converter Operation

17.5 Usage Notes

17.5.1 Setting for Module Stop Mode

It is possible to enable/disable the D/A converter operation using the module stop control register, the D/A converter does not operate by the initial value of the register. The register can be accessed by releasing the module stop mode. For details, see section 22, Power-Down Modes.

17.5.2 D/A Output Hold Function in Software Standby Mode

If D/A conversion is enabled and this LSI enters software standby mode, D/A output is held and analog power supply current remains at the same level during D/A conversion. When the analog power supply current is required to go low in software standby mode, bits DAOE2, DAOE3 and DAE should be cleared to 0, and D/A output should be disabled.

Section 18 RAM

This LSI has an on-chip high-speed static RAM. The RAM is connected to the CPU by a 16-bit data bus, enabling one-state access by the CPU to both byte data and word data.

The on-chip RAM can be enabled or disabled by means of the RAME bit in the system control register (SYSCR). For details on the system control register (SYSCR), refer to section 3.2.2, System Control Register (SYSCR).

- Size

Product Classification		ROM Size	ROM Address
H8S/2368 Group	HD64F2367	384 kbytes	H'000000 to H'05FFFF (Modes 3, 4, and 7)
	HD64F2366		

- Programming/erase methods

The flash memory is programmed 128 bytes at a time. Erase is performed in single-block units. The flash memory of 384 kbytes is configured as follows: 64 kbytes \times 5 blocks, 32 kbytes \times 1 block, and 4 kbytes \times 8 blocks. To erase the entire flash memory, each block must be erased in turn.

- Reprogramming capability

The flash memory can be reprogrammed up to 100 times.

- Two on-board programming modes

Boot mode

User program mode

On-board programming/erasing can be done in boot mode in which the on-chip boot program is started for erase or programming of the entire flash memory. In normal user program mode, individual blocks can be erased or programmed.

- Programmer mode

Flash memory can be programmed/erased in programmer mode, using a PROM programmer, as well as in on-board programming mode.

- Automatic bit rate adjustment

With data transfer in boot mode, the bit rate of this LSI can be automatically adjusted to match the transfer bit rate of the host.

- Flash memory emulation by RAM*

Part of the RAM area can be overlapped onto flash memory, to emulate flash memory updates in real time.

Note: * This function is not supported by the H8S/2367 or H8S/2366.

- Programming/erasing protection

There are three protect modes, hardware, software, and error protect, which allow protected status to be designated for flash memory program/erase operations.

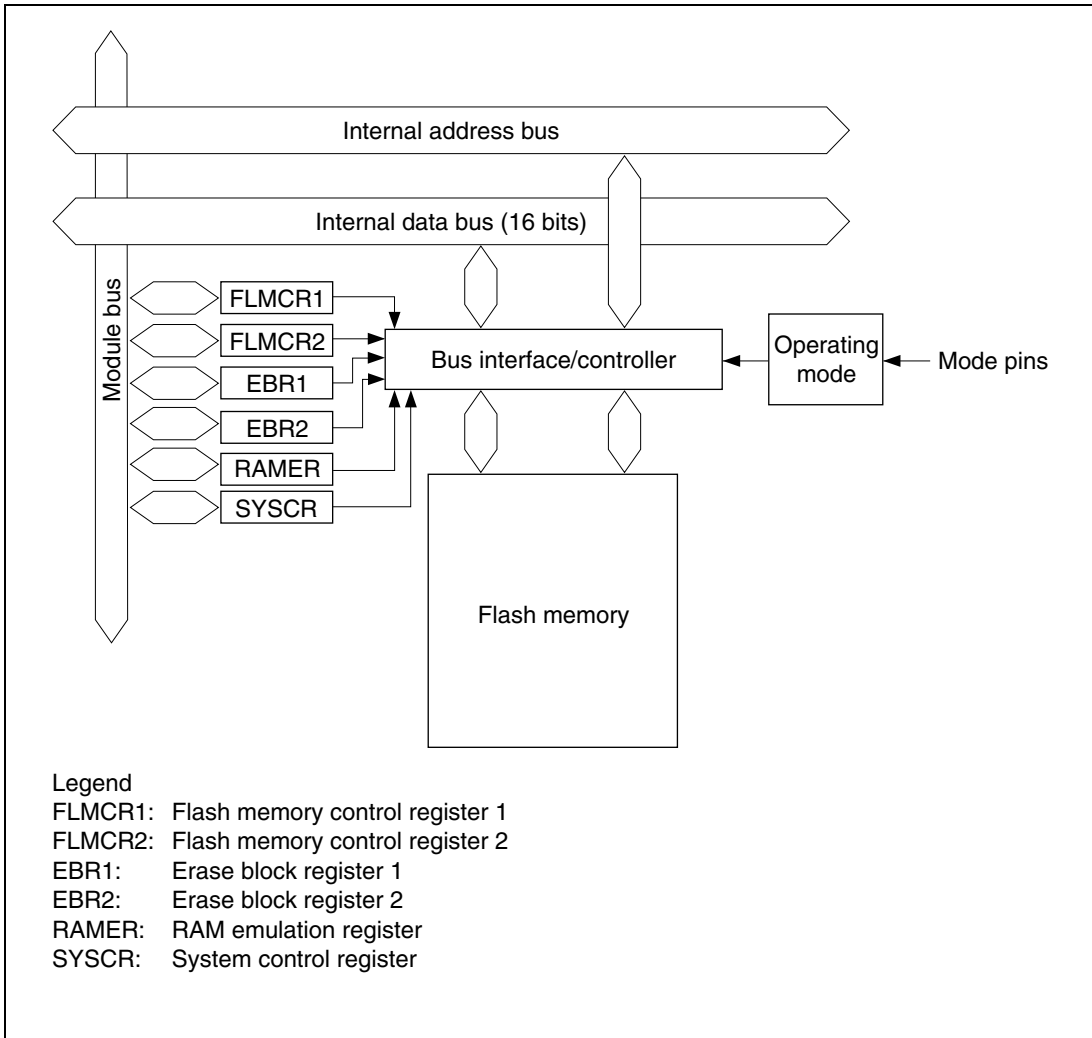

Figure 19.1 Block Diagram of Flash Memory

19.2 Mode Transitions

When the mode pins are set in the reset state and a reset-start is executed, this LSI enters an operating mode as shown in figure 19.2. In user mode, flash memory can be read but not programmed or erased.

The boot, user program and programmer modes are provided as modes to write and erase the flash memory.

The differences between boot mode and user program mode are shown in table 19.1. Figure 19.3 shows boot mode. Figure 19.4 shows user program mode.

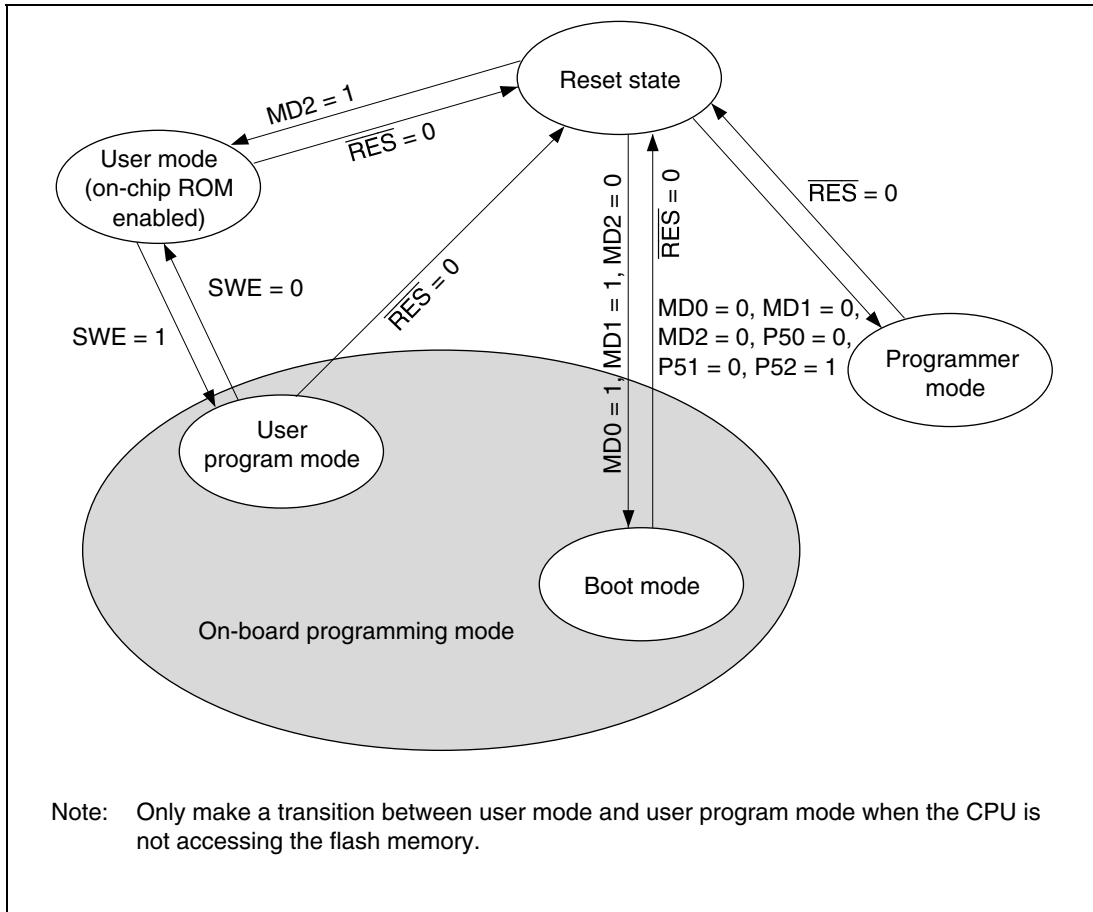

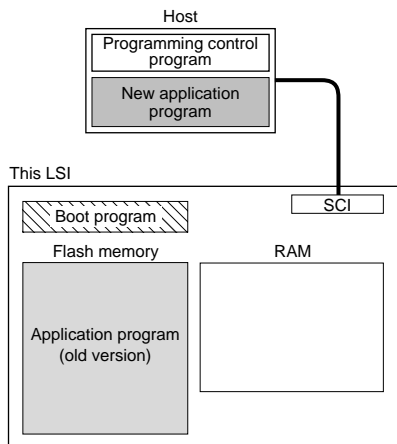

Figure 19.2 Flash Memory State Transitions

Table 19.1 Differences between Boot Mode and User Program Mode

	Boot Mode	User Program Mode
Total erase	Yes	Yes
Block erase	No	Yes
Programming control program*	Program/program-verify	Erase/erase-verify/program/ program-verify emulation

Note: * To be provided by the user, in accordance with the recommended algorithm.

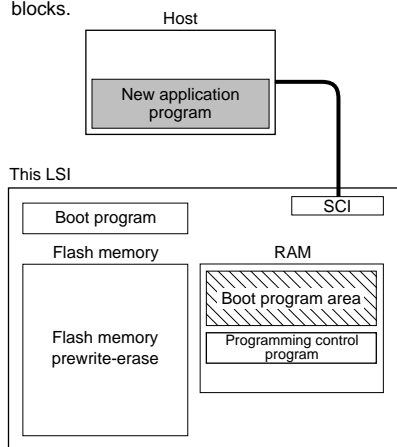

1. Initial state
The old program version or data remains written in the flash memory. The user should prepare the programming control program and new application program beforehand in the host.

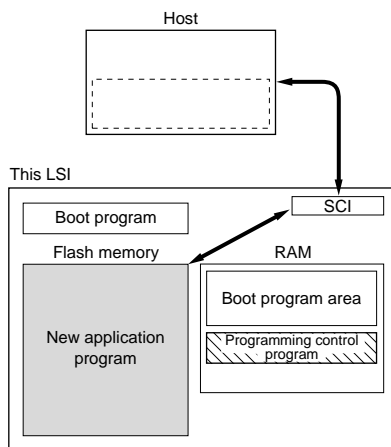

2. Programming control program transfer
When boot mode is entered, the boot program in the chip (originally incorporated in the chip) is started and the programming control program in the host is transferred to RAM via SCI communication. The boot program required for flash memory erasing is automatically transferred to the RAM boot program area.

3. Flash memory initialization
The erase program in the boot program area (in RAM) is executed, and the flash memory is initialized (to H'FF). In boot mode, entire flash memory erasure is performed, without regard to blocks.

4. Writing new application program
The programming control program transferred from the host to RAM is executed, and the new application program in the host is written into the flash memory.

 Program execution state

Figure 19.3 Boot Mode

1. Initial state
(1) the program that will transfer the programming/ erase control program to on-chip RAM should be written into the flash memory by the user beforehand. (2) The programming/erase control program should be prepared in the host or in the flash memory.
2. Programming/erase control program transfer
When user program mode is entered, user software confirms this fact, executes the transfer program in the flash memory, and transfers the programming/erase control program to RAM.

3. Flash memory initialization
The programming/erase program in RAM is executed, and the flash memory is initialized (to H'FF). Erasing can be performed in block units, but not in byte units.
4. Writing new application program
Next, the new application program in the host is written into the erased flash memory blocks. Do not write to unerased blocks.

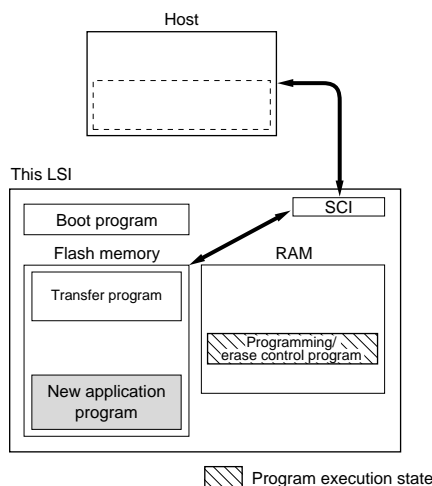

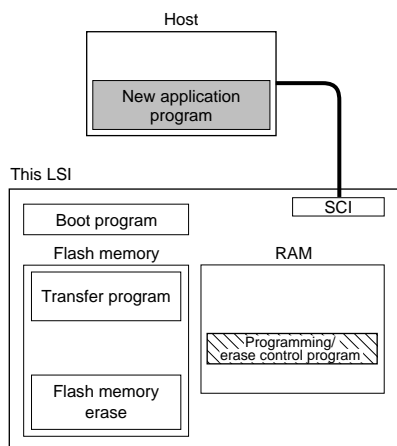

Figure 19.4 User Program Mode

19.3 Block Configuration

Figure 19.5 shows the block configuration of 384-kbyte flash memory. The thick lines indicate erasing units, the narrow lines indicate programming units, and the values are addresses. The 384-kbyte flash memory is divided into 64 kbytes (5 blocks), 32 kbytes (1 block), and 4 kbytes (8 blocks). Erasing is performed in these divided units. Programming is performed in 128-byte units starting from an address whose lower eight bits are H'00 or H'80.

EB0 Erase unit 4 kbytes	H'000000	H'000001	H'000002	← Programming unit: 128 bytes →	H'00007F
				-----	H'000FFF
EB1 Erase unit 4 kbytes	H'001000	H'001001	H'001002	← Programming unit: 128 bytes →	H'00107F
				-----	H'001FFF
EB2 Erase unit 4 kbytes	H'002000	H'002001	H'002002	← Programming unit: 128 bytes →	H'00207F
				-----	H'002FFF
EB3 Erase unit 4 kbytes	H'003000	H'003001	H'003002	← Programming unit: 128 bytes →	H'00307F
				-----	H'003FFF
EB4 Erase unit 4 kbytes	H'004000	H'004001	H'004002	← Programming unit: 128 bytes →	H'00407F

EB7 Erase unit 4 kbytes	H'007000	H'007001	H'007002	← Programming unit: 128 bytes →	H'00707F
				-----	H'007FFF
EB8 Erase unit 32 kbytes	H'008000	H'008001	H'008002	← Programming unit: 128 bytes →	H'00807F
				-----	H'00FFFF

				-----	H'05FFFF

Figure 19.5 384-kbyte Flash Memory Block Configuration (Modes 3, 4, and 7)

19.4 Input/Output Pins

The flash memory is controlled by means of the pins shown in table 19.2.

Table 19.2 Pin Configuration

Pin Name	I/O	Function
RES	Input	Reset
MD2	Input	Sets this LSI's operating mode
MD1	Input	Sets this LSI's operating mode
MD0	Input	Sets this LSI's operating mode
P52	Input	Sets operating mode in programmer mode
P51	Input	Sets operating mode in programmer mode
P50	Input	Sets operating mode in programmer mode
TxD1	Output	Serial transmit data output
RxD1	Input	Serial receive data input

19.5 Register Descriptions

The flash memory has the following registers. For details on the system control register, refer to section 3.2.2, System Control Register (SYSCR).

- Flash memory control register 1 (FLMCR1)
- Flash memory control register 2 (FLMCR2)
- Erase block register 1 (EBR1)
- Erase block register 2 (EBR2)
- RAM emulation register (RAMER)

19.5.1 Flash Memory Control Register 1 (FLMCR1)

FLMCR1 is a register that makes the flash memory transit to program mode, program-verify mode, erase mode, or erase-verify mode. For details on register setting, refer to section 19.8, Flash Memory Programming/Erasing.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0/1	R	This bit is reserved. This bit is always read as 0 in modes 1 and 2. This bit is always read as 1 in modes 3 to 7.
6	SWE	0	R/W	Software Write Enable When this bit is set to 1, flash memory programming/erasing is enabled. When this bit is cleared to 0, other FLMCR1 register bits and all EBR1 and EBR2 bits cannot be set.
5	ESU	0	R/W	Erase Setup When this bit is set to 1 while SWE = 1, the flash memory transits to the erase setup state. When it is cleared to 0, the erase setup state is cancelled.
4	PSU	0	R/W	Program Setup When this bit is set to 1 while SWE = 1, the flash memory transits to the program setup state. When it is cleared to 0, the program setup state is cancelled.
3	EV	0	R/W	Erase-Verify When this bit is set to 1 while SWE = 1, the flash memory transits to erase-verify mode. When it is cleared to 0, erase-verify mode is cancelled.
2	PV	0	R/W	Program-Verify When this bit is set to 1 while SWE = 1, the flash memory transits to program-verify mode. When it is cleared to 0, program-verify mode is cancelled.
1	E	0	R/W	Erase When this bit is set to 1 while SWE = 1, and ESU = 1, the flash memory transits to erase mode. When it is cleared to 0, erase mode is cancelled.

