SAMSUNG Electronics will evaluate and reply to your requests and questions about device. If you have any questions, please contact the SAMSUNG branch office near you.

**Multi-Chip Package MEMORY****64M Bit (8Mx8/4Mx16) Dual Bank NOR Flash / 128M Bit (8Mx16) NAND Flash / 32M Bit (2Mx16) U<sub>t</sub>RAM****FEATURES**

- Power Supply Voltage : 2.7V~3.1V
- Organization
  - NOR Flash : 8,388,608 x 8 bit / 4,194,304 x 16 bit
  - NAND Flash : (8M + 256K)bit x 16bit
  - U<sub>t</sub>RAM : 2Mbit x 16 bit
- Access Time
  - NOR Flash : 70ns(Max.)
  - NAND Flash : Random : 10us(Max.), Serial : 50ns(Min.)
  - U<sub>t</sub>RAM : 85ns
- Power Consumption (typical value)
  - NOR Flash Read Current : 14mA (@5MHz)
    - Program/Erase Current : 15mA
    - Read while Program or Read while Erase : 35mA
    - Standby Mode/Autosleep Mode : 10μA
  - NAND Flash Read Current : 10mA(@20MHz)
    - Program/Erase Current : 10mA
    - Standby Current : 10μA
  - U<sub>t</sub>RAM Operating Current : 30mA
  - Standby Current : 80μA
- NOR Flash Secode(Security Code) Block : Extra 64KB Block
- NOR Flash Block Group Protection / Unprotection
- NOR Flash Bank Size : 16Mb / 48Mb , 32Mb / 32Mb
- NAND Flash Automatic Program and Erase
  - Page Program: (256 + 8)Word, Block Erase: (8K + 256)Word
- NAND Flash Fast Write Cycle Time
  - Program time : 200μs(Typ.)
  - Block Erase Time : 2ms(Typ.)
- Endurance
  - NOR : 100,000 Program/Erase Cycles Minimum
  - NAND : 100,000 Program/Erase Cycles Minimum with ECC
  - : 1,000 Program/Erase Cycles Maximum without ECC
- Data Retention : 10 years
- Operating Temperature : -25°C ~ 85°C
- Package : 80 - Ball TBGA Type - 8 x 12mm, 0.8 mm pitch

**BALL CONFIGURATION**

**80 Ball TBGA , 0.8mm Pitch  
Top View (Ball Down)**

**GENERAL DESCRIPTION**

The KAB0xD100M featuring single 3.0V power supply is a Multi Chip Package Memory which combines 64Mbit NOR Flash, 128Mbit NAND Flash and 32Mbit Unit Transistor CMOS RAM. 64Mbit NOR Flash memory is organized as 8M x8 or 4M x16 bit, 128Mbit NAND Flash memory is organized as 8M x16 bit and 32Mbit U<sub>t</sub>RAM is organized as 2M x16 bit. The memory architecture of NOR Flash memory is designed to divide its memory arrays into 135 blocks and this provides highly flexible erase and program capability. This device is capable of reading data from one bank while programming or erasing in the other bank with dual bank organization. NOR Flash memory performs a program operation in units of 8 bits (Byte) or 16 bits (Word) and erases in units of a block. Single or multiple blocks can be erased. The block erase operation is completed for typically 0.7sec.

In 128Mbit NAND Flash a 256-word page program can be typically achieved within 200μs and an 8K-word block erase can be typically achieved within 2ms. In serial read operation, a byte can be read by 50ns. DQ pins serve as the ports for address and data input/output as well as command inputs. The KAB0xD100M is suitable for the memory of mobile communication system to reduce not only mount area but also power consumption. This device is available in 80-ball TBGA package.

**BALL DESCRIPTION**

Ball Name	Description
A0 to A20	Address Input Balls (NOR, U <sub>t</sub> RAM)
A-1, A21	Address Input Balls (NOR)
DQ0 to DQ7	Data Input/Output Balls (Common)
DQ8 to DQ15	Data Input/Output Balls (Common)
Vcc <sub>R</sub>	Power Supply (NOR)
Vcc <sub>F</sub>	Power Supply (NAND)
Vcc <sub>U</sub>	Power Supply (U <sub>t</sub> RAM)
VccQ <sub>U</sub>	Data Output Buffer Power (U <sub>t</sub> RAM)
Vss	Ground (Common)
WE	Write Enable (Common)
OE	Output Enable (NOR,U <sub>t</sub> RAM)
CE <sub>R</sub>	Chip Enable (NOR)
CE <sub>F</sub>	Chip Enable (NAND)
CS <sub>U</sub>	Chip Enable (U <sub>t</sub> RAM)
RESET	Hardware Reset (NOR)
WP/ACC	Hardware Write Protection/Program Acceleration (NOR)
BYTE	Byte Control (NOR)
R/B <sub>R</sub>	Read/Busy (NOR)
WP	Write Protection (NAND)
CLE	Command Latch Enable(NAND)
ALE	Address Latch Enable(NAND)
R/B <sub>F</sub>	Read/Busy (NAND)
RE	Output Enable (NAND)
ZZ	Deep Power Down (U <sub>t</sub> RAM)
UB	Upper Byte Enable (U <sub>t</sub> RAM)
LB	Lower Byte Enable (U <sub>t</sub> RAM)
N.C	No Connection
DNU	Do Not Use

NOTE: The bank address bits are A21 ~ A20 for KAB01D100, A21 for KAB04D100.

Table 4. Secode Block Addresses for Bottom Boot Devices

Device	Block Address A21-A12	Block Size	(X8) Address Range	(X16) Address Range
KAB01D100/KAB03D100	0000000xxx	64/32	000000H-00FFFFH	000000H-007FFFH

## NOR FLASH MEMORY COMMAND DEFINITIONS

The NOR Flash Memory operates by selecting and executing its operational modes. Each operational mode has its own command set. In order to select a certain mode, a proper command with specific address and data sequences must be written into the command register. Writing incorrect information which include address and data or writing an improper command will reset the device to the read mode. The defined valid register command sequences are stated in Table 5. Note that Erase Suspend (B0H) and Erase Resume (30H) commands are valid only while the Block Erase Operation is in progress.

Table 5. Command Sequences

Command Sequence		Cycle	1st Cycle		2nd Cycle		3rd Cycle		4th Cycle		5th Cycle		6th Cycle	
			Word	Byte	Word	Byte	Word	Byte	Word	Byte	Word	Byte	Word	Byte

	Data		30H											
CFI Query (6)	Addr	1	55H	AAH										
	Data		98H											

- NOTES:**
1. RA : Read Address, PA : Program Address, RD : Read Data, PD : Program Data  
DA : Dual Bank Address (A20 - A21), BA : Block Address (A12 - A21), X = Don't care .
  2. To terminate the Autoselect Mode, it is necessary to write Reset command to the register.
  3. The 4th cycle data of Autoselect mode is output data.  
The 3rd and 4th cycle bank addresses of Autoselect mode must be same.
  4. The Read / Program operations at non-erasing blocks and the autoselect mode are allowed in the Erase Suspend mode.
  5. The Erase Suspend command is applicable only to the Block Erase operation.
  6. Command is valid when the device is in read mode or Autoselect mode.
  7. DQ8 - DQ15 are don't care in command sequence, but RD and PD is excluded.
  8. A11 - A21 are also don't care, except for the case of special notice.

**Table 6. NOR Flash Memory Autoselect Codes**

Description	DQ8 to DQ15		DQ7 to DQ0
	BYTE = V <sub>IH</sub>	BYTE = V <sub>IL</sub>	
Manufacturer ID	X	X	ECH
Device Code KAB02D100 (Top Boot Block)	22H	X	E0H
Device Code KAB01D100 (Bottom Boot Block)	22H	X	E2H
Device Code KAB04D100 (Top Boot Block)	22H	X	E1H
Device Code KAB03D100 (Bottom Boot Block)	22H	X	E3H
Block Protection Verification	X	X	01H (Protected), 00H (Unprotected)
Secode Block Indicator Bit (DQ7)	X	X	80H (Factory locked), 00H (Not factory locked)

- NOTES:**
1. L=Logic Low=V<sub>IL</sub>, H=Logic High=V<sub>IH</sub>, DA=Dual Bank Address, BA=Block Address, X=Don't care.
  2. Secode Block : Security Code Block.

## NAND FLASH PRODUCT INTRODUCTION

The NAND Flash Memory is a 132Mbit(138,412,032 bit) memory organized as 32,768 rows(pages) by 264 columns. Spare 8 columns are located in 256 to 263 column address. A 264-word data register is connected to memory cell arrays accommodating data transfer between the I/O buffers and memory during page read and page program operations. The memory array is made up of 16 cells that are serially connected like NAND structure. Each of the 16 cells resides in a different page. A block consists of the 32 pages formed by one NAND structures, totaling 8,448 NAND structures of 16 cells. The array organization is shown in Figure 2. Program and read operations are executed on a page basis, while erase operation is executed on a block basis. The memory array consists of 1024 blocks, and a block is separately erasable by 8K-word unit. It indicates that the bit by bit erase operation is prohibited on the NAND Flash Memory.

The NAND Flash Memory has addresses multiplexed with lower 8 I/O's. The NAND Flash Memory allows sixteen bit wide data transfer into and out of page registers. This scheme dramatically reduces pin counts and allows systems upgrades to future densities by maintaining consistency in system board design. Command, address and data are all written through I/O's by bringing WE to low while CE is low. Data is latched on the rising edge of WE. Command Latch Enable(CLE) and Address Latch Enable(ALE) are used to multiplex command and address respectively, via the I/O pins. All commands require one bus cycle except Page Program command and Block Erase command which require two cycles: one cycle for setup and another for execution. The 8M word physical space requires 24 addresses, thereby requiring three cycles for byte-level addressing: column address, low row address and high row address, in that order. Page Read and Page Program need the same three address cycles following required command input. In Block Erase operation, however, only two row address cycles are used. Device operations are selected by writing specific commands into command register. Table 7 defines the specific commands of the NAND Flash Memory.

**Table 7. Command Sets**

Function	1st. Cycle	2nd. Cycle	Acceptable Command during Busy
Read 1	00h	-	
Read 2	50h	-	
Read ID	90h	-	
Reset	FFh	-	O
Page Program	80h	10h	
Block Erase	60h	D0h	
Read Status	70h	-	O

**Table 8. NOR Flash Operations Table**

Operation		$\overline{CE}_R$	$\overline{OE}$	$\overline{WE}$	$\overline{BYTE}$	$\overline{WP}/\overline{ACC}$	A9	A6	A1	A0	DQ15/ A-1	DQ8/ DQ14	DQ0/ DQ7	$\overline{RESET}$

Enable Block Group Protect (3)		L	H	L	X	L/H	X	L	H	L	X	X	DIN	V <sub>ID</sub>
Enable Block Group Unprotect (3)		L	H	L	X	(4)	X	H	H	L	X	X	DIN	V <sub>ID</sub>
Temporary Block Group		X	X	X	X	(4)	X	X	X	X	X	X	X	V <sub>ID</sub>

**NOTES:**

1. L =  $V_{IL}$  (Low), H =  $V_{IH}$  (High),  $V_{ID}$  = 8.5V~12.5V,  $D_{IN}$  = Data in,  $D_{OUT}$  = Data out, X = Don't care.
2.  $\overline{WP}/ACC$  and  $\overline{RESET}$  pin are asserted at  $V_{CCR} \pm 0.3$  V or  $V_{SS} \pm 0.3$  V in the Stand-by mode.
3. Addresses must be composed of the Block address (A12 - A21).  
The Block Protect and Unprotect operations may be implemented via programming equipment too.  
Refer to the "Block Group Protection and Unprotection".
4. If  $\overline{WP}/ACC = V_{IL}$ , the two outermost boot blocks is protected. If  $\overline{WP}/ACC = V_{IH}$ , the two outermost boot block protection depends on whether those blocks were last protected or unprotected using the method described in "Block Group Protection and Unprotection". If  $\overline{WP}/ACC = V_{HH}$ , all blocks will be temporarily unprotected.

**Table 9. NAND Flash Operations Table**

CLE	ALE	$\overline{CE}_R$	$\overline{WE}$	RE	WP	Mode	
H	L	L		H	X	Read Mode	Command Input
L	H	L		H	X		Address Input(3clock)
H	L	L		H	H	Write Mode	Command Input
L	H	L		H	H		Address Input(3clock)
L	L	L		H	H	Data Input	
L	L	L	H		X	Data Output	
X	X	X	X	H	X	During Read(Busy)	
X	X	X	X	X	H	During Program(Busy)

## NOR FLASH DEVICE OPERATION

### Byte/Word Mode

If the  $\overline{\text{BYTE}}$  pin is set at logical "1", the device is in word mode, DQ0-DQ15 are active. Otherwise the  $\overline{\text{BYTE}}$  pin is set at logical "0", the device is in byte mode, DQ0-DQ7 are active. DQ8-DQ14 are in the High-Z state and DQ15 pin is used as an input for the LSB (A-1) address pin.