Bit	Bit Name	Initial Value	R/W	Description
0	P	0	R/W	Program When this bit is set to 1 while SWE = 1, and PSU = 1, the flash memory transits to program mode. When it is cleared to 0, program mode is cancelled.

19.5.2 Flash Memory Control Register 2 (FLMCR2)

FLMCR2 is a register that displays the state of flash memory programming/erasing. When the SWE bit in FLMCR1 is cleared to 0, FLMCR2 is initialized to H'00. FLMCR2 is a read-only register, and should not be written to.

Bit	Bit Name	Initial Value	R/W	Description
7	FLER	0	R	Indicates that an error has occurred during an operation on flash memory (programming or erasing). When FLER is set to 1, flash memory goes to the error-protection state. See section 19.9.3, Error Protection, for details.
6 to 0	—	0	R	Reserved These bits always read 0.

19.5.3 Erase Block Register 1 (EBR1)

EBR1 specifies the flash memory erase area block. EBR1 is initialized to H'00 when the SWE bit in FLMCR1 is 0. Set only one bit in EBR1 and EBR2 together (do not set more than one bit at the same time). Setting more than one bit will automatically clear all EBR1 and EBR2 bits to 0. For details, see table 19.3.

Bit	Bit Name	Initial Value	R/W	Description
7	EB7	0	R/W	When this bit is set to 1, 4 kbytes of EB7 are to be erased.
6	EB6	0	R/W	When this bit is set to 1, 4 kbytes of EB6 are to be erased.
5	EB5	0	R/W	When this bit is set to 1, 4 kbytes of EB5 are to be erased.
4	EB4	0	R/W	When this bit is set to 1, 4 kbytes of EB4 are to be erased.
3	EB3	0	R/W	When this bit is set to 1, 4 kbytes of EB3 are to be erased.
2	EB2	0	R/W	When this bit is set to 1, 4 kbytes of EB2 are to be erased.
1	EB1	0	R/W	When this bit is set to 1, 4 kbytes of EB1 are to be erased.
0	EB0	0	R/W	When this bit is set to 1, 4 kbytes of EB0 are to be erased.

19.5.4 Erase Block Register 2 (EBR2)

EBR2 specifies the flash memory erase area block. EBR2 is initialized to H'00 when the SWE bit in FLMCR1 is 0. Set only one bit in EBR2 and EBR1 together (do not set more than one bit at the same time). Setting more than one bit will automatically clear all EBR1 and EBR2 bits to 0. For details, see table 19.3.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	0	R/W	Reserved The initial value should not be changed.
5	EB13	0	R/W	When this bit is set to 1, 64 kbytes of EB13 are to be erased.
4	EB12	0	R/W	When this bit is set to 1, 64 kbytes of EB12 are to be erased.
3	EB11	0	R/W	When this bit is set to 1, 64 kbytes of EB11 are to be erased.
2	EB10	0	R/W	When this bit is set to 1, 64 kbytes of EB10 are to be erased.
1	EB9	0	R/W	When this bit is set to 1, 64 kbytes of EB9 are to be erased.
0	EB8	0	R/W	When this bit is set to 1, 32 kbytes of EB8 are to be erased.

Table 19.3 Erase Blocks

Block (Size)	Address
	Modes 3, 4, and 7
EB0 (4 kbytes)	H'000000 to H'000FFF
EB1 (4 kbytes)	H'001000 to H'001FFF
EB2 (4 kbytes)	H'002000 to H'002FFF
EB3 (4 kbytes)	H'003000 to H'003FFF
EB4 (4 kbytes)	H'004000 to H'004FFF
EB5 (4 kbytes)	H'005000 to H'005FFF
EB6 (4 kbytes)	H'006000 to H'006FFF
EB7 (4 kbytes)	H'007000 to H'007FFF
EB8 (32 kbytes)	H'008000 to H'00FFFF
EB9 (64 kbytes)	H'010000 to H'01FFFF
EB10 (64 kbytes)	H'020000 to H'02FFFF
EB11 (64 kbytes)	H'030000 to H'03FFFF
EB12 (64 kbytes)	H'040000 to H'04FFFF
EB13 (64 kbytes)	H'050000 to H'05FFFF

19.5.5 RAM Emulation Register (RAMER)

Note: This function is not supported by the H8S/2367 or H8S/2366.

RAMER specifies the area of flash memory to be overlapped with part of RAM when emulating real-time flash memory programming. RAMER settings should be made in user mode or user program mode. To ensure correct operation of the emulation function, the ROM for which RAM emulation is performed should not be accessed immediately after this register has been modified. Normal execution of an access immediately after register modification is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	R	Reserved These bits always read 0.
3	RAMS	0	R/W	RAM Select Specifies selection or non-selection of flash memory emulation in RAM. When RAMS = 1, the flash memory is overlapped with part of RAM, and all flash memory block are in the program/erase-protect state. When this bit is cleared to 0, the RAM emulation function is invalid.
2	RAM2	0	R/W	Flash Memory Area Selection
1	RAM1	0	R/W	When the RAMS bit is set to 1, selects one of the following flash memory areas to overlap the RAM area. The areas correspond with 4-kbyte erase blocks. Modes 3, 4, and 7 000: H'000000 to H'000FFF (EB0) 001: H'001000 to H'001FFF (EB1) 010: H'002000 to H'002FFF (EB2) 011: H'003000 to H'003FFF (EB3) 100: H'004000 to H'004FFF (EB4) 101: H'005000 to H'005FFF (EB5) 110: H'006000 to H'006FFF (EB6) 111: H'007000 to H'007FFF (EB7)
0	RAM0	0	R/W	

19.6 On-Board Programming Modes

In an on-board programming mode, programming, erasing, and verification for the on-chip flash memory can be performed. There are two on-board programming modes: boot mode and user program mode. Table 19.4 shows how to select boot mode. User program mode can be selected by setting the control bits by software. For a diagram that shows mode transitions of flash memory, see figure 19.2.

Table 19.4 Setting On-Board Programming Mode

Mode Setting		MD2	MD1	MD0
Boot mode	Single-chip activation expanded mode with on-chip ROM enabled	0	1	1

19.6.1 Boot Mode

When this LSI enters boot mode, the embedded boot program is started. The boot program transfers the programming control program from the externally connected host to the on-chip RAM via the SCI_1. When the flash memory is all erased, the programming control program is executed.

Table 19.5 shows the boot mode operations between reset end and branching to the programming control program.

1. When the boot program is initiated, the SCI_1 should be set to asynchronous mode, the chip measures the low-level period of asynchronous SCI communication data (H'00) transmitted continuously from the host. The chip then calculates the bit rate of transmission from the host, and adjusts the SCI_1 bit rate to match that of the host. The transfer format is 8-bit data, 1 stop bit, and no parity. The reset should end with the RxD pin high. The RxD and TxD pins should be pulled up on the board if necessary. After the reset ends, it takes approximately 100 states before the chip is ready to measure the low-level period.
2. After matching the bit rates, the chip transmits one H'00 byte to the host to indicate the end of bit rate adjustment. The host should confirm that this adjustment end indication (H'00) has been received normally, and transmit one H'55 byte to the chip. If reception could not be performed normally, initiate boot mode again by a reset. Depending on the host's transfer bit rate and system clock frequency of this LSI, there will be a discrepancy between the bit rates of the host and the chip. To operate the SCI properly, set the host's transfer bit rate and system clock frequency of this LSI within the ranges listed in table 19.6.
3. When boot mode is used, the flash memory programming control program must be prepared in the host beforehand. Prepare a programming control program in accordance with the description in section 19.8, Flash Memory Programming/Erasing.
4. Before branching to the programming control program, the chip terminates transfer operations by the SCI_1 (by clearing the RE and TE bits in SCR to 0), but the adjusted bit rate value remains set in BRR. Therefore, the programming control program can still use it for transfer of program data or verify data with the host. The TxD pin is high. The contents of the CPU general registers are undefined immediately after branching to the programming control program. These registers must be initialized at the beginning of the programming control program, since the stack pointer (SP), in particular, is used implicitly in subroutine calls, etc.
5. In boot mode, if flash memory contains data (all data is not 1), all blocks of flash memory are erased. Boot mode is used for the initial programming in the on-board state or for a forcible return when a program that is to be initiated in user program mode was accidentally erased and could not be executed in user program mode.

Notes: 1. In boot mode, a part of the on-chip RAM area (H'FF8000 to H'FF87FF) is used by the boot program. Addresses H'FF8800 to H'FFBFFF is the area to which the programming control program is transferred from the host. The boot program area cannot be used until the execution state in boot mode switches to the programming control program.

2. Boot mode can be cleared by a reset. Release the reset by setting the MD pins, after waiting at least 20 states since driving the reset pin low. Boot mode is also cleared when the WDT overflow reset occurs.
3. Do not change the MD pin input levels in boot mode.
4. All interrupts are disabled during programming or erasing of the flash memory.

Table 19.5 Boot Mode Operation

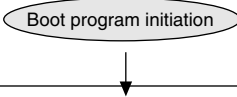

Item	Host Operation	Communication Contents	LSI Operation
	Processing Contents		Processing Contents
Boot mode initiation			<p>Branches to boot program at reset-start.</p> <p style="text-align: center;">  </p>

			<p style="text-align: center;">↓</p> <p>Branches to programming control program transferred to on-chip RAM and starts execution.</p>

Table 19.6 System Clock Frequencies for which Automatic Adjustment of LSI Bit Rate is Possible

Host Bit Rate	System Clock Frequency Range of LSI
19,200 bps	8 to 25 MHz
9,600 bps	8 to 25 MHz

19.6.2 User Program Mode

On-board programming/erasing of an individual flash memory block can also be performed in user program mode by branching to a user program/erase program. The user must set branching conditions and provide on-board means of supplying programming data. The flash memory must contain the program/erase program or a program which provides the program/erase program from external memory. Because the flash memory itself cannot be read during programming/erasing, transfer the program/erase program to on-chip RAM, as like in boot mode. Figure 19.6 shows a sample procedure for programming/erasing in user program mode. Prepare a program/erase program in accordance with the description in section 19.8, Flash Memory Programming/Erasing.

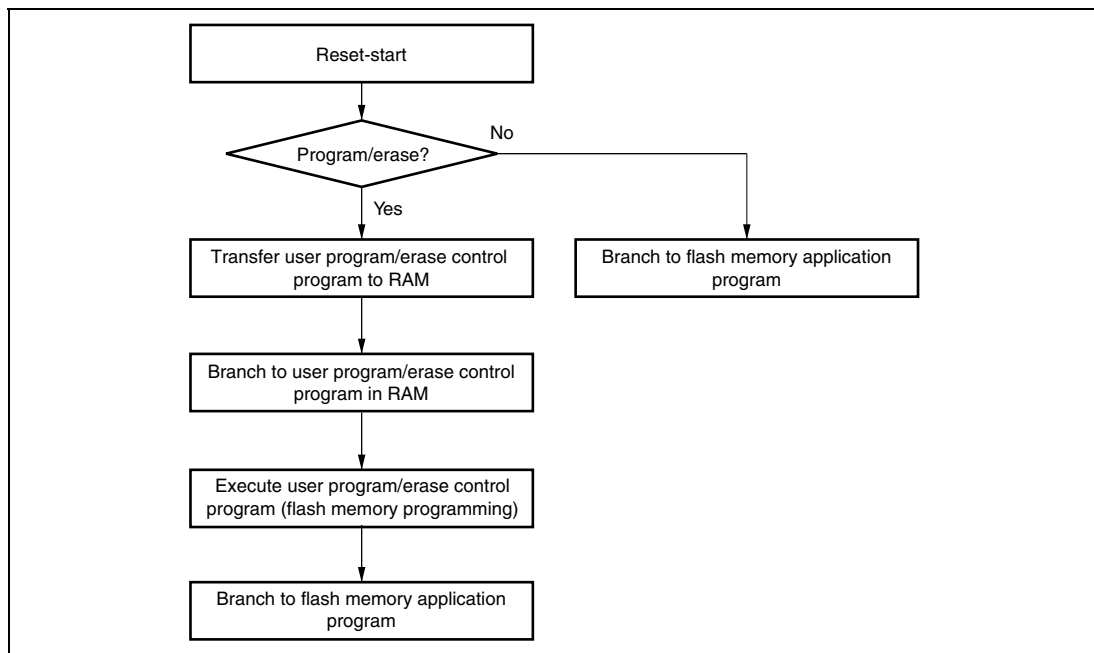

Figure 19.6 Programming/Erasing Flowchart Example in User Program Mode

19.7 Flash Memory Emulation in RAM

Note: This function is not supported by the H8S/2367 or H8S/2366.

Making a setting in the RAM emulation register (RAMER) enables RAM to be overlapped onto the part of flash memory area so that data to be programmed to flash memory can be emulated in the on-chip RAM in real time. Emulation can be performed in user mode or user program mode. Figure 19.7 shows an example of emulation of real-time flash memory programming.

1. Set RAMER to overlap RAM onto the area for which real-time programming is required.
2. Emulation is performed using the overlapping RAM.
3. After the program data has been confirmed, the RAMS bit is cleared, thus releasing RAM overlap.
4. The data written in the overlapping RAM is written into the flash memory space (EB0).

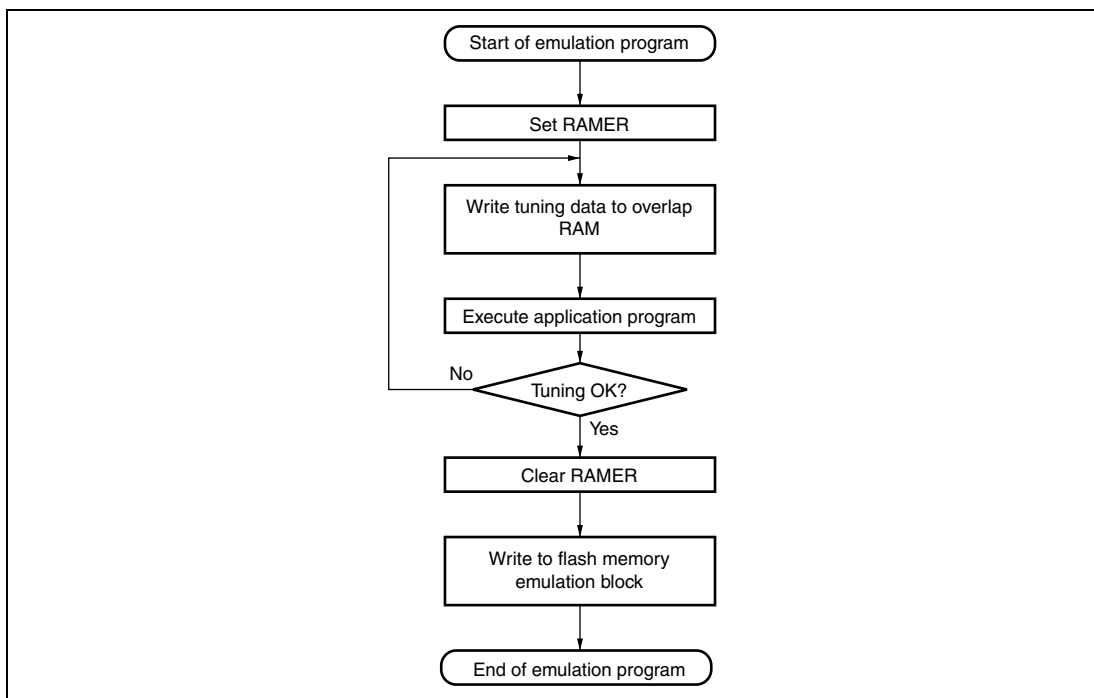

Figure 19.7 Flowchart for Flash Memory Emulation in RAM

Example in which flash memory block is overlapped is shown in figure 19.8.

1. The RAM area to be overlapped is fixed at a 4-kbyte area in the range of H'FFA000 to H'FFAFFF.

2. The flash memory area to overlap is selected by RAMER from a 4-kbyte area among one of the EB0 to EB7 blocks.
3. The overlapped RAM area can be accessed from both the flash memory addresses and RAM addresses.

- Notes:
1. When the RAMS bit in RAMER is set to 1, program/erase protection is enabled for all flash memory blocks (emulation protection). In this state, setting the P or E bit in FLMCR1 to 1 does not cause a transition to program mode or erase mode.
 2. A RAM area cannot be erased by execution of software in accordance with the erase algorithm.
 3. Block area EB0 contains the vector table. When performing RAM emulation, the vector table is needed in the overlap RAM.
 4. This function is not supported by the H8S/2367 or H8S/2366.