### Read Mode

The NOR Flash memory is controlled by Chip Enable ( $\overline{\text{CE}}_{\text{R}}$ ), Output Enable ( $\overline{\text{OE}}$ ) and Write Enable ( $\overline{\text{WE}}$ ). When  $\overline{\text{CE}}_{\text{R}}$  and  $\overline{\text{OE}}$  are low and  $\overline{\text{WE}}$  is high, the data stored at the specified address location, will be the output of the device. The outputs are in high impedance state whenever  $\overline{\text{CE}}_{\text{R}}$  or  $\overline{\text{OE}}$  is high.

### Standby Mode

The NOR Flash memory features Stand-by Mode to reduce power consumption. This mode puts the device on hold when the device is deselected by making  $\overline{\text{CE}}_{\text{R}}$  high ( $\overline{\text{CE}}_{\text{R}} = V_{\text{IH}}$ ). Refer to the DC characteristics for more details on stand-by modes.

### Output Disable

The device outputs are disabled when  $\overline{\text{OE}}$  is High ( $\overline{\text{OE}} = V_{\text{IH}}$ ). The output pins are in high impedance state.

### Automatic Sleep Mode

The NOR Flash Memory features Automatic Sleep Mode to minimize the device power consumption. Since the device typically draws 5 $\mu\text{A}$  of the current in Automatic Sleep Mode, this feature plays an extremely important role in battery-powered applications. When addresses remain steady for  $t_{\text{AA}} + 50\text{ns}$ , the device automatically activates the Automatic Sleep Mode. In the sleep mode, output data is latched and always available to the system. When addresses are changed, the device provides new data without wait time.

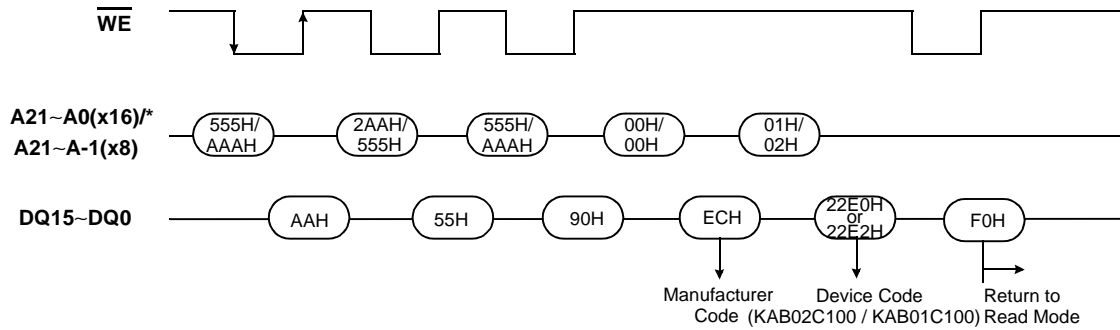

Figure 3. Auto Sleep Mode Operation

### Autoselect Mode

The NOR Flash memory offers the Autoselect Mode to identify manufacturer and device type by reading a binary code. The Autoselect Mode allows programming equipment to automatically match the device to be programmed with its corresponding programming algorithm. In addition, this mode allows the verification of the status of write protected blocks. The manufacturer and device code can be read via the command register. The Command Sequence is shown in Table 5 and Figure 4. The autoselect operation of block protect verification is initiated by first writing two unlock cycle. The third cycle must contain the bank address and autoselect command (90H). If Block address while (A6, A1, A0) = (0,1,0) is finally asserted on the address ball, it will produce a logical "1" at the device output DQ0 to indicate a write protected block or a logical "0" at the device output DQ0 to indicate a write unprotected block. To terminate the autoselect operation, write Reset command (F0H) into the command register.

**NOTE:** The 3rd Cycle and 4th Cycle address must include the same bank address. Please refer to Table 6 for device code.

**Figure 4. Autoselect Operation**

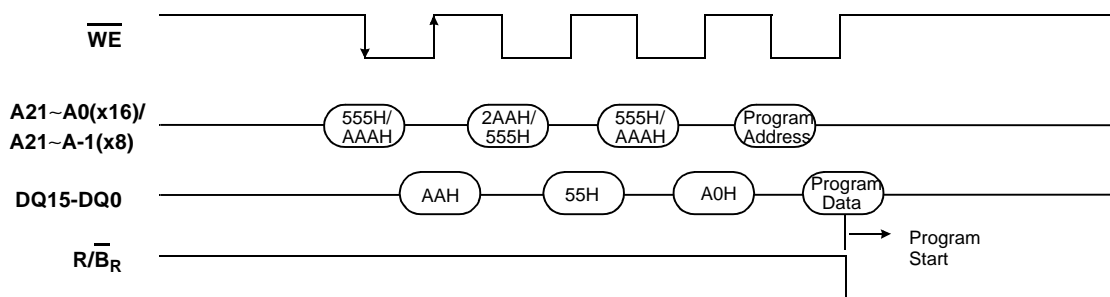

### Write (Program/Erase) Mode

The NOR Flash memory executes its program/erase operations by writing commands into the command register. In order to write the commands to the register,  $\overline{CE}_R$  and  $\overline{WE}$  must be low and  $\overline{OE}$  must be high. Addresses are latched on the falling edge of  $\overline{CE}_R$  or  $\overline{WE}$  (whichever occurs last) and the data are latched on the rising edge of  $\overline{CE}_R$  or  $\overline{WE}$  (whichever occurs first). The device uses standard microprocessor write timing.

### Program

The NOR Flash memory can be programmed in units of a word or a byte. Programming is writing 0's into the memory array by executing the Internal Program Routine. In order to perform the Internal Program Routine, a four-cycle command sequence is necessary. The first two cycles are unlock cycles. The third cycle is assigned for the program setup command. In the last cycle, the address of the memory location and the data to be programmed at that location are written. The device automatically generates adequate program pulses and verifies the programmed cell margin by the Internal Program Routine. During the execution of the Routine, the system is not required to provide further controls or timings.

During the Internal Program Routine, commands written to the device will be ignored. Note that a hardware reset during a program operation will cause data corruption at the corresponding location.

**Figure 5. Program Command Sequence**

## Unlock Bypass

The NOR Flash memory provides the unlock bypass mode to save its program time. The mode is invoked by the unlock bypass command sequence. Unlike the standard program command sequence that contains four bus cycles, the unlock bypass program command sequence comprises only two bus cycles.

The unlock bypass mode is engaged by issuing the unlock bypass command sequence which is comprised of three bus cycles. Writing first two unlock cycles is followed by a third cycle containing the unlock bypass command (20H). Once the device is in the unlock bypass mode, the unlock bypass program command sequence is necessary to program in this mode. The unlock bypass program command sequence is comprised of only two bus cycles; writing the unlock bypass program command (A0H) is followed by the program address and data. This command sequence is the only valid one for programming the device in the unlock bypass mode.

The unlock bypass reset command sequence is the only valid command sequence to exit the unlock bypass mode. The unlock bypass reset command sequence consists of two bus cycles. The first cycle must contain the data (90H). The second cycle contains only the data (00H). Then, the device returns to the read mode.

## Chip Erase

To erase a chip is to write 1's into the entire memory array by executing the Internal Erase Routine. The Chip Erase requires six bus cycles to write the command sequence. The erase set-up command is written after first two "unlock" cycles. Then, there are two more write cycles prior to writing the chip erase command. The Internal Erase Routine automatically pre-programs and verifies the entire memory for an all zero data pattern prior to erasing. The automatic erase begins on the rising edge of the last WE or CE<sub>R</sub> pulse in the command sequence and terminates when DQ7 is "1". After that the device returns to the read mode.

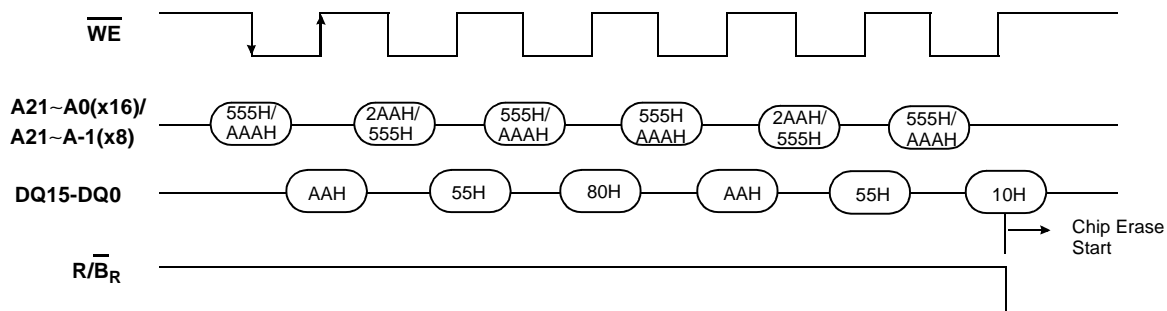

Figure 6. Chip Erase Command Sequence

## Block Erase

To erase a block is to write 1's into the desired memory block by executing the Internal Erase Routine. The Block Erase requires six bus cycles to write the command sequence shown in Table 5. After the first two "unlock" cycles, the erase setup command (80H) is written at the third cycle. Then there are two more "unlock" cycles followed by the Block Erase command. The Internal Erase Routine automatically pre-programs and verifies the entire memory prior to erasing it. The block address is latched on the falling edge of WE or CE<sub>R</sub>, while the Block Erase command is latched on the rising edge of WE or CE<sub>R</sub>.

Multiple blocks can be erased sequentially by writing the six bus-cycle operation in Fig 7. Upon completion of the last cycle for the Block Erase, additional block address and the Block Erase command (30H) can be written to perform the Multi-Block Erase. An 50us (typical) "time window" is required between the Block Erase command writes. The Block Erase command must be written within the 50us "time window", otherwise the Block Erase command will be ignored. The 50us "time window" is reset when the falling edge of the WE occurs within the 50us of "time window" to latch the Block Erase command. During the 50us of "time window", any command other than the Block Erase or the Erase Suspend command written to the device will reset the device to read mode. After the 50 us of "time window", the Block Erase command will initiate the Internal Erase Routine to erase the selected blocks. Any Block Erase address and command following the exceeded "time window" may or may not be accepted. No other commands will be recognized except the Erase Suspend command.

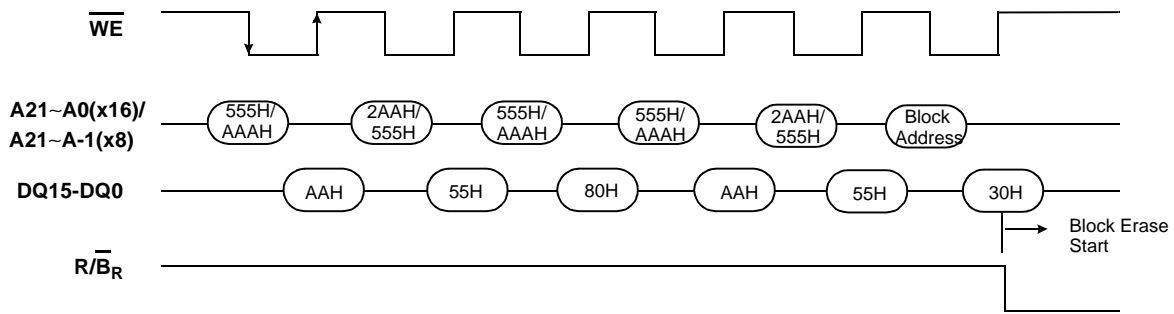

Figure 7. Block Erase Command Sequence

### Erase Suspend / Resume

The Erase Suspend command interrupts the Block Erase to read or program data in a block that is not being erased. The Erase Suspend command is only valid during the Block Erase operation including the time window of 50μs. The Erase Suspend command is not valid while the Chip Erase or the Internal Program Routine sequence is running.

When the Erase Suspend command is written during a Block Erase operation, the device requires a maximum of 20μs to suspend the erase operation. But, when the Erase Suspend command is written during the block erase time window (50μs), the device immediately terminates the block erase time window and suspends the erase operation.

After the erase operation has been suspended, the device is available for reading or programming data in a block that is not being erased. The system may also write the autoselect command sequence when the device is in the Erase Suspend mode.

When the Erase Resume command is executed, the Block Erase operation will resume. When the Erase Suspend or Erase Resume command is executed, the addresses are in Don't Care state.

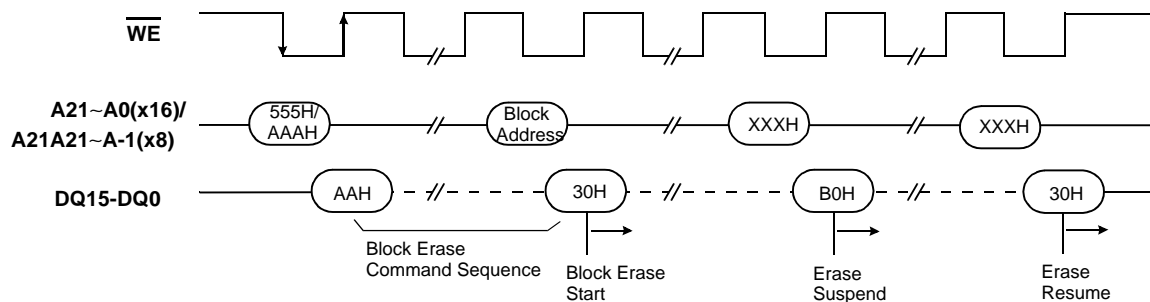

Figure 8. Erase Suspend/Resume Command Sequence

## Read While Write

The NOR Flash memory provides dual bank memory architecture that divides the memory array into two banks. The device is capable of reading data from one bank and writing data to the other bank simultaneously. This is so called the Read While Write operation with dual bank architecture; this feature provides the capability of executing the read operation during Program/Erase or Erase-Suspend-Program operation.