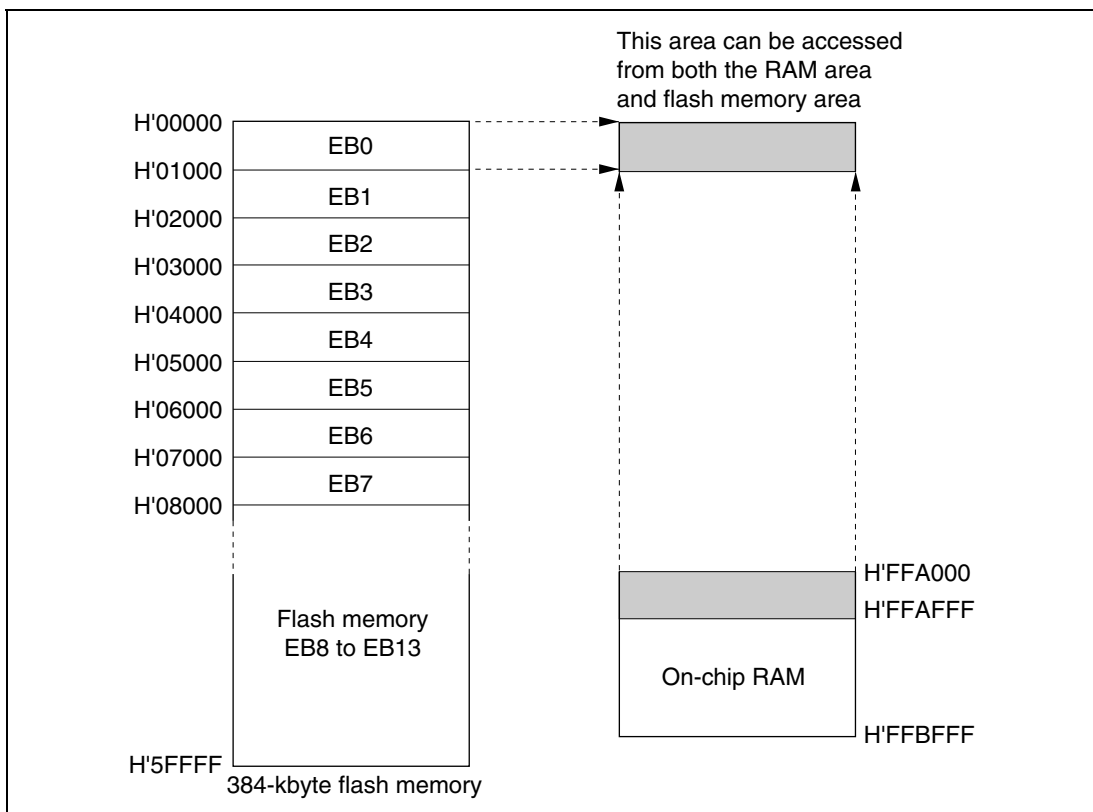

Figure 19.8 Example of RAM Overlap Operation

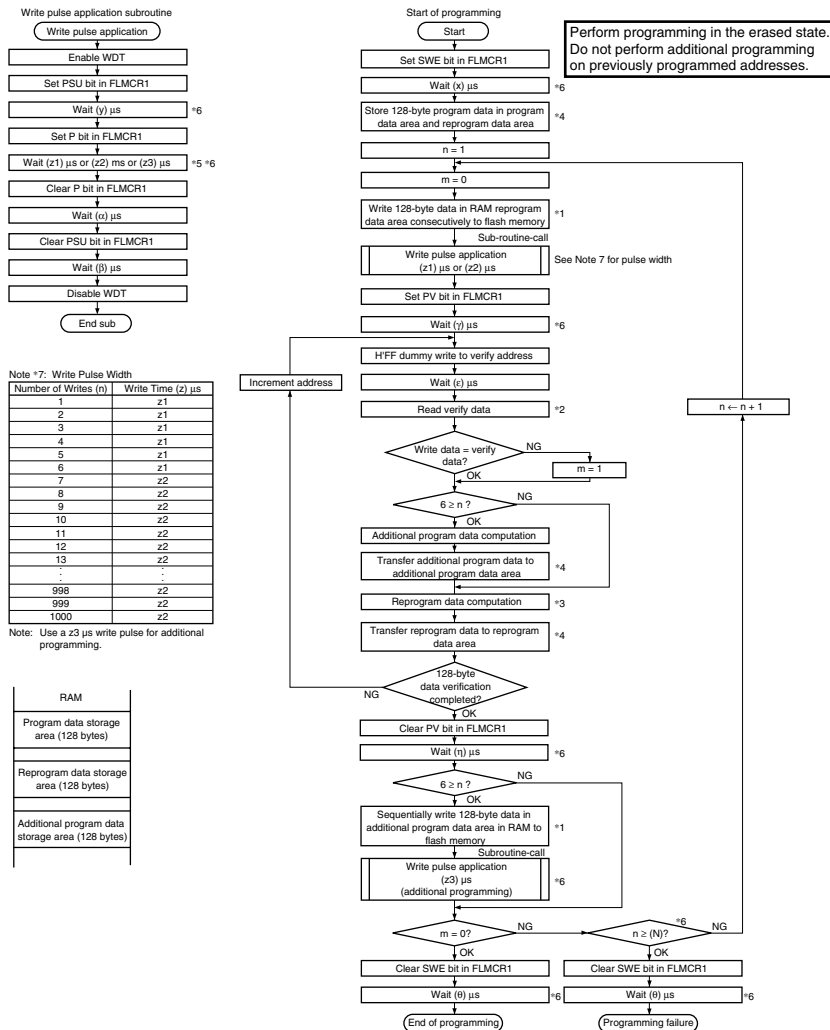

19.8 Flash Memory Programming/Erasing

A software method, using the CPU, is employed to program and erase flash memory in the on-board programming modes. Depending on the FLMCR1 and FLMCR2 setting, the flash memory operates in one of the following four modes: program mode, erase mode, program-verify mode, and erase-verify mode. The programming control program in boot mode and the user program/erase program in user mode use these operating modes in combination to perform programming/erasing. Flash memory programming and erasing should be performed in accordance with the descriptions in section 19.8.1, Program/Program-Verify and section 19.8.2, Erase/Erase-Verify, respectively.

19.8.1 Program/Program-Verify

When programming data or programs to the flash memory, the program/program-verify flowchart shown in figure 19.9 should be followed. Performing programming operations according to this flowchart will enable data or programs to be programmed to the flash memory without subjecting the chip to voltage stress or sacrificing program data reliability.

1. Programming must be done to an empty address. Do not reprogram an address to which programming has already been performed.
2. Programming should be carried out 128 bytes at a time. A 128-byte data transfer must be performed even if programming fewer than 128 bytes. In this case, H'FF data must be written to the extra addresses.
3. Prepare the following data storage areas in RAM: a 128-byte programming data area, a 128-byte reprogramming data area, and a 128-byte additional-programming data area. Perform reprogramming data computation and additional programming data computation according to figure 19.9.
4. Consecutively transfer 128 bytes of data in byte units from the programming data area, reprogramming data area, or additional-programming data area to the flash memory. The program address and 128-byte data are latched in the flash memory. The lower 8 bits of the start address in the flash memory destination area must be H'00 or H'80.
5. The time during which the P bit is set to 1 is the programming time. Figure 19.9 shows the allowable programming times.
6. The watchdog timer (WDT) is set to prevent overprogramming due to program runaway, etc. Set a value greater than $(y + z2 + \alpha + \beta) \mu s$ as the WDT overflow period.
7. For a dummy write to a verify address, write 1-byte data H'FF to an address whose lower 2 bits are B'00. Verify data can be read in words from the address to which a dummy write was performed.
8. The maximum number of repetitions of the program/program-verify sequence to the same bit (N) must not be exceeded.

- Notes: *1 Data transfer is performed by byte transfer. The lower 8 bits of the first address written to must be H'00 or H'80. A 128-byte data transfer must be performed even if writing fewer than 128 bytes; in this case, HFF data must be written to the extra addresses.
- *2 Verify data is read in 16-bit (W) units.
- *3 The reprogram data is given by the operation of the following tables (comparison between stored data in the program data area and verify data). Programming is executed for the bits of reprogram data 0 in the next reprogram loop. Even bits for which programming has been completed will be subjected to additional programming if they fail the subsequent verify operation.
- *4 A 128-byte areas for storing program data, reprogram data, and additional program data must be provided in the RAM. The contents of the reprogram and additional program data are modified as programming proceeds.
- *5 A write pulse of (z1) or (z2) μs should be applied according to the progress of the programming operation. See Note *7 for the pulse widths. When writing of additional-programming data is executed, a (z3) μs write pulse should be applied.
- *6 For the values of x, y, z1, z2, z3, α, β, γ, ε, η, θ, and N, see section 24.3, Flash Memory Characteristics.

Program Data Operation Chart

Original Data (D)	Verify Data (V)	Reprogram Data (X)	Comments
0	0	1	Programming completed
1	1	0	Programming incomplete; reprogram
1	0	1	Still in erased state; no action

Additional Program Data Operation Chart

Reprogram Data (X)	Verify Data (V)	Additional Program Data (Y)	Comments
0	0	0	Additional programming executed
1	1	1	Additional programming not executed
1	0	0	Additional programming not executed
1	1	1	Additional programming not executed

Figure 19.9 Program/Program-Verify Flowchart

19.8.2 Erase/Erase-Verify

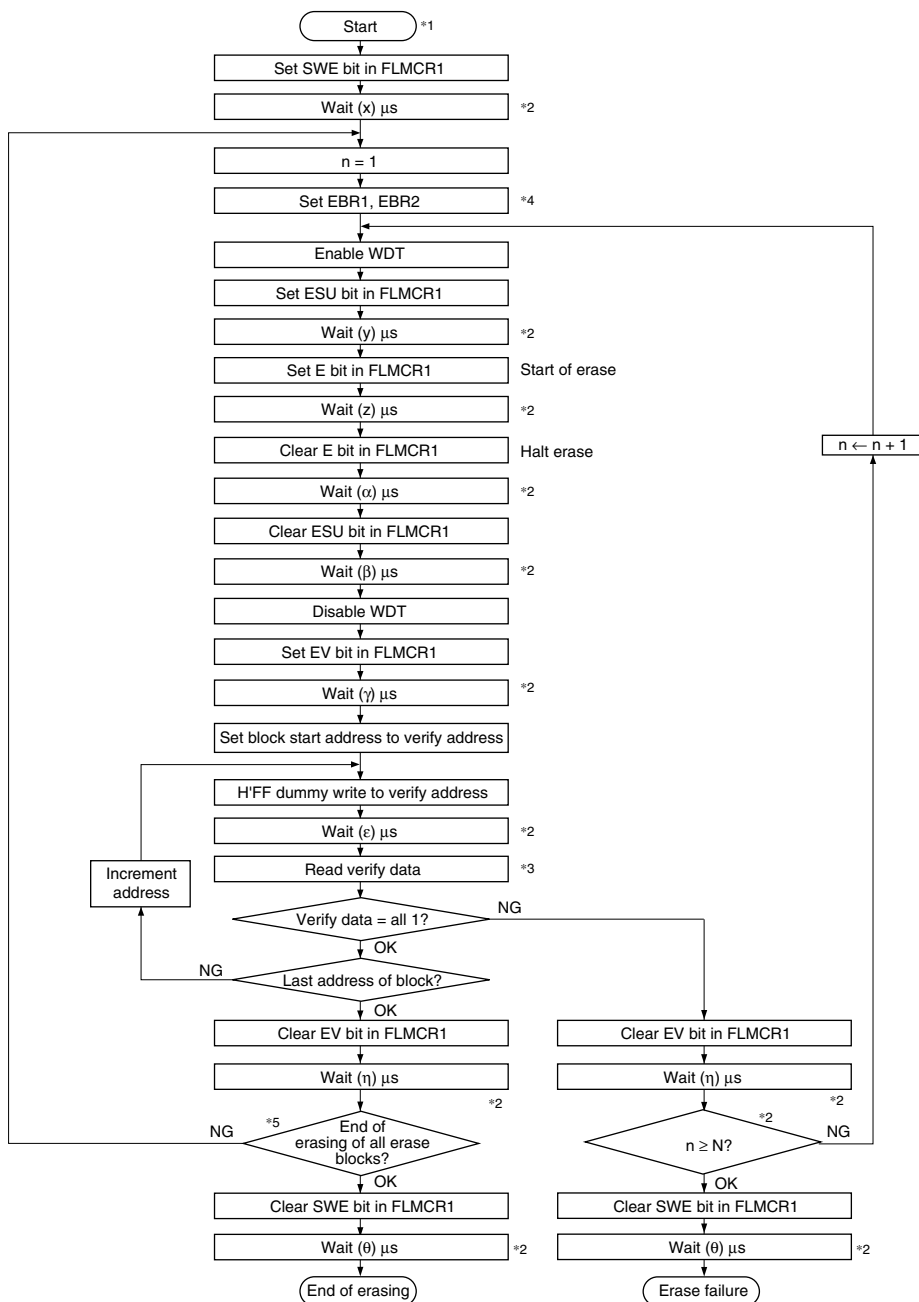

When erasing flash memory, the erase/erase-verify flowchart shown in figure 19.10 should be followed.

1. Prewriting (setting erase block data to all 0s) is not necessary.
2. Erasing is performed in block units. Make only a single-bit specification in the erase block registers (EBR1 and EBR2). To erase multiple blocks, each block must be erased in turn.
3. The time during which the E bit is set to 1 is the flash memory erase time.
4. The watchdog timer (WDT) is set to prevent overerasing due to program runaway, etc. Set a value greater than $(y + z + \alpha + \beta)$ ms as the WDT overflow period.
5. For a dummy write to a verify address, write 1-byte data H'FF to an address whose lower two bits are B'00. Verify data can be read in longwords from the address to which a dummy write was performed.
6. If the read data is not erased, set erase mode again, and repeat the erase/erase-verify sequence as before. The maximum number of repetitions of the erase/erase-verify sequence (N) must not be exceeded.

19.8.3 Interrupt Handling when Programming/Erasing Flash Memory

All interrupts, including NMI input, are disabled when flash memory is being programmed or erased, and while the boot program is executing in boot mode. There are three reasons for this:

1. Interrupt during programming or erasing might cause a violation of the programming or erasing algorithm, with the result that normal operation could not be assured.
2. If the interrupt exception handling is started when the vector address has not been programmed yet or the flash memory is being programmed or erased, the vector would not be read correctly, possibly resulting in CPU runaway.
3. If an interrupt occurred during boot program execution, it would not be possible to execute the normal boot mode sequence.

Notes: *1 Prewriting (setting erase block data to all 0) is not necessary.

*2 The values of x, y, z, α, β, γ, ε, η, θ, and N are shown in section 24.3, Flash Memory Characteristics.

*3 Verify data is read in 16-bit (W) units.

*4 Set only one bit in EBR1 or EBR2. More than one bit cannot be set.

*5 Erasing is performed in block units. To erase a number of blocks, the individual blocks must be erased sequentially.

Figure 19.10 Erase/Eraser-Verify Flowchart

19.9 Program/Erase Protection

There are three kinds of flash memory program/erase protection: hardware protection, software protection, and error protection.

19.9.1 Hardware Protection

Hardware protection refers to a state in which programming/erasing of flash memory is forcibly disabled or aborted because of a transition to reset (including an overflow reset by the WDT) or standby mode. Flash memory control register 1 (FLMCR1), flash memory control register 2 (FLMCR2), erase block register 1 (EBR1), and erase block register 2 (EBR2) are initialized. In a reset via the $\overline{\text{RES}}$ pin, the reset state is not entered unless the $\overline{\text{RES}}$ pin is held low until oscillation stabilizes after powering on. In the case of a reset during operation, hold the $\overline{\text{RES}}$ pin low for the $\overline{\text{RES}}$ pulse width specified in the AC Characteristics section.

19.9.2 Software Protection

Protection can be implemented against programming/erasing of all flash memory blocks by clearing the SWE bit in FLMCR1 to 0 or setting the RAMS bit in the RAM emulation register (RAMER) to 1 (emulation protection) by software (these operations must be executed in the on-chip RAM or external memory). When protection is in effect, setting the P or E bit in FLMCR1 does not cause a transition to program mode or erase mode. By setting the erase block register 1 (EBR1) and erase block register 2 (EBR2), erase protection can be set for individual blocks. When EBR1 and EBR2 are set to H'00, erase protection is set for all blocks.

19.9.3 Error Protection

In error protection, an error is detected when the CPU's runaway occurs during flash memory programming/erasing, or operation is not performed in accordance with the program/erase algorithm, and the program/erase operation is forcibly aborted. Aborting the program/erase operation prevents damage to the flash memory due to overprogramming or overerasing.

When the following errors are detected during programming/erasing of flash memory, the FLER bit in FLMCR2 is set to 1, and the error protection state is entered.

- When flash memory is read during programming/erasing (including a vector read or instruction fetch)
- When an exception handling (excluding a reset) is started during programming/erasing
- When a SLEEP instruction is executed during programming/erasing
- When the CPU releases the bus during programming/erasing

The FLMCR1, FLMCR2, EBR1, and EBR2 settings are retained, but program mode or erase mode is forcibly aborted at the point at which the error occurred. Program mode or erase mode

cannot be re-entered by re-setting the P or E bit. However, since PV and EV bit setting is enabled, and a transition can be made to verify mode. The error protection state can be canceled by a reset or in hardware standby mode.

19.10 Programmer Mode

In programmer mode, a PROM programmer can perform programming/erasing via a socket adapter, just like for a discrete flash memory. Use a PROM programmer which supports the Renesas 512-kbyte flash memory on-chip MCU device type (FZTAT512V3A). A 12-MHz input clock is needed.

19.11 Power-Down States for Flash Memory

In user mode, the flash memory will operate in either of the following states:

- Normal operating mode
The flash memory can be read.
- Standby mode
All flash memory circuits are halted.

Table 19.7 shows the correspondence between the operating modes of this LSI and the flash memory. When the flash memory returns to normal operation from a standby state, a power supply circuit stabilization period is needed. When the flash memory returns to its normal operating state, bits STS3 to STS0 in SBYCR must be set to provide a wait time of at least 100 μ s, even when the external clock is being used.

Table 19.7 Flash Memory Operating States

Operating Mode	Flash Memory Operating State
Active mode	Normal operating state
Sleep mode	Normal operating state
Standby mode	Standby state

19.12 Usage Notes

Precautions concerning the use of on-board programming mode, the RAM emulation function, and programmer mode are summarized below.

1. Use the specified voltages and timing for programming and erasing.
Applied voltages in excess of the rating can permanently damage the device. Use a PROM programmer that supports the Renesas microcomputer device type with 512-kbyte on-chip flash memory (FZTAT512V3A).

Do not select the HN27C4096 setting for the PROM programmer, and only use the specified socket adapter.

2. Reset the flash memory before turning on/off the power.

When applying or disconnecting Vcc power, fix the $\overline{\text{RES}}$ pin low and place the flash memory in the hardware protection state. The power-on and power-off timing requirements should also be satisfied in the event of a power failure and subsequent recovery.

3. Use the recommended algorithm when programming and erasing flash memory.

The recommended algorithm enables programming and erasing to be carried out without subjecting the device to voltage stress or sacrificing program data reliability. When setting the P or E bit in FLMCR1, the watchdog timer should be set beforehand as a precaution against program runaway, etc.

4. Do not set or clear the SWE bit during execution of a program in flash memory.

Wait for at least 100 μs after clearing the SWE bit before executing a program or reading data in flash memory.

When the SWE bit is set, data in flash memory can be rewritten. When the SWE bit is set to 1, data in flash memory can be read only in program-verify/erase-verify mode. Access flash memory only for verify operations (verification during programming/erasing). Also, do not clear the SWE bit during programming, erasing, or verifying. Similarly, when using the RAM emulation function, the SWE bit must be cleared before executing a program or reading data in flash memory.

However, the RAM area overlapping flash memory space can be read and written to regardless of whether the SWE bit is set or cleared.

5. Do not use interrupts while flash memory is being programmed or erased.

All interrupt requests, including NMI, should be disabled during programming/erasing the flash memory to give priority to program/erase operations.

6. Do not perform additional programming. Erase the memory before reprogramming.

In on-board programming, perform only one programming operation on a 128-byte programming unit block. In programmer mode, too, perform only one programming operation on a 128-byte programming unit block. Programming should be carried out with the entire programming unit block erased.

7. Before programming, check that the chip is correctly mounted in the PROM programmer.

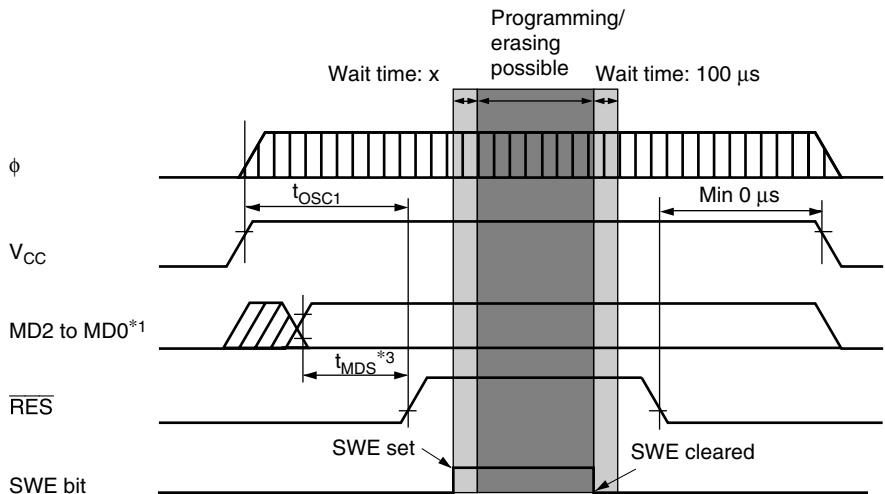

Overcurrent damage to the device can result if the index marks on the PROM programmer socket, socket adapter, and chip are not correctly aligned.

8. Do not touch the socket adapter or chip during programming.

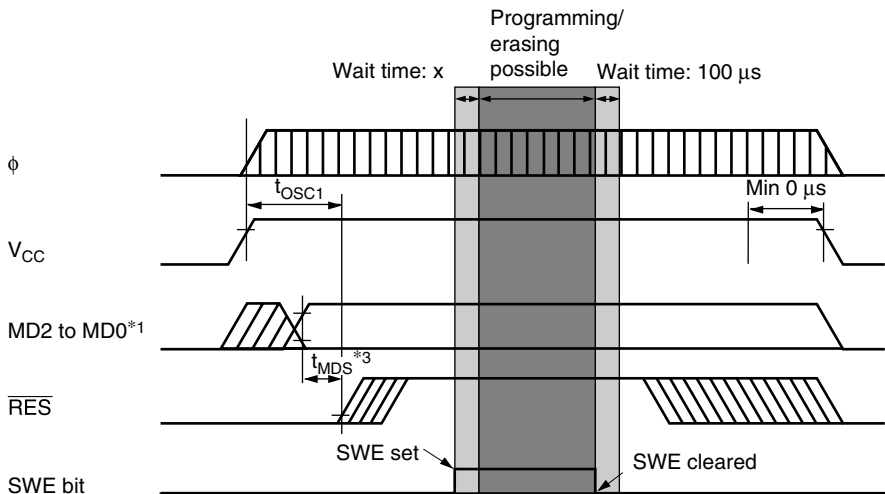

Touching either of these can cause contact faults and write errors.

9. Apply the reset signal after the SWE, bit is cleared during its operation.

The reset signal is applied at least 100 μs after the SWE bit has been cleared.

(1) Boot Mode

(2) User Program Mode

Period during which flash memory access is prohibited
(x: Wait time after setting SWE bit)*2

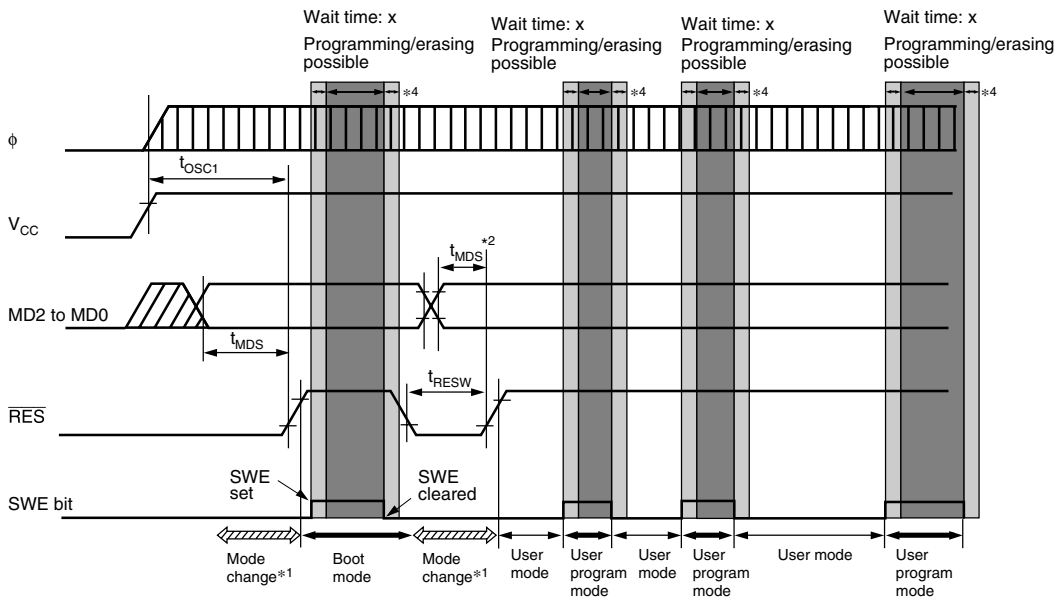

Period during which flash memory can be programmed
(Execution of program in flash memory prohibited, and data reads other than verify operations prohibited)

Notes: *1 Except when switching modes, the level of the mode pins (MD2 to MD0) must be fixed until power-off by pulling the pins up or down.

*2 See section 24.3, Flash Memory Characteristics.

*3 Mode programming setup time t_{MDS} (min) = 200 ns

Figure 19.11 Power-On/Off Timing

Period during which flash memory access is prohibited
(x: Wait time after setting SWE bit)*3

Period during which flash memory can be programmed
(Execution of program in flash memory prohibited, and data reads other than verify operations prohibited)

Notes: *1 When entering boot mode or making a transition from boot mode to another mode, mode switching must be carried out by means of \overline{RES} input. The state of ports with multiplexed address functions and bus control output pins (\overline{AS} , \overline{RD} , \overline{HWR} , \overline{LWR}) will change during this switchover interval (the interval during which the \overline{RES} pin input is low), and therefore these pins should not be used as output signals during this time.

*2 When making a transition from boot mode to another mode, a mode programming setup time t_{MDS} (min) of 200 ns is necessary with respect to \overline{RES} clearance timing.

*3 See section 24.3, Flash Memory Characteristics.

*4 Wait time: 100 μ s

Figure 19.12 Mode Transition Timing
(Example: Boot Mode \rightarrow User Mode \leftrightarrow User Program Mode)

Section 20 Mask ROM

The LSI of this series has 256 kbytes of mask ROM. The on-chip ROM is connected to the CPU, data transfer controller (DTC), and DMA controller (DMAC)* with a 16-bit data bus. The on-chip ROM can be accessed by the CPU, DTC, and DMAC in 8 or 16-bit units. The data in the on-chip ROM can always be accessed in one state.

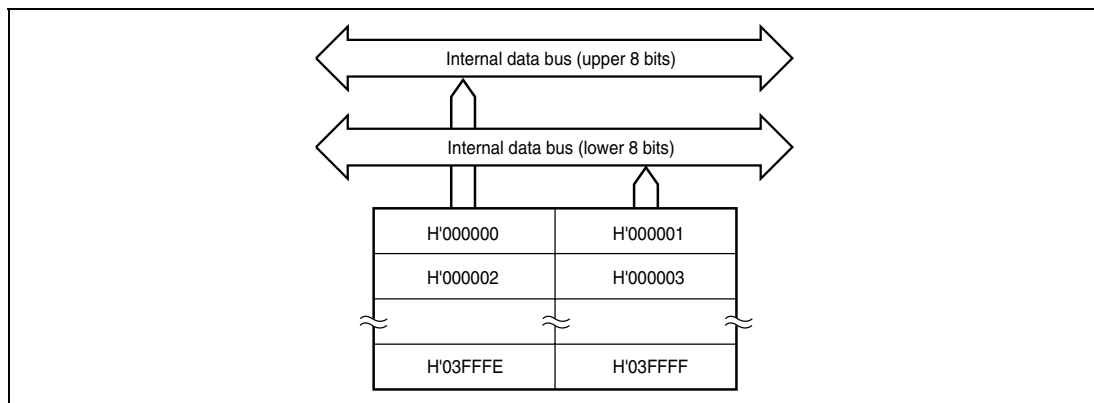

Figure 20.1 Block Diagram of 256-kbyte Mask ROM (HD6432365)

The on-chip ROM is enabled or disabled according to the operating mode. The operating mode is selected by the mode setting pins MD2 to MD0 as shown in table 3.1. Select mode 4 or 7 when the on-chip ROM is used, and mode 1 or 2 when the on-chip ROM is not used. The on-chip ROM is allocated in area 0.

Note: * Not supported by the H8S/2366.

Section 21 Clock Pulse Generator

This LSI has an on-chip clock pulse generator (CPG) that generates the system clock (ϕ) and internal clocks.

The clock pulse generator consists of an oscillator circuit, PLL circuit, and divider.

Figure 21.1 shows a block diagram of the clock pulse generator.

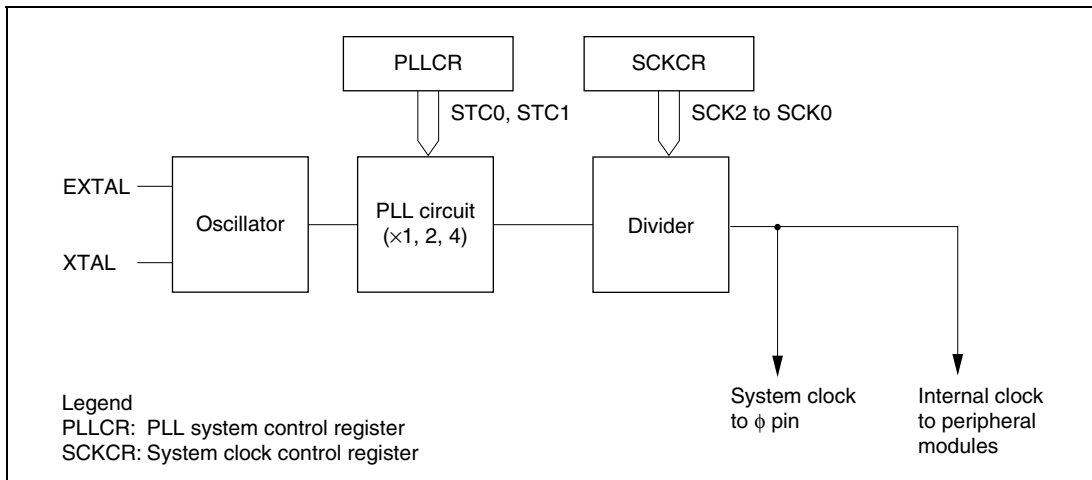

Figure 21.1 Block Diagram of Clock Pulse Generator

The frequency can be changed by means of the PLL circuit. Frequency changes are made by software by means of settings in the PLL control register (PLLCR) and the system clock control register (SCKCR).

21.1 Register Descriptions

The clock pulse generator has the following registers.

- System clock control register (SCKCR)
- PLL control register (PLLCR)

21.1.1 System Clock Control Register (SCKCR)

SCKCR controls ϕ clock output and selects operation when the frequency multiplication factor used by the PLL circuit is changed, and the division ratio used by the divider.

Bit	Bit Name	Initial Value	R/W	Description
7	PSTOP	0	R/W	<p>ϕ Clock Output Disable</p> <p>Controls ϕ output.</p> <p>Normal Operation</p> <p>0: ϕ output</p> <p>1: Fixed high</p> <p>Sleep Mode</p> <p>0: ϕ output</p> <p>1: Fixed high</p> <p>Software Standby Mode</p> <p>0: Fixed high</p> <p>1: Fixed high</p> <p>Hardware Standby Mode</p> <p>0: High impedance</p> <p>1: High impedance</p> <p>All module clock stop mode</p> <p>0: ϕ output</p> <p>1: Fixed high</p>
6	—	0	R/W	<p>Reserved</p> <p>Though this bit can be read from or written to, the write value should always be 0.</p>
5	—	0	—	Reserved
4	—	0	—	These bits are always read as 0 and cannot be modified.
3	STCS	0	R/W	<p>Frequency Multiplication Factor Switching Mode Select</p> <p>Selects the operation when the PLL circuit frequency multiplication factor is changed.</p> <p>0: Specified multiplication factor is valid after transition to software standby mode</p> <p>1: Specified multiplication factor is valid immediately after STC1 and STC0 bits are rewritten</p>

Bit	Bit Name	Initial Value	R/W	Description
2	SCK2	0	R/W	System Clock Select 2 to 0
1	SCK1	0	R/W	Select the division ratio.
0	SCK0	0	R/W	000: 1/1 001: 1/2 010: 1/4 011: Setting prohibited 100: Setting prohibited 101: Setting prohibited 11X: Setting prohibited

X: Don't care

21.1.2 PLL Control Register (PLLCR)

PLLCR sets the frequency multiplication factor used by the PLL circuit.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	0	—	Reserved These bits are always read as 0 and cannot be modified.
3	—	0	R/W	Reserved Though this bit can be read from or written to, the write value should always be 0.
2	—	0	R/W	Reserved This bit is always read as 0 and cannot be modified.
1	STC1	0	R/W	Frequency Multiplication Factor
0	STC0	0	R/W	The STC bits specify the frequency multiplication factor used by the PLL circuit. 00: $\times 1$ 01: $\times 2$ 10: $\times 4$ 11: Setting prohibited

21.2 Oscillator

Clock pulses can be supplied by connecting a crystal resonator, or by input of an external clock.

21.2.1 Connecting a Crystal Oscillator

A crystal oscillator can be connected as shown in the example in figure 21.2. Select the damping resistance R_d according to table 21.1. An AT-cut parallel-resonance type should be used.

When a clock is supplied with a crystal resonator connected, the frequency of the crystal resonator should be 8 MHz to 25 MHz.

Figure 21.3 shows the equivalent circuit of the crystal oscillator. Use a crystal oscillator that has the characteristics shown in table 21.2.

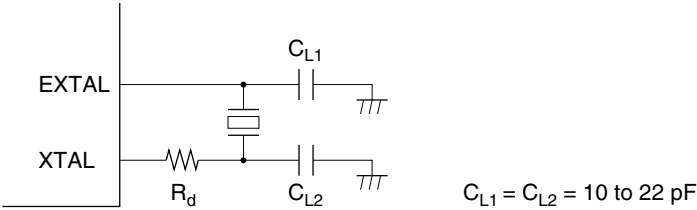

Figure 21.2 Connection of Crystal Oscillator (Example)

Table 21.1 Damping Resistance Value

Frequency (MHz)	8	12	16	20	25
$R_d (\Omega)$	200	0	0	0	0

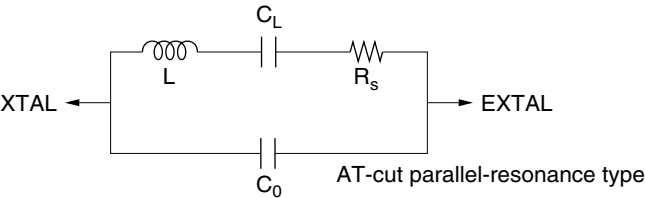

Figure 21.3 Crystal Oscillator Equivalent Circuit

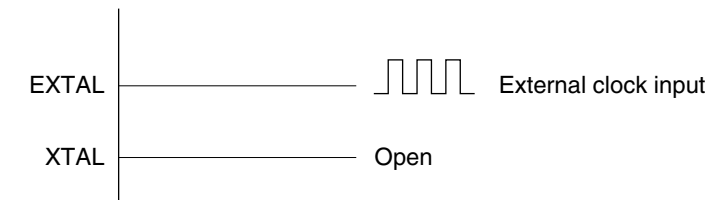

Table 21.2 Crystal Oscillator Characteristics

Frequency (MHz)	8	12	16	20	25
R_s max (Ω)	80	60	50	40	40
C_0 max (pF)	7	7	7	7	7

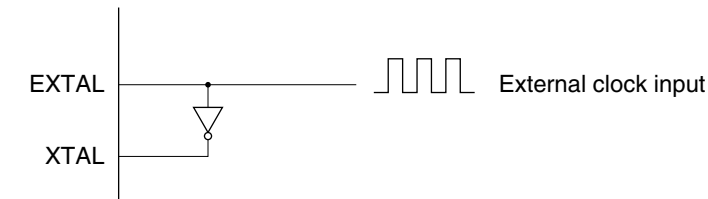

21.2.2 External Clock Input

An external clock signal can be input as shown in the examples in figure 21.4. If the XTAL pin is left open, make sure that parasitic capacitance is no more than 10 pF. When the counter clock is input to the XTAL pin, make sure that the external clock is held high in standby mode.