The Read While Write operation is prohibited during the chip erase operation. It is also allowed during erase operation when either single block or multiple blocks from same bank are loaded to be erased. It means that the Read While Write operation is prohibited when blocks from Bank1 and another blocks from Bank2 are loaded all together for the multi-block erase operation.

## Block Group Protection & Unprotection

The NOR Flash memory feature hardware block group protection. This feature will disable both program and erase operations in any combination of forty one block groups of memory. Please refer to Tables 12 and 13. The block group protection feature is enabled using programming equipment at the user's site. The device is shipped with all block groups unprotected.

This feature can be hardware protected or unprotected. If a block is protected, program or erase command in the protected block will be ignored by the device. The protected block can only be read. This is useful method to preserve an important program data. The block group unprotection allows the protected blocks to be erased or programmed. All blocks must be protected before unprotect operation is executing. The block protection and unprotection can be implemented by the following method.

**Table 11. Block Group Protection & Unprotection**

Operation	$\overline{\text{CE}}_{\text{R}}$	$\overline{\text{OE}}$	$\overline{\text{WE}}$	$\overline{\text{BYTE}}$	A9	A6	A1	A0	DQ15/ A-1	DQ8/ DQ14	DQ0/ DQ7	$\overline{\text{RESET}}$
Block Group Protect	L	H	L	X	X	L	H	L	X	X	D <sub>IN</sub>	V <sub>ID</sub>
Block Group Unprotect	L	H	L	X	X	H	H	L	X	X	D <sub>IN</sub>	V <sub>ID</sub>

Address must be inputted to the block group address (A12~A21) during block group protection operation. Please refer to Figure 10 (Algorithm) and Switching Waveforms of Block Group Protect & Unprotect Operations.

## Temporary Block Group Unprotect

The protected blocks of the NOR Flash memory can be temporarily unprotected by applying high voltage ( $V_{\text{ID}} = 8.5\text{V} \sim 12.5\text{V}$ ) to the RESET ball. In this mode, previously protected blocks can be programmed or erased with the program or erase command routines. When the RESET ball goes high ( $\text{RESET} = V_{\text{IH}}$ ), all the previously protected blocks will be protected again. If the WP/ACC ball is asserted at  $V_{\text{IL}}$ , the two outermost boot blocks remain protected.

**Figure 9. Temporary Block Group Unprotect Sequence**

**NOTE:** All blocks must be protected before unprotect operation is executing.

**Figure 10. Block Group Protection & Unprotection Algorithms**

## Write Protect ( $\overline{\text{WP}}$ )

The  $\overline{\text{WP}}/\text{ACC}$  ball has two useful functions. The one is that certain boot block is protected by the hardware method not to use  $\text{V}_{\text{ID}}$ . The other is that program operation is accelerated to reduce the program time (Refer to Accelerated program Operation Paragraph). When the  $\text{WP}/\text{ACC}$  ball is asserted at  $\text{V}_{\text{IL}}$ , the device can not perform program and erase operation in the two "outermost" 8K byte boot blocks independently of whether those blocks were protected or unprotected using the method described in "Block Group protection/Unprotection".

The write protected blocks can only be read. This is useful method to preserve an important program data.

The two outermost 8K byte boot blocks are the two blocks containing the lowest addresses in a bottom-boot-configured device, or the two blocks containing the highest addresses in a top-boot-configured device.

(KAB02D100/KAB04D100 : BA133 and BA134, KAB01D100/KAB03D100 : BA0 and BA1)

When the  $\text{WP}/\text{ACC}$  ball is asserted at  $\text{V}_{\text{IH}}$ , the device reverts to whether the two outermost 8K byte boot blocks were last set to be protected or unprotected. That is, block protection or unprotection for these two blocks depends on whether they were last protected or unprotected using the method described in "Block Group protection/unprotection".

Recommend that the  $\text{WP}/\text{ACC}$  ball must not be in the state of floating or unconnected, otherwise the device may be led to malfunction.

## Secode(Security Code) Block Region

The Secode Block feature provides a NOR Flash memory region to be stored unique and permanent identification code, that is, Electronic Serial Number (ESN), customer code and so on. This is primarily intended for customers who wish to use an Electronic Serial Number (ESN) in the device with the ESN protected against modification. Once the Secode Block region is protected, any further modification of that region is impossible. This ensures the security of the ESN once the product is shipped to the field.

The Secode Block is factory locked or customer lockable. Before the device is shipped, the factory locked Secode Block is written on the special code and it is protected. The Secode Indicator bit (DQ7) is permanently fixed at "1" and it is not changed. The customer lockable Secode Block is unprotected, therefore it is programmed and erased. The Secode Indicator bit (DQ7) of it is permanently fixed at "0" and it is not changed, but once it is protected, there is no procedure to unprotect and modify the Secode Block.

The Secode Block region is 64K bytes in length and is accessed through a new command sequence (see Table 8). After the system has written the Enter Secode Block command sequence, the system may read the Secode Block region by using the same addresses of the boot blocks (8KBx8). The KAB02D100/KAB04D100 occupies the address of the byte mode 7F0000H to 7FFFFFFH (word mode 3F8000H to 3FFFFFFH) and the KAB01D100/KAB03D100 type occupies the address of the byte mode 000000H to 00FFFFFFH (word mode 000000H to 007FFFFH). This mode of operation continues until the system issues the Exit Secode Block command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to read mode.