Table 21.3 shows the input conditions for the external clock. The frequency of an external clock to be input should be 8 MHz to 25 MHz.

(a) XTAL pin left open

(b) Counter clock input at XTAL pin

Figure 21.4 External Clock Input (Examples)

Table 21.3 External Clock Input Conditions

Item	Symbol	$V_{CC} = 3.0\text{ V}$ to 3.6 V		Unit	Test Conditions
		Min	Max		
External clock input low pulse width	t_{EXL}	15	—	ns	Figure 21.5
External clock input high pulse width	t_{EXH}	15	—	ns	
External clock rise time	t_{EXr}	—	5	ns	
External clock fall time	t_{EXf}	—	5	ns	
Clock low pulse width	t_{CL}	0.4	0.6	t_{cyc}	
Clock high pulse width	t_{CH}	0.4	0.6	t_{cyc}	

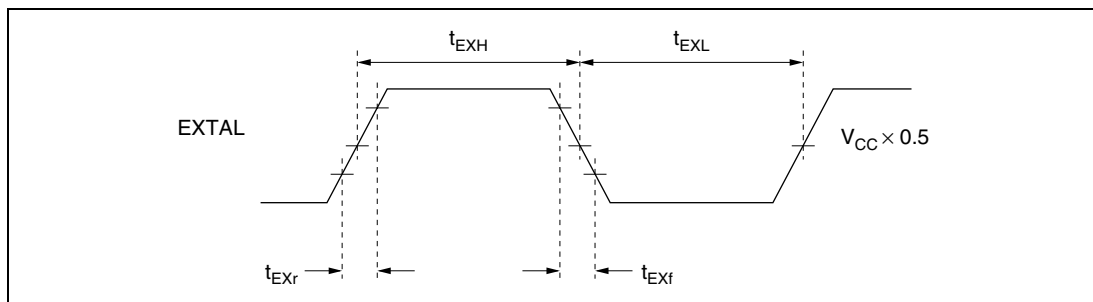

Figure 21.5 External Clock Input Timing

21.3 PLL Circuit

The PLL circuit has the function of multiplying the frequency of the clock from the oscillator by a factor of 1, 2, or 4. The multiplication factor is set with the STC1 and the STC0 bits in PLLCR. The phase of the rising edge of the internal clock is controlled so as to match that of the rising edge of the EXTAL pin.

When the multiplication factor of the PLL circuit is changed, the operation varies according to the setting of the STCS bit in SCKCR.

When $STCS = 0$, the setting becomes valid after a transition to software standby mode. The transition time count is performed in accordance with the setting of bits STS3 to STS0 in SBYCR. For details on SBYCR, refer to section 22.1.1, Standby Control Register (SBYCR).

1. The initial PLL circuit multiplication factor is 1.
2. A value is set in bits STS3 to STS0 to give the specified transition time.

3. The target value is set in bits STC1 and STC0, and a transition is made to software standby mode.
4. The clock pulse generator stops and the value set in STC1 and STC0 becomes valid.
5. Software standby mode is cleared, and a transition time is secured in accordance with the setting in STS3 to STS0.
6. After the set transition time has elapsed, this LSI resumes operation using the target multiplication factor.

When STCS = 1, this LSI operates using the new multiplication factor immediately after bits STC1 and STC0 are rewritten.

21.4 Frequency Divider

The frequency divider divides the PLL output clock to generate a 1/2 or 1/4 clock.

21.5 Usage Notes

21.5.1 Notes on Clock Pulse Generator

1. The following points should be noted since the frequency of ϕ changes according to the setting of SCKCR and PLLCR.
Select the clock division ratio that is within the operation guaranteed range of clock cycle time t_{cyc} shown in the AC timing of Electrical Characteristics. In other words, the range of ϕ must be specified from 8 MHz (min) to 33 MHz (max); outside of this range must be prevented.
2. All the on-chip peripheral modules operate on the ϕ . Therefore, note that the time processing of modules such as a timer and SCI differ before and after changing the clock division ratio. In addition, wait time for clearing software standby mode differs by changing the clock division ratio. See the description, Setting Oscillation Stabilization Time after Clearing Software Standby Mode in section 22.2.3, Software Standby Mode, for details.
3. Note that the frequency of ϕ will be changed when setting SCKCR or PLLCR while executing the external bus cycle with the write-data-buffer function.

21.5.2 Notes on Oscillator

Since various characteristics related to the oscillator are closely linked to the user's board design, thorough evaluation is necessary on the user's part, using the oscillator connection examples shown in this section as a guide. As the oscillator circuit ratings will depend on the floating capacitance of the oscillator and the mounting circuit, the ratings should be determined in consultation with the oscillator manufacturer. The design must ensure that a voltage exceeding the maximum rating is not applied to the oscillator pin.

21.5.3 Notes on Board Design

When using the crystal oscillator, place the crystal oscillator and its load capacitors as close as possible to the XTAL and EXTAL pins. Other signal lines should be routed away from the oscillator circuit to prevent induction from interfering with correct oscillation. See figure 21.6.

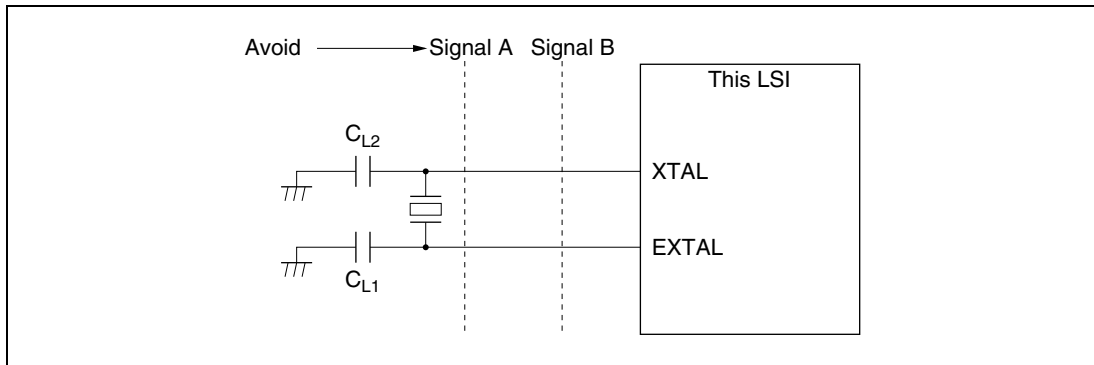

Figure 21.6 Note on Oscillator Board Design

Figure 21.7 shows the external circuitry recommended for the PLL circuit. Separate PLLVcc and PLLVss from the other Vcc and Vss lines at the board power supply source, and be sure to insert bypass capacitors CPB and CB close to the pins.

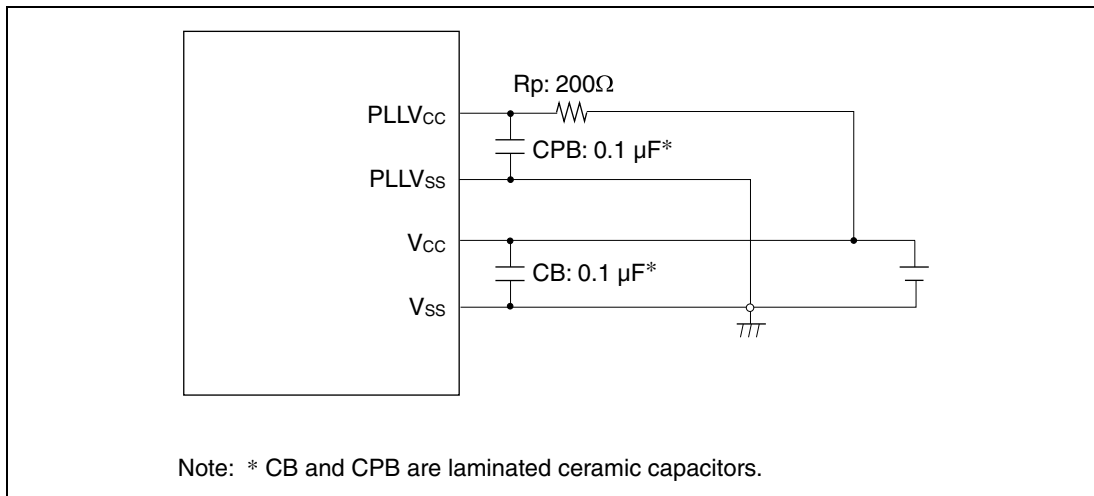

Figure 21.7 Recommended External Circuitry for PLL Circuit

Section 22 Power-Down Modes

In addition to the normal program execution state, this LSI has power-down modes in which operation of the CPU and oscillator is halted and power dissipation is reduced. Low-power operation can be achieved by individually controlling the CPU, on-chip peripheral modules, and so on.

This LSI's operating modes are high-speed mode and six power down modes:

- Clock division mode
- Sleep mode
- Module stop mode
- All module clock stop mode
- Software standby mode
- Hardware standby mode

Sleep mode is a CPU state, clock division mode is an on-chip peripheral function (including bus masters and the CPU) state, and module stop mode is an on-chip peripheral function (including bus masters other than the CPU) state. A combination of these modes can be set.

After a reset, this LSI is in high-speed mode.

Table 22.1 shows the internal states of this LSI in each mode. Figure 22.1 shows the mode transition diagram.

Table 22.1 Operating Modes and Internal States of the LSI

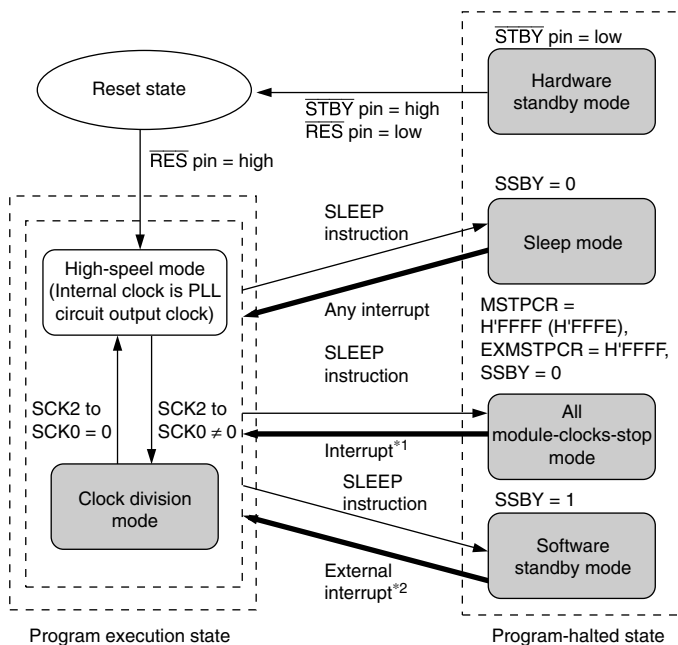

Operating State		High Speed Mode	Clock Division Mode	Sleep Mode	Module Stop Mode	All Module Clock Stop Mode	Software Standby Mode	Hardware Standby Mode
Clock pulse generator		Functions	Functions	Functions	Functions	Functions	Halted	Halted
CPU	Instruction execution	Functions	Functions	Halted	Functions	Halted	Halted	Halted
	Register			Retained			Retained	Undefined
External interrupts	NMI	Functions	Functions	Functions	Functions	Functions	Functions	Halted
	IRQ0 to 7							
Peripheral functions	WDT	Functions	Functions	Functions	Functions	Functions	Halted (Retained)	Halted (Reset)
	TMR	Functions	Functions	Functions	Halted (Retained)	Functions/ Halted (Retained)*	Halted (Retained)	Halted (Reset)
	DMAC* ²	Functions	Functions	Functions	Halted (Retained)	Halted (Retained)	Halted (Retained)	Halted (Reset)
	DTC	Functions	Functions	Functions	Halted (Retained)	Halted (Retained)	Halted (Retained)	Halted (Reset)
	TPU	Functions	Functions	Functions	Halted (Retained)	Halted (Retained)	Halted (Retained)	Halted (Reset)
	PPG* ²	Functions	Functions	Functions	Halted (Retained)	Halted (Retained)	Halted (Retained)	Halted (Reset)
	D/A	Functions	Functions	Functions	Halted (Retained)	Halted (Retained)	Halted (Retained)	Halted (Reset)

	SCI	Functions	Functions	Functions	Halted* ³ (Reset/ Retained)	Halted* ³ (Reset/ Retained)	Halted* ³ (Reset/ Retained)	Halted (Reset)
	IIC2	Functions	Functions	Functions	Halted* ⁴ (Reset/ Retained)	Halted* ⁴ (Reset/ Retained)	Halted* ⁴ (Reset/ Retained)	Halted (Reset)
	RAM	Functions	Functions	Functions	Functions	Functions	Retained	Retained
	I/O	Functions	Functions	Functions	Functions	Retained	Retained	High impedance

Notes: “Halted (Retained)” in the table means that internal register values are retained and internal operations are suspended.

“Halted (Reset)” in the table means that internal register values and internal states are initialized.

In module stop mode, only modules for which a stop setting has been made are halted (reset or retained).

- *1 The active or halted state can be selected by means of the MSTP0 bit in MSTPCR.
- *2 Not supported by the H8S/2366.
- *3 TDR, SSR, and RDR are halted (reset) and other registers are halted (retained).
- *4 BC2 to BC0 are halted (reset) and other registers are halted (retained).

Notes: *1 NMI, $\overline{\text{IRQ0}}$ to $\overline{\text{IRQ7}}$, 8-bit timer interrupts, watchdog timer interrupts.
(8-bit timer interrupts are valid when MSTP0 = 0.)

*2 NMI, $\overline{\text{IRQ0}}$ to $\overline{\text{IRQ7}}$
(IRQ0 to IRQ15 are valid when the corresponding bit in SSIER is 1.)

- When a transition is made between modes by means of an interrupt, the transition cannot be made on interrupt source generation alone. Ensure that interrupt handling is performed after accepting the interrupt request.
- From any state, a transition to hardware standby mode occurs when $\overline{\text{STBY}}$ is driven low.
- From any state except hardware standby mode, a transition to the reset state occurs when $\overline{\text{RES}}$ is driven low.

Figure 22.1 Mode Transitions

22.1 Register Descriptions

The registers relating to the power-down mode are shown below. For details on the system clock control register (SCKCR), refer to section 21.1.1, System Clock Control Register (SCKCR).

- System clock control register (SCKCR)
- Standby control register (SBYCR)
- Module stop control register H (MSTPCRH)
- Module stop control register L (MSTPCRL)
- Extension module stop control register H (EXMSTPCRH)
- Extension module stop control register L (EXMSTPCRL)

22.1.1 Standby Control Register (SBYCR)

SBYCR performs software standby mode control.

Bit	Bit Name	Initial Value	R/W	Description
7	SSBY	0	R/W	<p>Software Standby</p> <p>This bit specifies the transition mode after executing the SLEEP instruction</p> <p>0: Shifts to sleep mode after the SLEEP instruction is executed</p> <p>1: Shifts to software standby mode after the SLEEP instruction is executed</p> <p>This bit does not change when clearing the software standby mode by using external interrupts and shifting to normal operation. This bit should be written 0 when clearing.</p>
6	OPE	1	R/W	<p>Output Port Enable</p> <p>Specifies whether the output of the address bus and bus control signals ($\overline{CS0}$ to $\overline{CS7}$, \overline{AS}, \overline{RD}, \overline{HWR}, \overline{LWR}, $\overline{UCAS^*}$, $\overline{LCAS^*}$) is retained or set to the high-impedance state in software standby mode.</p> <p>0: In software standby mode, address bus and bus control signals are high-impedance</p> <p>1: In software standby mode, address bus and bus control signals retain output state</p>

Bit	Bit Name	Initial Value	R/W	Description
5	—	0	—	Reserved
4	—	0	—	These bits are always read as 0. The initial value should not be changed.
3	STS3	1	R/W	Standby Timer Select 3 to 0
2	STS2	1	R/W	<p>These bits select the time the MCU waits for the clock to stabilize when software standby mode is cleared by an external interrupt. With crystal oscillation, refer to table 22.2 and make a selection according to the operating frequency so that the standby time is at least the oscillation stabilization time. With an external clock, a PLL circuit stabilization time is necessary. Refer to table 22.2 to set the wait time. When DRAM* is used and self-refreshing in the software standby state is selected, note that the DRAM*'s tRAS (self-refresh RAS pulse width) specification must be satisfied.</p> <p>With the F-ZTAT version, a flash memory stabilization time must be provided.</p> <p>0000: Setting prohibited</p> <p>0001: Setting prohibited</p> <p>0010: Setting prohibited</p> <p>0011: Setting prohibited</p> <p>0100: Setting prohibited</p> <p>0101: Standby time = 64 states</p> <p>0110: Standby time = 512 states</p> <p>0111: Standby time = 1024 states</p> <p>1000: Standby time = 2048 states</p> <p>1001: Standby time = 4096 states</p> <p>1010: Standby time = 16384 states</p> <p>1011: Standby time = 32768 states</p> <p>1100: Standby time = 65536 states</p> <p>1101: Standby time = 131072 states</p> <p>1110: Standby time = 262144 states</p> <p>1111: Standby time = 524288 states</p>
1	STS1	1	R/W	
0	STS0	1	R/W	

Note: * Not supported by the H8S/2366.