## Accelerated Program Operation

Accelerated program operation reduces the program time through the ACC function. This is one of two functions provided by the  $\overline{\text{WP}}/\text{ACC}$  ball. When the  $\text{WP}/\text{ACC}$  ball is asserted as  $\text{V}_{\text{HH}}$ , the device automatically enters the aforementioned Unlock Bypass mode, temporarily unprotecting any protected blocks, and reduces the program operation time. The system would use a two-cycle program command sequence as required by the Unlock Bypass mode. Removing  $\text{V}_{\text{HH}}$  from the  $\text{WP}/\text{ACC}$  ball returns the device to normal operation. **Recommend that the  $\text{WP}/\text{ACC}$  ball must not be asserted at  $\text{V}_{\text{HH}}$  except on accelerated program operation, or the device may be damaged. In addition, the  $\text{WP}/\text{ACC}$  ball must not be in the state of floating or unconnected, otherwise the device may be led to malfunction.**

## Software Reset

The reset command provides that the device is reseted to read mode or erase-suspend-read mode. The addresses are in Don't Care state. The reset command is valid between the sequence cycles in an erase command sequence before erasing begins, or in a program command sequence before programming begins. This resets the bank in which was operating to read mode. If the device is be erasing or programming, the reset command is invalid until the operation is completed. Also, the reset command is valid between the sequence cycles in an autoselect command sequence. In the autoselect mode, the reset command returns the bank to read mode. If a bank entered the autoselect mode in the Erase Suspend mode, the reset command returns the bank to erase-suspend-read mode. If DQ5 is high on erase or program operation, the reset command return the bank to read mode or erase-suspend-read mode if the bank was in the Erase Suspend state.

### Hardware Reset

The NOR Flash memory offers a reset feature by driving the  $\overline{\text{RESET}}$  ball to  $V_{IL}$ . The  $\overline{\text{RESET}}$  ball must be kept low ( $V_{IL}$ ) for at least 500ns. When the  $\overline{\text{RESET}}$  ball is driven low, any operation in progress will be terminated and the internal state machine will be reset to the standby mode after 20 $\mu$ s. If a hardware reset occurs during a program operation, the data at that particular location will be lost. Once the  $\overline{\text{RESET}}$  ball is taken high, the device requires 200ns of wake-up time until outputs are valid for read access. Also, note that all the data output balls are tri-stated for the duration of the  $\overline{\text{RESET}}$  pulse.

The  $\overline{\text{RESET}}$  ball may be tied to the system reset ball. If a system reset occurs during the Internal Program and Erase Routine, the device will be automatically reset to the read mode; this will enable the systems microprocessor to read the boot-up firmware from the NOR Flash memory.

### Power-up Protection

To avoid initiation of a write cycle during  $V_{CCR}$  Power-up,  $\overline{\text{RESET}}$  low must be asserted during power-up. After  $\overline{\text{RESET}}$  goes high, the device is reset to the read mode.

### Low $V_{CCR}$ Write Inhibit

To avoid initiation of a write cycle during  $V_{CCR}$  power-up and power-down, a write cycle is locked out for  $V_{CCR}$  less than 1.8V. If  $V_{CCR} < V_{LKO}$  (Lock-Out Voltage), the command register and all internal program/erase circuits are disabled. Under this condition the device will reset itself to the read mode. Subsequent writes will be ignored until the  $V_{CCR}$  level is greater than  $V_{LKO}$ . It is the user's responsibility to ensure that the control balls are logically correct to prevent unintentional writes when  $V_{CCR}$  is above 1.8V.

### Write Pulse Glitch Protection

Noise pulses of less than 5ns(typical) on  $\overline{\text{CE}}_R$ ,  $\overline{\text{OE}}$ , or  $\overline{\text{WE}}$  will not initiate a write cycle.

### Logical Inhibit

Writing is inhibited under any one of the following conditions :  $\overline{\text{OE}} = V_{IL}$ ,  $\overline{\text{CE}}_R = V_{IH}$  or  $\overline{\text{WE}} = V_{IH}$ . To initiate a write,  $\overline{\text{CE}}_R$  and  $\overline{\text{WE}}$  must be "0", while  $\overline{\text{OE}}$  is "1".

### Common NOR Flash Memory Interface

Common Flash Memory Interface is contrived to increase the compatibility of host system software. It provides the specific information of the device, such as memory size, byte/word configuration, and electrical features. Once this information has been obtained, the system software will know which command sets to use to enable flash writes, block erases, and control the flash component. When the system writes the CFI command(98H) to address 55H in word mode(or address AAH in byte mode), the device enters the CFI mode. And then if the system writes the address shown in Table 14, the system can read the CFI data. Query data are always presented on the lowest-order data outputs(DQ0-7) only. In word(x16) mode, the upper data outputs(DQ8-15) is 00h. To terminate this operation, the system must write the reset command.

Table 14. Common NOR Flash Memory Interface Code

Description	Addresses (Word Mode)	Addresses (Byte Mode)	Data
Query Unique ASCII string "QRY"	10H 11H 12H	20H 22H 24H	0051H 0052H 0059H
Primary OEM Command Set	13H 14H	26H 28H	0002H 0000H
Address for Primary Extended Table	15H 16H	2AH 2CH	0040H 0000H

**NOTE:**

- The number of blocks in Bank2 is device dependent.  
KAB02D100/KAB04D100(16Mb/48Mb) = 60h (96blocks)  
KAB01D100/KAB03D100(32Mb/32Mb) = 40h (64blocks)

## NOR FLASH DEVICE STATUS FLAGS

The NOR Flash memory has means to indicate its status of operation in the bank where a program or erase operation is in progress. Address must include bank address being executed internal routine operation. The status is indicated by raising the device status flag via corresponding DQ balls or the R/B<sub>R</sub> ball. The corresponding DQ balls are DQ7, DQ6, DQ5, DQ3 and DQ2. The status is as follows :

**Table 15. Hardware Sequence Flags**

	Status	DQ7	DQ6	DQ5	DQ3	DQ2	R/B <sub>R</sub>
In Progress	Programming	$\overline{\text{DQ7}}$	Toggle	0	0	1	0
	Block Erase or Chip Erase	0	Toggle	0	1	Toggle	0
	Erase Suspend Read	Erase Suspended Block	1	1	0	0	Toggle (Note 1)
	Erase Suspend Read	Non-Erase Suspended Block	Data	Data	Data	Data	1
	Erase Suspend Program	Non-Erase Suspended Block	$\overline{\text{DQ7}}$	Toggle	0	0	1
Exceeded Time Limits	Programming	$\overline{\text{DQ7}}$	Toggle	1	0	No Toggle	0
	Block Erase or Chip Erase	0	Toggle	1	1	(Note 2)	0
	Erase Suspend Program	$\overline{\text{DQ7}}$	Toggle	1	0	No Toggle	0

**NOTES:**

1. DQ2 will toggle when the device performs successive read operations from the erase suspended block.
2. If DQ5 is High (exceeded timing limits), successive reads from a problem block will cause DQ2 to toggle.