22.1.2 Module Stop Control Registers H and L (MSTPCRH, MSTPCRL)

MSTPCR performs module stop mode control.

Setting a bit to 1, the corresponding module enters module stop mode, while clearing the bit to 0 clears the module stop mode.

- MSTPCRH

Bit	Bit Name	Initial Value	R/W	Module
15	ACSE	0	R/W	All-Module-Clocks-Stop Mode Enable Enables or disables all-module-clocks-stop mode, in which, when the CPU executes a SLEEP instruction after module stop mode has been set for all the on-chip peripheral functions controlled by MSTPCR or the on-chip peripheral functions except the TMR. 0: All-module-clocks-stop mode disabled 1: All-module-clocks-stop mode enabled
14	MSTP14	0	R/W	—
13	MSTP13	0	R/W	DMA controller (DMAC)*
12	MSTP12	0	R/W	Data transfer controller (DTC)
11	MSTP11	1	R/W	16-bit timer-pulse unit (TPU)
10	MSTP10	1	R/W	Programmable pulse generator (PPG)*
9	MSTP9	1	R/W	—
8	MSTP8	1	R/W	D/A converter (channels 2 and 3)

Note: * Not supported by the H8S/2366.

- MSTPCRL

Bit	Bit Name	Initial Value	R/W	Module
7	MSTP7	1	R/W	—
6	MSTP6	1	R/W	A/D converter
5	MSTP5	1	R/W	Serial communication interface 4 (SCI_4)
4	MSTP4	1	R/W	Serial communication interface 3 (SCI_3)
3	MSTP3	1	R/W	Serial communication interface 2 (SCI_2)
2	MSTP2	1	R/W	Serial communication interface 1 (SCI_1)
1	MSTP1	1	R/W	Serial communication interface 0 (SCI_0)
0	MSTP0	1	R/W	8-bit timer (TMR)

22.1.3 Extension Module Stop Control Registers H and L (EXMSTPCR_H, EXMSTPCR_L)

EXMSTPCR performs all-module-clocks-stop mode control with MSTPCR.

When entering all-module-clocks-stop mode, set EXMSTPCR to H'FFFF. Otherwise, set EXMSTPCR to H'FFFD.

- EXMSTPCR_H

Bit	Bit Name	Initial Value	R/W	Module
15 to 12	—	1	R/W	Reserved Read/write is enabled. 1 should be written in writing.
11	MSTP27	1	R/W	—
10	MSTP26	1	R/W	—
9	MSTP25	1	R/W	—
8	MSTP24	1	R/W	—

- EXMSTPCR_L

Bit	Bit Name	Initial Value	R/W	Module
7	MSTP23	1	R/W	—
6	MSTP22	1	R/W	—
5	MSTP21	1	R/W	—
4	MSTP20	1	R/W	I ² C bus interface 2_1 (IIC2_1)
3	MSTP19	1	R/W	I ² C bus interface 2_0 (IIC2_0)
2	MSTP18	1	R/W	—
1	MSTP17	0	R/W	—
0	MSTP16	1	R/W	—

22.2 Operation

22.2.1 Clock Division Mode

When bits SCK2 to SCK0 in SCKCR are set to a value from 001 to 101, a transition is made to clock division mode at the end of the bus cycle. In clock division mode, the CPU, bus masters, and on-chip peripheral functions all operate on the operating clock (1/2 or 1/4) specified by bits SCK2 to SCK0.

Clock division mode is cleared by clearing all of bits SCK2 to SCK0 to 0. A transition is made to high-speed mode at the end of the bus cycle, and clock division mode is cleared.

If a SLEEP instruction is executed while the SSBY bit in SBYCR is cleared to 0, the chip enters sleep mode. When sleep mode is cleared by an interrupt, clock division mode is restored.

If a SLEEP instruction is executed while the SSBY bit in SBYCR is set to 1, the chip enters software standby mode. When software standby mode is cleared by an external interrupt, clock division mode is restored.

When the $\overline{\text{RES}}$ pin is driven low, the reset state is entered and clock division mode is cleared. The same applies to a reset caused by watchdog timer overflow.

When the $\overline{\text{STBY}}$ pin is driven low, a transition is made to hardware standby mode.

22.2.2 Sleep Mode

Transition to Sleep Mode: When the SLEEP instruction is executed when the SSBY bit is 0 in SBYCR, the CPU enters the sleep mode. In sleep mode, CPU operation stops but the contents of the CPU's internal registers are retained. Other peripheral functions do not stop.

Exiting Sleep Mode: Sleep mode is exited by any interrupt, or signals at the $\overline{\text{RES}}$, or $\overline{\text{STBY}}$ pins.

- **Exiting Sleep Mode by Interrupts:**
When an interrupt occurs, sleep mode is exited and interrupt exception processing starts. Sleep mode is not exited if the interrupt is disabled, or interrupts other than NMI are masked by the CPU.
- **Exiting Sleep Mode by $\overline{\text{RES}}$ pin:**
Setting the $\overline{\text{RES}}$ pin level low selects the reset state. After the stipulated reset input duration, driving the $\overline{\text{RES}}$ pin high starts the CPU performing reset exception processing.
- **Exiting Sleep Mode by $\overline{\text{STBY}}$ Pin:**
When the $\overline{\text{STBY}}$ pin level is driven low, a transition is made to hardware standby mode.

22.2.3 Software Standby Mode

Transition to Software Standby Mode: If a SLEEP instruction is executed when the SSBY bit in SBYCR is set to 1, software standby mode is entered. In this mode, the CPU, on-chip peripheral functions, and oscillator all stop. However, the contents of the CPU's internal registers, RAM data, and the states of on-chip peripheral functions other than the SCI and A/D converter, and I/O ports, are retained. Whether the address bus and bus control signals are placed in the high-impedance state or retain the output state can be specified by the OPE bit in SBYCR.

In this mode the oscillator stops, and therefore power dissipation is significantly reduced.

Clearing Software Standby Mode: Software standby mode is cleared by an external interrupt (NMI pin, or pins $\overline{\text{IRQ0}}$ to $\overline{\text{IRQ7}}$), or by means of the $\overline{\text{RES}}$ pin or $\overline{\text{STBY}}$ pin. Setting the SSI bit in SSIER to 1 enables $\overline{\text{IRQ0}}$ to $\overline{\text{IRQ7}}$ to be used as software standby mode clearing sources.

Clearing with an Interrupt:

When an NMI or IRQ0 to IRQ7 interrupt request signal is input, clock oscillation starts, and after the elapse of the time set in bits STS3 to STS0 in SBYCR, stable clocks are supplied to the entire LSI, software standby mode is cleared, and interrupt exception handling is started.

When clearing software standby mode with an IRQ0 to IRQ7 interrupt, set the corresponding enable bit to 1 and ensure that no interrupt with a higher priority than interrupts IRQ0 to IRQ7 is generated. Software standby mode cannot be cleared if the interrupt has been masked on the CPU side or has been designated as a DTC activation source.

Clearing with the $\overline{\text{RES}}$ Pin:

When the $\overline{\text{RES}}$ pin is driven low, clock oscillation is started. At the same time as clock oscillation starts, clocks are supplied to the entire LSI. Note that the $\overline{\text{RES}}$ pin must be held low until clock oscillation stabilizes. When the $\overline{\text{RES}}$ pin goes high, the CPU begins reset exception handling.

Clearing with the $\overline{\text{STBY}}$ Pin:

When the $\overline{\text{STBY}}$ pin is driven low, a transition is made to hardware standby mode.

Setting Oscillation Stabilization Time after Clearing Software Standby Mode: Bits STS3 to STS0 in SBYCR should be set as described below.

Using a Crystal Oscillator:

Set bits STS3 to STS0 so that the standby time is more than the oscillation stabilization time.

Table 22.2 shows the standby times for operating frequencies and settings of bits STS3 to STS0.

Using an External Clock:

A PLL circuit stabilization time is necessary. Refer to table 22.2 to set the wait time.

Table 22.2 Oscillation Stabilization Time Settings

STS3	STS2	STS1	STS0	Standby Time	ϕ^* [MHz]						Unit
					33	25	20	13	10	8

			1								

 : Recommended time setting

Note: * ϕ is the frequency divider output.

Software Standby Mode Application Example: Figure 22.2 shows an example in which a transition is made to software standby mode at the falling edge on the NMI pin, and software standby mode is cleared at the rising edge on the NMI pin.

In this example, an NMI interrupt is accepted with the NMIEG bit in INTCR cleared to 0 (falling edge specification), then the NMIEG bit is set to 1 (rising edge specification), the SSBY bit is set to 1, and a SLEEP instruction is executed, causing a transition to software standby mode.

Software standby mode is then cleared at the rising edge on the NMI pin.

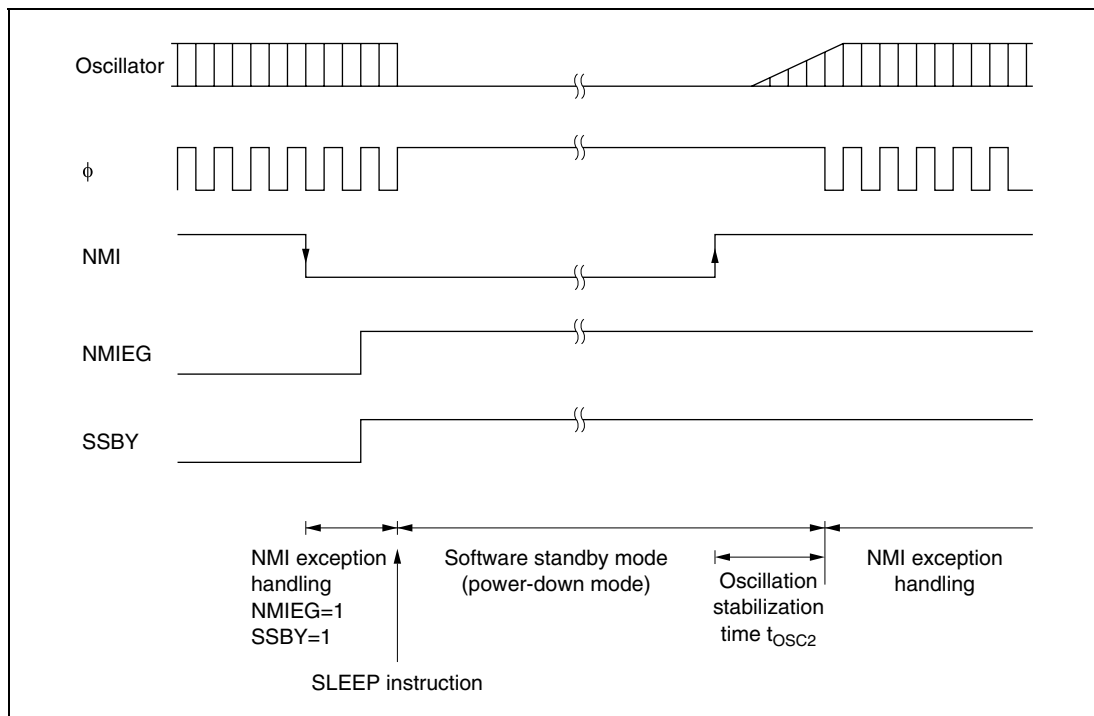

Figure 22.2 Software Standby Mode Application Example

22.2.4 Hardware Standby Mode

Transition to Hardware Standby Mode: When the \overline{STBY} pin is driven low, a transition is made to hardware standby mode from any mode.

In hardware standby mode, all functions enter the reset state and stop operation, resulting in a significant reduction in power dissipation. As long as the prescribed voltage is supplied, on-chip RAM data is retained. I/O ports are set to the high-impedance state.

In order to retain on-chip RAM data, the RAME bit in SYSCR should be cleared to 0 before driving the \overline{STBY} pin low. Do not change the state of the mode pins (MD2 to MD0) while this LSI is in hardware standby mode.

Clearing Hardware Standby Mode: Hardware standby mode is cleared by means of the $\overline{\text{STBY}}$ pin and the $\overline{\text{RES}}$ pin. When the $\overline{\text{STBY}}$ pin is driven high while the $\overline{\text{RES}}$ pin is low, the reset state is set and clock oscillation is started. Ensure that the $\overline{\text{RES}}$ pin is held low until the clock oscillator stabilizes (for details on the oscillation stabilization time, refer to table 22.2). When the $\overline{\text{RES}}$ pin is subsequently driven high, a transition is made to the program execution state via the reset exception handling state.

Hardware Standby Mode Timing: Figure 22.3 shows an example of hardware standby mode timing.

When the $\overline{\text{STBY}}$ pin is driven low after the $\overline{\text{RES}}$ pin has been driven low, a transition is made to hardware standby mode. Hardware standby mode is cleared by driving the $\overline{\text{STBY}}$ pin high, waiting for the oscillation stabilization time, then changing the $\overline{\text{RES}}$ pin from low to high.

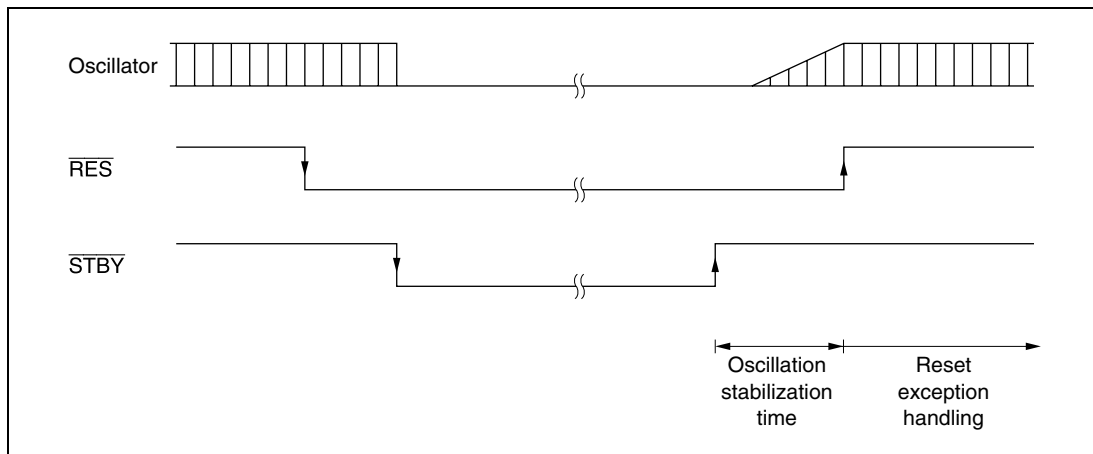

Figure 22.3 Hardware Standby Mode Timing

22.2.5 Module Stop Mode

Module stop mode can be set for individual on-chip peripheral modules.

When the corresponding MSTP bit in MSTPCR or EXMSTPCR is set to 1, module operation stops at the end of the bus cycle and a transition is made to module stop mode. The CPU continues operating independently.

When the corresponding MSTP bit is cleared to 0, module stop mode is cleared and the module starts operating at the end of the bus cycle. In module stop mode, the internal states of modules other than the SCI are retained.

After reset clearance, all modules other than the DMAC*, and DTC are in module stop mode.

The module registers which are set in module stop mode cannot be read or written to.

Note: * Not supported by the H8S/2366.

22.2.6 All-Module-Clocks-Stop Mode

When the ACSE bit in MSTPCR is set to 1 and module stop mode is set for all the on-chip peripheral functions controlled by MSTPCR or EXMSTPCR (MSTPCR = H'FFFF, EXMSTPCR = H'FFFF), or for all the on-chip peripheral functions except the 8-bit timer (MSTPCR = H'FFFE, EXMSTPCR = H'FFFF), executing a SLEEP instruction while the SSBY bit in SBYCR is cleared to 0 will cause all the on-chip peripheral functions (except the 8-bit timer and watchdog timer), the bus controller, and the I/O ports to stop operating, and a transition to be made to all-module-clocks-stop mode, at the end of the bus cycle.

Operation or halting of the 8-bit timer can be selected by means of the MSTP0 bit.

All-module-clocks-stop mode is cleared by an external interrupt (NMI, $\overline{\text{IRQ0}}$ to $\overline{\text{IRQ7}}$ pins), $\overline{\text{RES}}$ pin input, or an internal interrupt (8-bit timer, watchdog timer), and the CPU returns to the normal program execution state via the exception handling state. All-module-clocks-stop mode is not cleared if interrupts are disabled, if interrupts other than NMI are masked by the CPU, or if the relevant interrupt is designated as a DTC activation source.

When the $\overline{\text{STBY}}$ pin is driven low, a transition is made to hardware standby mode.

22.3 ϕ Clock Output Control

Output of the ϕ clock can be controlled by means of the PSTOP bit in SCKCR, and DDR for the corresponding port. When the PSTOP bit is set to 1, the ϕ clock stops at the end of the bus cycle, and ϕ output goes high. ϕ clock output is enabled when the PSTOP bit is cleared to 0. When DDR for the corresponding port is cleared to 0, ϕ clock output is disabled and input port mode is set. Table 22.3 shows the state of the ϕ pin in each processing state.

Table 22.3 ϕ Pin State in Each Processing State

Register Setting						
DDR	PSTOP	Normal operating state	Sleep mode	Software standby mode	Hardware standby mode	All-module-clocks-stop mode
0	X	High impedance	High impedance	High impedance	High impedance	High impedance
1	0	ϕ output	ϕ output	Fixed high	High impedance	ϕ output
1	1	Fixed high	Fixed high	Fixed high	High impedance	Fixed high

22.4 Usage Notes

22.4.1 I/O Port Status

In software standby mode, I/O port states are retained. Therefore, there is no reduction in current dissipation for the output current when a high-level signal is output.

22.4.2 Current Dissipation during Oscillation Stabilization Standby Period

Current dissipation increases during the oscillation stabilization standby period.

22.4.3 DMAC/DTC Module Stop

Depending on the operating status of the DMAC or DTC, the MSTP14 to MSTP13 and may not be set to 1. Setting of the DMAC or DTC module stop mode should be carried out only when the respective module is not activated.

For details, refer to section 7, DMA Controller (DMAC), and section 8, Data Transfer Controller (DTC).

Note: Not supported by the H8S/2366.

22.4.4 On-Chip Peripheral Module Interrupts

Relevant interrupt operations cannot be performed in module stop mode. Consequently, if module stop mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DMAC or DTC activation source.

Interrupts should therefore be disabled before entering module stop mode.

Note: Not supported by the H8S/2366.

22.4.5 Writing to MSTPCR, EXMSTPCR

MSTPCR and EXMSTPCR should only be written to by the CPU.

22.4.6 Notes on Clock Division Mode

The following points should be noted in clock division mode.

- Select the clock division ratio specified by the SCK2 to SCK0 bits so that the frequency of ϕ is within the operation guaranteed range of clock cycle time (t_{cyc}) shown in the Electrical Characteristics. In other words, the range of ϕ must be specified to 8 MHz (min.); outside of this range ($\phi < 8$ MHz) must be prevented.
- All the on-chip peripheral modules operate on the ϕ . Therefore, note the time processing of modules such as a timer and SCI differ before and after changing the clock division ratio. In addition, wait time for clearing software standby mode differs by changing the clock division ratio.
- Note that the frequency of ϕ will be changed by changing the clock division ratio.

Section 23 List of Registers

The address list gives information on the on-chip I/O register addresses, how the register bits are configured, and the register states in each operating mode. The information is given as shown below.

1. Register addresses (address order)
 - Registers are listed from the lower allocation addresses.
 - Registers are classified by functional modules.
 - The access size is indicated.
2. Register bits
 - Bit configurations of the registers are described in the same order as the register addresses.
 - Reserved bits are indicated by — in the bit name column.
 - No entry in the bit-name column indicates that the whole register is allocated as a counter or for holding data.
 - For the registers of 16 or 32 bits, the MSB is described first.
3. Register states in each operating mode
 - Register states are described in the same order as the register addresses.
 - The register states described here are for the basic operating modes. If there is a specific reset for an on-chip peripheral module, refer to the section on that on-chip peripheral module.

23.1 Register Addresses (Address Order)

The data bus width indicates the numbers of bits by which the register is accessed.

The number of access states indicates the number of states based on the specified reference clock.

Register Name	Abbrevia- tion	Bit No.	Address	Module	Data Width	Access States
DTC mode register A	MRA	8	H'BC00	DTC	16/32	2
DTC source address register	SAR	24	to	DTC	16/32	2

Notes: *1 If the pulse output group 2 and pulse output group 3 output triggers are the same according to the PCR setting, the NDRH address will be H'FF4C, and if different, the address of NDRH for group 2 will be H'FF4E, and that for group 3 will be H'FF4C. Similarly, if the pulse output group 0 and pulse output group 1 output triggers are the same according to the PCR setting, the NDRL address will be H'FF4D, and if different, the address of NDRL for group 0 will be H'FF4F, and that for group 1 will be H'FF4D.

*2 For writing, refer to section 13.6.1, Notes on Register Access.

*3 Not supported by the H8S/2366.

23.2 Register Bits

Register bit names of the on-chip peripheral modules are described below.

Each line covers eight bits, and 16- or 32-bit registers are shown as 2 or 4 lines.

Register Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Module

- Notes:
- *1 Loaded in on-chip RAM. The bus width is 32 bits when the DTC accesses this area as register information, and 16 bits otherwise.
 - *2 For short address mode
 - *3 For full address mode
 - *4 For normal mode
 - *5 For smart card interface mode
 - *6 If the pulse output group 2 and pulse output group 3 output triggers are the same according to the PCR setting, the NDRH address will be H'FF4C, and if different, the address of NDRH for group 2 will be H'FF4E, and that for group 3 will be H'FF4C. Similarly, if the pulse output group 0 and pulse output group 1 output triggers are the same according to the PCR setting, the NDRL address will be H'FF4D, and if different, the address of NDRL for group 0 will be H'FF4F, and that for group 1 will be H'FF4D.
 - *7 Not supported by the H8S/2366.

24.1 Electrical Characteristics of Masked ROM and ROMless Versions

24.1.1 Absolute Maximum Ratings

Table 24.1 lists the absolute maximum ratings.

Table 24.1 Absolute Maximum Ratings

Item	Symbol	Value	Unit
Power supply voltage	V_{CC} $PLL V_{CC}$	−0.3 to +4.0	V
Input voltage (except ports 4, 9)	V_{in}	−0.3 to $V_{CC} + 0.3$	V
Input voltage (ports 4, 9)	V_{in}	−0.3 to $AV_{CC} + 0.3$	V
Reference power supply voltage	V_{ref}	−0.3 to $AV_{CC} + 0.3$	V
Analog power supply voltage	AV_{CC}	−0.3 to +4.0	V
Analog input voltage	V_{AN}	−0.3 to $AV_{CC} + 0.3$	V
Operating temperature	T_{opr}	Regular specifications: −20 to +75	°C
		Wide-range specifications: −40 to +85	°C
Storage temperature	T_{stg}	−55 to +125	°C

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

24.1.2 DC Characteristics

Table 24.2 DC Characteristics (1)

Conditions: $V_{CC} = 3.0\text{ V to }3.6\text{ V}$, $AV_{CC} = 3.0\text{ V to }3.6\text{ V}$, $V_{ref} = 3.0\text{ V to }AV_{CC}$,
 $V_{SS} = AV_{SS} = 0\text{ V}^{*1}$, $T_a = -20^{\circ}\text{C to }+75^{\circ}\text{C}$ (regular specifications),
 $T_a = -40^{\circ}\text{C to }+85^{\circ}\text{C}$ (wide-range specifications)

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Schmitt trigger input voltage	Ports 1, 2, and 4 ^{*2} , P50 to P53 ^{*2} , PA4 to PA7 ^{*2}	VT^-	$V_{CC} \times 0.2$	—	—	V	
		VT^+	—	—	$V_{CC} \times 0.7$	V	
		$VT^+ - VT^-$	$V_{CC} \times 0.07$	—	—	V	
Input high voltage	STBY, MD2 to MD0	V_{IH}	$V_{CC} \times 0.9$	—	$V_{CC} + 0.3$	V	
	RES, NMI, EMLE		$V_{CC} \times 0.9$	—	$V_{CC} + 0.3$	V	
	EXTAL		$V_{CC} \times 0.7$	—	$V_{CC} + 0.3$	V	
	Port 3, P50 to P53 ^{*3} , port 8 ^{*3} , ports A to G ^{*3}		2.2V	—	$V_{CC} + 0.3$	V	
	Ports 4 and 9		2.2V	—	$V_{CC} + 0.3$	V	
Input low voltage	RES, STBY, MD2 to MD0, EMLE	V_{IL}	-0.3	—	$V_{CC} \times 0.1$	V	
	NMI, EXTAL		-0.3	—	$V_{CC} \times 0.2$	V	
	Ports 3 to 5, 8, 9, A to G ^{*3}		-0.3	—	$V_{CC} \times 0.2$	V	
Output high voltage	All output pins	V_{OH}	$V_{CC} - 0.5$	—	—	V	$I_{OH} = -200\text{ }\mu\text{A}$
			$V_{CC} - 1.0$	—	—	V	$I_{OH} = -1\text{ mA}$
Output low voltage	All output pins	V_{OL}	—	—	0.4	V	$I_{OL} = 1.6\text{ mA}$

Notes: *1 When the A/D and D/A converters are not used, do not leave the AV_{CC} , V_{ref} , and AV_{SS} pins open. Connect the AV_{CC} and V_{ref} pins to V_{CC} , and the AV_{SS} pin to V_{SS} .

*2 When used as $\overline{IRQ0}$ to $\overline{IRQ7}$.

*3 When used as other than $\overline{IRQ0}$ to $\overline{IRQ7}$.

Table 24.3 DC Characteristics (2)

Conditions: $V_{CC} = 3.0\text{ V to }3.6\text{ V}$, $AV_{CC} = 3.0\text{ V to }3.6\text{ V}$, $V_{ref} = 3.0\text{ V to }AV_{CC}$,
 $V_{SS} = AV_{SS} = 0\text{ V}^{*1}$, $T_a = -20^{\circ}\text{C to }+75^{\circ}\text{C}$ (regular specifications),
 $T_a = -40^{\circ}\text{C to }+85^{\circ}\text{C}$ (wide-range specifications)

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Input leakage current	$\overline{\text{RES}}$	$ I_{in} $	—	—	10.0	μA	$V_{in} = 0.5\text{ to }V_{CC} - 0.5\text{ V}$
	$\overline{\text{STBY}}$, NMI, MD2 to MD0		—	—	1.0	μA	
	Ports 4 and 9		—	—	1.0	μA	$V_{in} = 0.5\text{ to }AV_{CC} - 0.5\text{ V}$
Three-state leakage current (off state)	Ports 1 to 3, P50 to P53, ports 8, A to G	$ I_{TSI} $	—	—	1.0	μA	$V_{in} = 0.5\text{ to }V_{CC} - 0.5\text{ V}$
Input pull-up MOS current	Ports A to E	$-I_p$	10	—	300	μA	$V_{CC} = 3.0\text{ to }3.6\text{ V}$ $V_{in} = 0\text{ V}$
Input capacitance	$\overline{\text{RES}}$	C_{in}	—	—	30	pF	$V_{in} = 0\text{ V}$
	NMI		—	—	30	pF	$f = 1\text{ MHz}$
	All input pins except RES and NMI		—	—	15	pF	$T_a = 25^{\circ}\text{C}$
Current dissipation ^{*2}	Normal operation	I_{CC}^{*4}	—	75 (3.3 V)	115	mA	$f = 33\text{ MHz}$
	Sleep mode		—	55 (3.3 V)	95	mA	$f = 33\text{ MHz}$
	Standby mode ^{*3}		—	0.01	10	μA	$T_a \leq 50^{\circ}\text{C}$
			—	—	80	μA	$50^{\circ}\text{C} < T_a$
Analog power supply current	During A/D and D/A conversion	AI_{CC}	—	0.3 (3.0 V)	2.0	mA	
	Idle		—	0.01	5.0	μA	

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Reference power supply current	During A/D and D/A conversion	AI_{CC}	—	2.0 (3.0 V)	3.5	mA	
	Idle		—	0.01	5.0	μA	
RAM standby voltage		V_{RAM}	2.0	—	—	V	

Notes: *1 When the A/D and D/A converters are not used, do not leave the AV_{CC} , V_{ref} , and AV_{SS} pins open. Connect the AV_{CC} and V_{ref} pins to V_{CC} , and the AV_{SS} pin to V_{SS} .

*2 Current dissipation values are for $V_{IHmin} = V_{CC} - 0.2$ V and $V_{ILmax} = 0.2$ V with all output pins unloaded and all MOS input pull-ups in the off state.

*3 The values are for $V_{RAM} \leq V_{CC} < 3.0$ V, $V_{IHmin} = V_{CC} \times 0.9$, and $V_{ILmax} = 0.3$ V.

*4 I_{CC} depends on V_{CC} and f as follows:
 $I_{CCmax} = 1.0$ (mA) + 0.95 (mA/(MHz \times V)) $\times V_{CC} \times f$ (normal operation)
 $I_{CCmax} = 1.0$ (mA) + 0.8 (mA/(MHz \times V)) $\times V_{CC} \times f$ (sleep mode)

Table 24.4 Permissible Output Currents

Conditions: $V_{CC} = 3.0$ V to 3.6 V, $AV_{CC} = 3.0$ V to 3.6 V, $V_{ref} = 3.0$ V to AV_{CC} ,
 $V_{SS} = AV_{SS} = 0$ V*, $T_a = -20^\circ\text{C}$ to $+75^\circ\text{C}$ (regular specifications),
 $T_a = -40^\circ\text{C}$ to $+85^\circ\text{C}$ (wide-range specifications)

Item		Symbol	Min	Typ	Max	Unit
Permissible output low current (per pin)	All output pins	I_{OL}	—	—	2.0	mA
Permissible output low current (total)	Total of all output pins	ΣI_{OL}	—	—	80	mA
Permissible output high current (per pin)	All output pins	$-I_{OH}$	—	—	2.0	mA
Permissible output high current (total)	Total of all output pins	$\Sigma -I_{OH}$	—	—	40	mA

Caution: To protect the LSI's reliability, do not exceed the output current values in table 24.4.

Note: * When the A/D and D/A converters are not used, do not leave the AV_{CC} , V_{ref} , and AV_{SS} pins open. Connect the AV_{CC} and V_{ref} pins to V_{CC} , and the AV_{SS} pin to V_{SS} .

Conversion time	—	—	10	μs	20 pF capacitive load
Absolute accuracy	—	± 2.0	± 3.0	LSB	2 M Ω resistive load
	—	—	± 2.0	LSB	4 M Ω resistive load

24.2 Electrical Characteristics of F-ZTAT Version

24.2.1 Absolute Maximum Ratings

Table 24.13 lists the absolute maximum ratings.

Table 24.13 Absolute Maximum Ratings

Item	Symbol	Value	Unit
Power supply voltage	V_{CC} $PLL V_{CC}$	−0.3 to +4.0	V
Input voltage (except ports 4, 9)	V_{in}	−0.3 to $V_{CC} + 0.3$	V
Input voltage (ports 4, 9)	V_{in}	−0.3 to $AV_{CC} + 0.3$	V
Reference power supply voltage	V_{ref}	−0.3 to $AV_{CC} + 0.3$	V
Analog power supply voltage	AV_{CC}	−0.3 to +4.0	V
Analog input voltage	V_{AN}	−0.3 to $AV_{CC} + 0.3$	V
Operating temperature	T_{opr}	Regular specifications: −20 to +75*	°C
		Wide-range specifications: −40 to +85*	°C
Storage temperature	T_{stg}	−55 to +125	°C

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Note: * F-ZTAT version:

Ranges of operating temperature when flash memory is programmed/erased:

Regular specifications: 0 to +75°C

Wide-range specifications: 0 to +85°C

24.2.2 DC Characteristics

Table 24.14 DC Characteristics (1)

Conditions: $V_{CC} = 3.0\text{ V to }3.6\text{ V}$, $AV_{CC} = 3.0\text{ V to }3.6\text{ V}$, $V_{ref} = 3.0\text{ V to }AV_{CC}$,
 $V_{SS} = AV_{SS} = 0\text{ V}^{*1}$, $T_a = -20^{\circ}\text{C to }+75^{\circ}\text{C}$ (regular specifications),
 $T_a = -40^{\circ}\text{C to }+85^{\circ}\text{C}$ (wide-range specifications)

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Schmitt trigger input voltage	Ports 1, 2, and 4 ^{*2} , P50 to P53 ^{*2} , PA4 to PA7 ^{*2}	VT^-	$V_{CC} \times 0.2$	—	—	V	
		VT^+	—	—	$V_{CC} \times 0.7$	V	
		$VT^+ - VT^-$	$V_{CC} \times 0.07$	—	—	V	
Input high voltage	STBY, MD2 to MD0	V_{IH}	$V_{CC} \times 0.9$	—	$V_{CC} + 0.3$	V	
	RES, NMI, EMLE		$V_{CC} \times 0.9$	—	$V_{CC} + 0.3$	V	
	EXTAL		$V_{CC} \times 0.7$	—	$V_{CC} + 0.3$	V	
	Port 3, P50 to P53 ^{*3} , port 8 ^{*3} , ports A to G ^{*3}		$V_{CC} \times 0.7$	—	$V_{CC} + 0.3$	V	
	Ports 4 and 9		$AV_{CC} \times 0.7$	—	$AV_{CC} + 0.3$	V	
Input low voltage	RES, STBY, MD2 to MD0, EMLE	V_{IL}	-0.3	—	$V_{CC} \times 0.1$	V	
	NMI, EXTAL		-0.3	—	$V_{CC} \times 0.2$	V	
	Ports 3 to 5, 8, 9, A to G ^{*3}		-0.3	—	$V_{CC} \times 0.2$	V	
Output high voltage	All output pins	V_{OH}	$V_{CC} - 0.5$	—	—	V	$I_{OH} = -200\text{ }\mu\text{A}$
			$V_{CC} - 1.0$	—	—	V	$I_{OH} = -1\text{ mA}$
Output low voltage	All output pins	V_{OL}	—	—	0.4	V	$I_{OL} = 1.6\text{ mA}$

Notes: *1 When the A/D and D/A converters are not used, do not leave the AV_{CC} , V_{ref} , and AV_{SS} pins open. Connect the AV_{CC} and V_{ref} pins to V_{CC} , and the AV_{SS} pin to V_{SS} .

*2 When used as $\overline{IRQ0}$ to $\overline{IRQ7}$.

*3 When used as other than $\overline{IRQ0}$ to $\overline{IRQ7}$.