### DQ7 : $\overline{\text{Data}}$ Polling

When an attempt to read the device is made while executing the Internal Program, the complement of the data is written to DQ7 as an indication of the Routine in progress. When the Routine is completed an attempt to access to the device will produce the true data written to DQ7. When a user attempts to read the device during the Erase operation, DQ7 will be low. If the device is placed in the Erase Suspend Mode, the status can be detected via the DQ7 ball. If the system tries to read an address which belongs to a block that is being erased, DQ7 will be high. If a non-erased block address is read, the device will produce the true data to DQ7. If an attempt is made to program a protected block, DQ7 outputs complements the data for approximately 1μs and the device then returns to the Read Mode without changing data in the block. If an attempt is made to erase a protected block, DQ7 outputs complement data in approximately 100μs and the device then returns to the Read Mode without erasing the data in the block.

### DQ6 : Toggle Bit

Toggle bit is another option to detect whether an Internal Routine is in progress or completed. Once the device is at a busy state, DQ6 will toggle. Toggling DQ6 will stop after the device completes its Internal Routine. If the device is in the Erase Suspend Mode, an attempt to read an address that belongs to a block that is being erased will produce a high output of DQ6. If an address belongs to a block that is not being erased, toggling is halted and valid data is produced at DQ6.

If an attempt is made to program a protected block, DQ6 toggles for approximately 1μs and the device then returns to the Read Mode without changing the data in the block. If an attempt is made to erase a protected block, DQ6 toggles for approximately 100μs and the device then returns to the Read Mode without erasing the data in the block.

### DQ5 : Exceed Timing Limits

If the Internal Program/Erase Routine extends beyond the timing limits, DQ5 will go High, indicating program/erase failure.

### DQ3 : Block Erase Timer

The status of the multi-block erase operation can be detected via the DQ3 pin. DQ3 will go High if 50μs of the block erase time window expires. In this case, the Internal Erase Routine will initiate the erase operation. Therefore, the device will not accept further write commands until the erase operation is completed. DQ3 is Low if the block erase time window is not expired. Within the block erase time window, an additional block erase command (30H) can be accepted. To confirm that the block erase command has been accepted, the software may check the status of DQ3 following each block erase command.

### DQ2 : Toggle Bit 2

The device generates a toggling pulse in DQ2 only if an Internal Erase Routine or an Erase Suspend is in progress. When the device executes the Internal Erase Routine, DQ2 toggles only if an erasing block is read. Although the Internal Erase Routine is in the Exceeded Time Limits, DQ2 toggles only if an erasing block in the Exceeded Time Limits is read. When the device is in the Erase Suspend mode, DQ2 toggles only if an address in the erasing block is read. If a non-erasing block address is read during the Erase Suspend mode, then DQ2 will produce valid data. DQ2 will go High if the user tries to program a non-erase suspend block while the device is in the Erase Suspend mode. Combination of the status in DQ6 and DQ2 can be used to distinguish the erase operation from the program operation.

### $\overline{R/B_R}$ : Ready/Busy

The NOR Flash memory has a Ready / Busy output that indicates either the completion of an operation or the status of Internal Algorithms. If the output is Low, the device is busy with either a program or an erase operation. If the output is High, the device is ready to accept any read/write or erase operation. When the  $\overline{R/B_R}$  pin is low, the device will not accept any additional program or erase commands with the exception of the Erase Suspend command. If the NOR Flash memory is placed in an Erase Suspend mode, the  $\overline{R/B_R}$  output will be High. For programming, the  $\overline{R/B_R}$  is valid ( $\overline{R/B_R} = 0$ ) after the rising edge of the fourth  $\overline{WE}$  pulse in the four write pulse sequence. For Chip Erase,  $\overline{R/B_R}$  is also valid after the rising edge of  $\overline{WE}$  pulse in the six write pulse sequence. For Block Erase,  $\overline{R/B_R}$  is also valid after the rising edge of the sixth  $\overline{WE}$  pulse.

The pin is an open drain output, allowing two or more Ready/ Busy outputs to be OR-tied. An appropriate pull-up resistor is required for proper operation.

$$R_p = \frac{V_{cc} (\text{Max.}) - V_{OL} (\text{Max.})}{I_{OL} + \sum I_L} = \frac{2.7 \text{ V}}{2.1\text{mA} + \sum I_L}$$

where  $\sum I_L$  is the sum of the input currents of all devices tied to the Ready / Busy pin.

Figure 11. Data Polling Algorithms

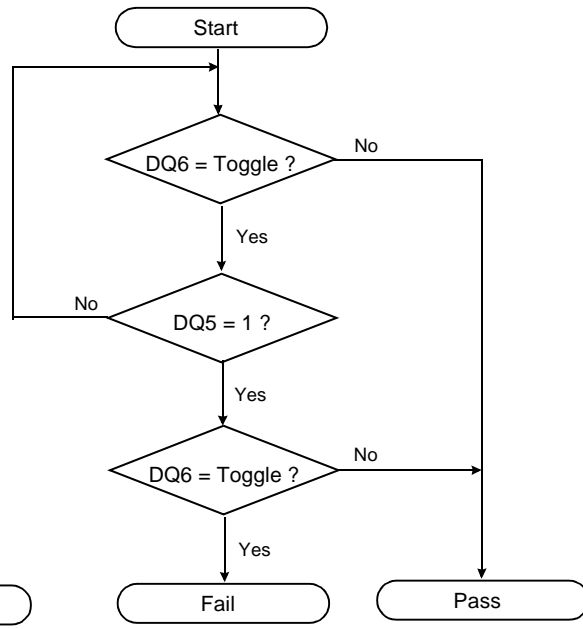

Figure 12. Toggle Bit Algorithms

**NOTES:**

1. All protected block groups are unprotected.  
( If  $\overline{WP}/ACC = V_{IL}$  , the two outermost boot blocks remain protected )
2. All previously protected block groups are protected once again.

Figure 13. Temporary Block Group Unprotect Routine

## NAND FLASH MEMORY OPERATION

### PAGE READ

Upon initial device power up, the device status is initially Read1 command(00h) latched. This operation is also initiated by writing 00h to the command register along with three address cycles. Once the command is latched, it does not need to be written for the following page read operation. Two types of operation are available : random read, serial page read. The random read mode is enabled when the page address is changed. The 264 words of data within the selected page are transferred to the data registers in less than  $10\mu\text{s}(t_R)$ . The system controller can detect the completion of this data transfer( $t_R$ ) by analyzing the output of R/B pin. Once the data in a page is loaded into the registers, they may be read out by sequential  $\overline{\text{RE}}$  pulse of 50n period cycle. High to low transitions of the  $\overline{\text{RE}}$  clock take out the data from the selected column address up to the last column address.