Table 24.15 DC Characteristics (2)

Conditions: $V_{CC} = 3.0\text{ V to }3.6\text{ V}$, $AV_{CC} = 3.0\text{ V to }3.6\text{ V}$, $V_{ref} = 3.0\text{ V to }AV_{CC}$,
 $V_{SS} = AV_{SS} = 0\text{ V}^{*1}$, $T_a = -20^\circ\text{C to }+75^\circ\text{C}$ (regular specifications),
 $T_a = -40^\circ\text{C to }+85^\circ\text{C}$ (wide-range specifications)

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Input leakage current	$\overline{\text{RES}}$	$ I_{in} $	—	—	10.0	μA	$V_{in} = 0.5\text{ to }V_{CC} - 0.5\text{ V}$
	$\overline{\text{STBY}}$, NMI, MD2 to MD0		—	—	1.0	μA	
	Ports 4 and 9		—	—	1.0	μA	$V_{in} = 0.5\text{ to }AV_{CC} - 0.5\text{ V}$
Three-state leakage current (off state)	Ports 1 to 3, P50 to P53, ports 8, A to G	$ I_{TSI} $	—	—	1.0	μA	$V_{in} = 0.5\text{ to }V_{CC} - 0.5\text{ V}$
Input pull-up MOS current	Ports A to E	$-I_p$	10	—	300	μA	$V_{CC} = 3.0\text{ to }3.6\text{ V}$ $V_{in} = 0\text{ V}$
Input capacitance	$\overline{\text{RES}}$	C_{in}	—	—	30	pF	$V_{in} = 0\text{ V}$
	NMI		—	—	30	pF	$f = 1\text{ MHz}$
	All input pins except RES and NMI		—	—	15	pF	$T_a = 25^\circ\text{C}$
Current dissipation ^{*2}	Normal operation	I_{CC}^{*4}	—	75 (3.3 V)	115	mA	$f = 33\text{ MHz}$
	Sleep mode		—	55 (3.3 V)	95	mA	$f = 33\text{ MHz}$
	Standby mode ^{*3}		—	0.01	10	μA	$T_a \leq 50^\circ\text{C}$
			—	—	80	μA	$50^\circ\text{C} < T_a$
Analog power supply current	During A/D and D/A conversion	AI_{CC}	—	0.3 (3.0 V)	2.0	mA	
	Idle		—	0.01	5.0	μA	

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Reference power supply current	During A/D and D/A conversion	AI_{CC}	—	2.0 (3.0 V)	3.5	mA	
	Idle		—	0.01	0.5	μA	
RAM standby voltage		V_{RAM}	2.0	—	—	V	

Notes: *1 When the A/D and D/A converters are not used, do not leave the AV_{CC} , V_{ref} , and AV_{SS} pins open. Connect the AV_{CC} and V_{ref} pins to V_{CC} , and the AV_{SS} pin to V_{SS} .

*2 Current dissipation values are for $V_{IHmin} = V_{CC} - 0.2$ V and $V_{ILmax} = 0.2$ V with all output pins unloaded and all MOS input pull-ups in the off state.

*3 The values are for $V_{RAM} \leq V_{CC} < 3.0$ V, $V_{IHmin} = V_{CC} \times 0.9$, and $V_{ILmax} = 0.3$ V.

*4 I_{CC} depends on V_{CC} and f as follows:
 $I_{CCmax} = 1.0$ (mA) + 0.95 (mA/(MHz \times V)) $\times V_{CC} \times f$ (normal operation)
 $I_{CCmax} = 1.0$ (mA) + 0.8 (mA/(MHz \times V)) $\times V_{CC} \times f$ (sleep mode)

Table 24.16 Permissible Output Currents

Conditions: $V_{CC} = 3.0$ V to 3.6 V, $AV_{CC} = 3.0$ V to 3.6 V, $V_{ref} = 3.0$ V to AV_{CC} ,
 $V_{SS} = AV_{SS} = 0$ V*, $T_a = -20^\circ\text{C}$ to $+75^\circ\text{C}$ (regular specifications),
 $T_a = -40^\circ\text{C}$ to $+85^\circ\text{C}$ (wide-range specifications)

Item		Symbol	Min	Typ	Max	Unit
Permissible output low current (per pin)	All output pins	I_{OL}	—	—	2.0	mA
Permissible output low current (total)	Total of all output pins	ΣI_{OL}	—	—	80	mA
Permissible output high current (per pin)	All output pins	$-I_{OH}$	—	—	2.0	mA
Permissible output high current (total)	Total of all output pins	$\Sigma -I_{OH}$	—	—	40	mA

Caution: To protect the LSI's reliability, do not exceed the output current values in table 24.16.

Note: * When the A/D and D/A converters are not used, do not leave the AV_{CC} , V_{ref} , and AV_{SS} pins open. Connect the AV_{CC} and V_{ref} pins to V_{CC} , and the AV_{SS} pin to V_{SS} .

(1) Clock Timing

Table 24.17 Clock Timing

Conditions: $V_{CC} = 3.0\text{ V to }3.6\text{ V}$, $AV_{CC} = 3.0\text{ V to }3.6\text{ V}$, $V_{ref} = 3.0\text{ V to }AV_{CC}$, $V_{SS} = AV_{SS} = 0\text{ V}$,
 $\phi = 8\text{ MHz to }33\text{ MHz}$, $T_a = -20^\circ\text{C to }+75^\circ\text{C}$ (regular specifications),

	Wait time after PV bit clearing* ¹	η	2	—	—	μs
	Wait time after SWE bit clearing* ¹	θ	100	—	—	μs
Maximum number of writes* ¹ * ⁴	N	—	—	1000* ⁵	Times	

Item		Symbol	Min	Typ	Max	Unit	Test Conditions
Erasing	Wait time after SWE bit setting* ¹	x	1	—	—	μs	Erase time wait
	Wait time after ESU bit setting* ¹	y	100	—	—	μs	
	Wait time after E bit setting* ¹ * ⁶	z	—	—	10	μs	
	Wait time after E bit clearing* ¹	α	10	—	—	μs	
	Wait time after ESU bit clearing* ¹	β	10	—	—	μs	
	Wait time after EV bit setting* ¹	γ	20	—	—	μs	
	Wait time after H'FF dummy write* ¹	ε	2	—	—	μs	
	Wait time after EV bit clearing* ¹	η	4	—	—	μs	
	Wait time after SWE bit clearing* ¹	θ	100	—	—	μs	
	Maximum number of erases* ¹ * ⁶	N	—	—	100	Times	

Notes: *1 Follow the program/erase algorithms when making the time settings.

*2 Programming time per 128 bytes. (Indicates the total time during which the P bit is set in flash memory control register 1 (FLMCR1). Does not include the program-verify time.)

*3 Time to erase one block. (Indicates the time during which the E bit is set in FLMCR1. Does not include the erase-verify time.)

*4 Maximum programming time

$$t_P(\max) = \sum_{i=1}^N \text{wait time after P bit setting (z)}$$

*5 The maximum number of writes (N) should be set as shown below according to the actual set value of (z) so as not to exceed the maximum programming time ($t_P(\max)$). The wait time after P bit setting (z) should be changed as follows according to the number of writes (n).

Number of writes (n)

$$1 \leq n \leq 6 \quad z = 30 \mu s$$

$$7 \leq n \leq 1000 \quad z = 200 \mu s$$

(Additional programming)

Number of writes (n)

$$1 \leq n \leq 6 \quad z = 10 \mu s$$

*6 For the maximum erase time ($t_E(\max)$), the following relationship applies between the wait time after E bit setting (z) and the maximum number of erases (N):

$$t_E(\max) = \text{Wait time after E bit setting (z)} \times \text{maximum number of erases (N)}$$

24.4 Usage Note

The F-ZTAT and masked ROM versions both satisfy the electrical characteristics shown in this manual, but actual electrical characteristic values, operating margins, noise margins, and other properties may vary due to differences in manufacturing process, on-chip ROM, layout patterns, and so on.

When system evaluation testing is carried out using the F-ZTAT version, the same evaluation testing should also be conducted for the masked ROM version when changing over to that version.

Appendix

A. I/O Port States in Each Pin State

Port Name	MCU Operating Mode	Reset	Hardware Standby Mode	Software Standby Mode	Bus Release State	Program Execution State Sleep Mode

B. Product Lineup

Product		Type Name	Model Marking	Package (Code)
H8S/2367	F-ZTAT version	HD64F2367	HD64F2367	120-pin TFP (TFP-120, TFP-120V*)
H8S/2366	F-ZTAT version	HD64F2366	HD64F2366	
H8S/2365	Masked ROM version	HD6432365	HD6432365	128-pin QFP (FP-128B, FP-128BV*)
H8S/2363	ROMless version	HD6412363	HD6412363	

*: Pb free version

Note: The above products include those under development or being planned. For the status of each product, contact a Renesas sales office. When using the optional functions for the F-ZTAT version, which has the common type name, contact a Renesas sales office.

C. Package Dimensions

For package dimensions, dimensions described in Renesas Technology Packages have priority.

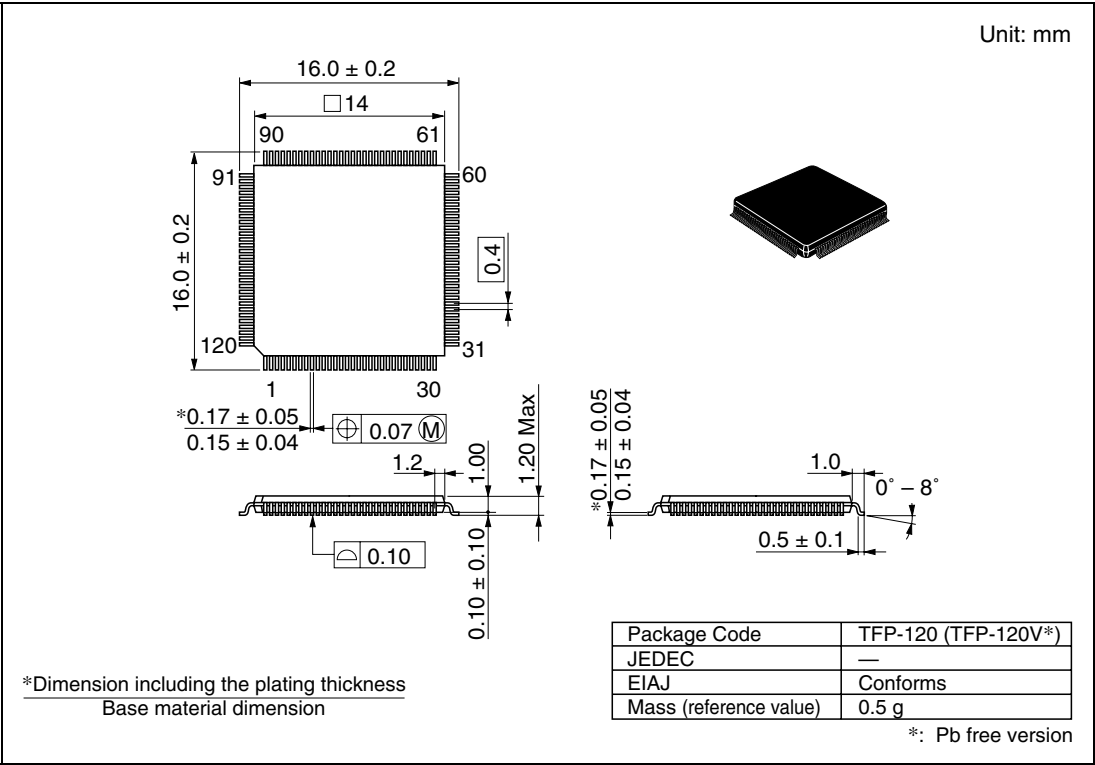

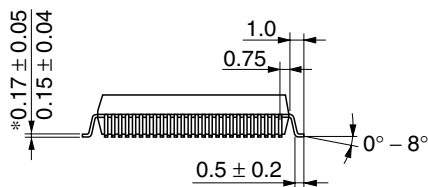

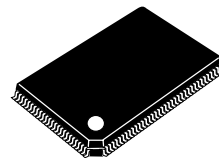

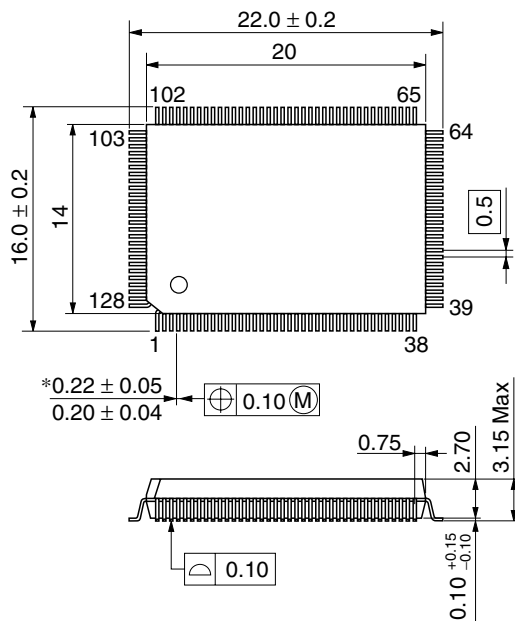

Figure C.1 Package Dimensions (TFP-120)

Package Code	FP-128B (FP-128BV*)
JEDEC	—
EIAJ	Conforms
Mass (reference value)	1.7 g

*: Pb free version

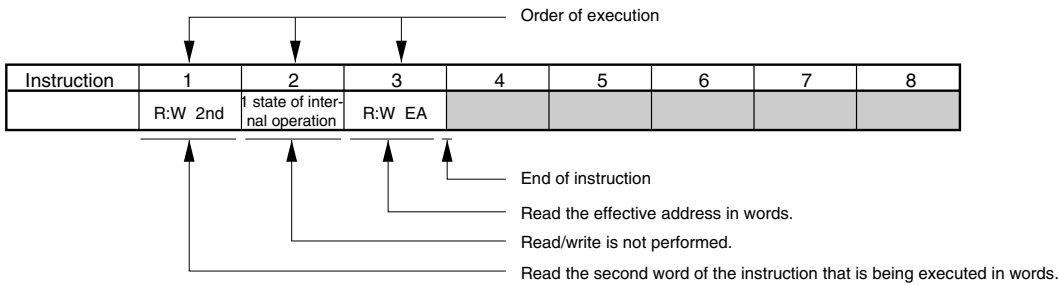

*Dimension including the plating thickness
Base material dimension

Figure C.2 Package Dimensions (FP-128B)

D. Bus State during Execution of Instructions

Table D.1 shows the execution state of each instruction in this LSI.

[Explanation of Table Contents]

[Legend]

R:B	Reading in bytes
R:W	Reading in words
W:B	Writing in bytes
W:W	Writing in words
:M	Bus right cannot be handed over immediately after this cycle
2nd	Address of second word (3rd and 4th bytes)
3rd	Address of third word (5th and 6th bytes)
4th	Address of fourth word (7th and 8th bytes)
5th	Address of fifth word (9th and 10th bytes)
NEXT	Start address of instruction immediately following the instruction being executed
EA	Effective address
VEC	Vector address

Figure D.1 shows the timing of the address bus, \overline{RD} , \overline{HWR} , and \overline{LWR} during execution of the sample instruction above (example in "Explanation of Table Contents") with an 8-bit bus, 3-state access, and no wait.

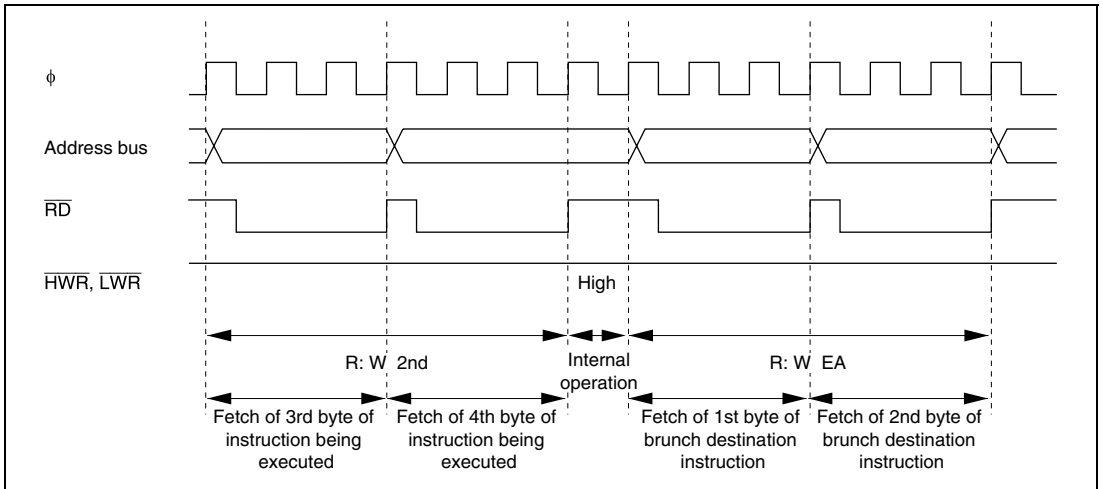

Figure D.1 Timing of Address Bus, \overline{RD} , \overline{HWR} , and \overline{LWR} (8-bit bus, 3-state access, no wait)

Interrupt Advanced exception R:W * ⁵ handling	1 state of internal operation	W:W Stack (L)	W:W Stack (H)	W:W Stack (EXR)	R:W:M VEC	R:W VEC+2	1 state of R:W * ⁶ internal operation		

Notes: *1 EAs is the ER5 value and EAd the ER6 value. 1 is added to each of them after execution.

n is the initial value of R4L or R4, and the processing is not executed when n = 0.

*2 Repeated two times when two registers are stored/retrieved, three times when three registers are stored/retrieved, and four times when four registers are stored/retrieved.

*3 Start address on returning.

*4 Start address of program.

*5 Prefetch address that is obtained by adding 2 to the saved PC.

Reading is not performed on returning from sleep mode or software standby mode, and this is regarded as internal operation.

*6 Start address of interrupt handling routine.

*7 Registers ER0, ER1, ER4, and ER5 are used for a TAS instruction.

*8 Registers ER0 to ER6 are used for an STM/LDM instruction.