Read1 and Read2 commands determine pointer which selects either main area or spare area. The spare area(256 to 263 words) may be selectively accessed by writing the Read2 command. Addresses A<sub>0</sub> to A<sub>2</sub> set the starting address of spare area while addresses A<sub>3</sub> to A<sub>7</sub> must be "L". To move the pointer back to the main area, Read1 command(00h) is needed. Figures 16 through 21 show typical sequence and timing for each read operation.

Figure 14,15 details the sequence.

**Figure 14. Read1 Operation**

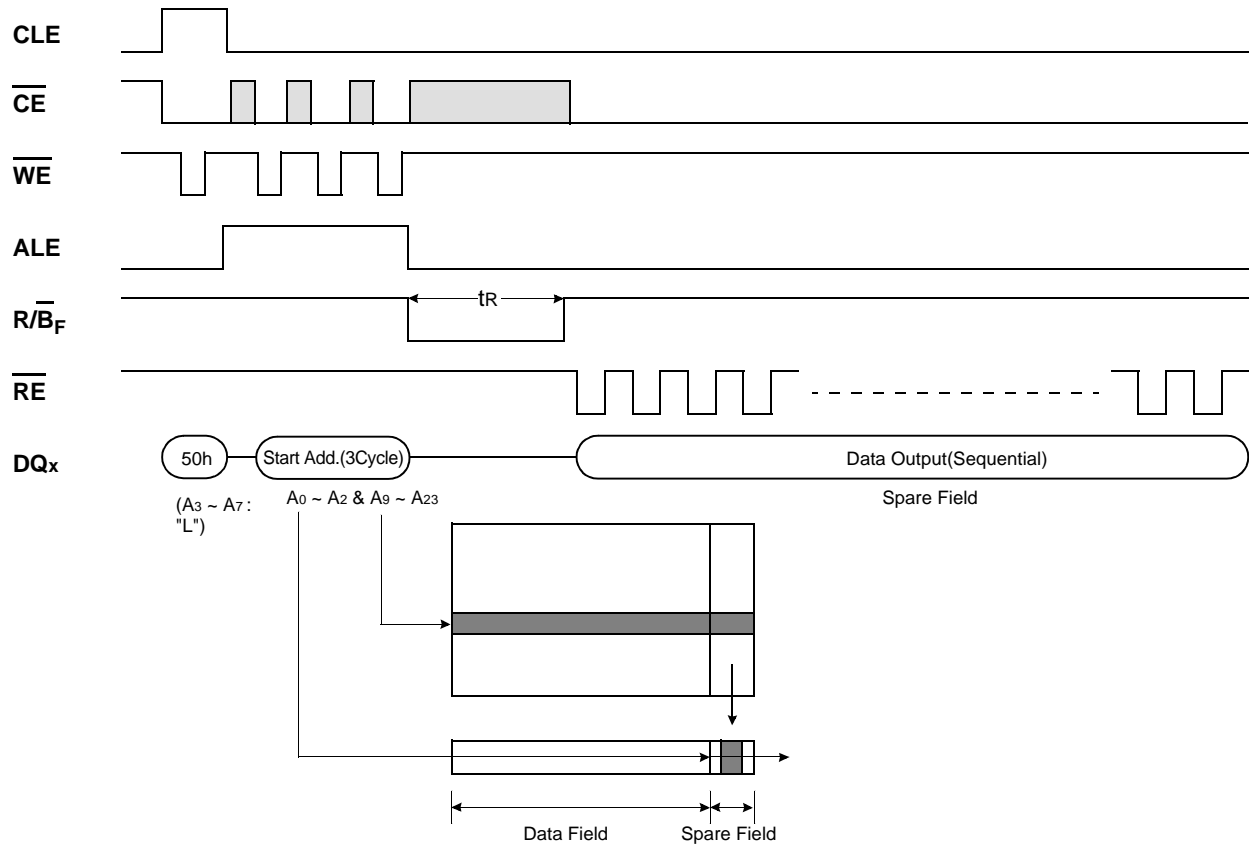

Figure 15. Read2 Operation

## PAGE PROGRAM

The device is programmed basically on a page basis, but it allows multiple partial page program of one word or consecutive words up to 264, in a single page program cycle. The number of consecutive partial page program operation within the same page without intervening erase operation should not exceed 2 for main array and 3 for spare array. The addressing may be done in any random order in a block. Page program cycle consists of a serial data loading (up to 264 words of data) into the page register, and program of loaded data into the appropriate cell. Serial data loading can start in 2nd half array by moving pointer. About the pointer operation, please refer to the attached technical notes. Serial data loading is executed by entering the Serial Data Input command (80h) and three cycle address input and then serial data loading. The bytes except those to be programmed need not to be loaded. The Page Program confirm command (10h) initiates the programming process. Writing 10h alone without previously entering 80h will not initiate program process. The internal write controller automatically executes the algorithms and timings necessary for program and verification, thereby freeing the CPU for other tasks. Once the program process starts, the Read Status Register command may be entered, with RE and CE low, to read the status register. The CPU can detect the completion of a program cycle by monitoring the R/B output, or the Status bit (I/O 6) of the Status Register. Only the Read Status command and Reset command are valid while programming is in progress. When the Page Program is completed, the Write Status Bit (I/O 0) may be checked (Figure 16). The internal write verification detects only errors for "1"s that are not successfully programmed to "0"s. The command register remains in Read Status command mode until another valid command is written to the command register. Figure 16 details the sequence.

Figure 16. Program &amp; Read Status Operation

## BLOCK ERASE

The Erase operation is done on a block(16K Bytes) basis. Block Erase is executed by entering Erase Setup command(60h) and 2 cycle block addresses and Erase Confirm command(D0h). Only address A14 to A23 is valid while A9 to A13 is ignored. This two-step sequence of setup followed by execution command ensures that memory contents are not accidentally erased due to external noise condition. At the rising edge of  $\overline{WE}$  after erase confirm command input, internal write controller handles erase and erase-verification. When the erase operation is completed, the Write Status Bit(I/O 0) may be checked.

Figure 6 details the sequence.

Figure 17. Block Erase Operation

## READ STATUS

The device contains a Status Register which may be read to find out whether program or erase operation is completed, and whether the program or erase operation is completed successfully. After writing 70h command to command register, a read cycle takes out the content of the Status Register to the I/O pins on the falling edge of  $\overline{CE_F}$  or  $\overline{RE}$ . This two line control allows the system to poll the progress of each device in multiple memory connections even when R/B pins are common-wired.  $\overline{RE}$  or  $\overline{CE_F}$  does not need to be toggled for updated status. Refer to table 16 for specific Status Register definitions. The command register remains in Status Read mode until further commands are issued to it. Therefore, if the status register is read during a random read cycle, a read command(00h or 50h) should be given before sequential page read cycle.

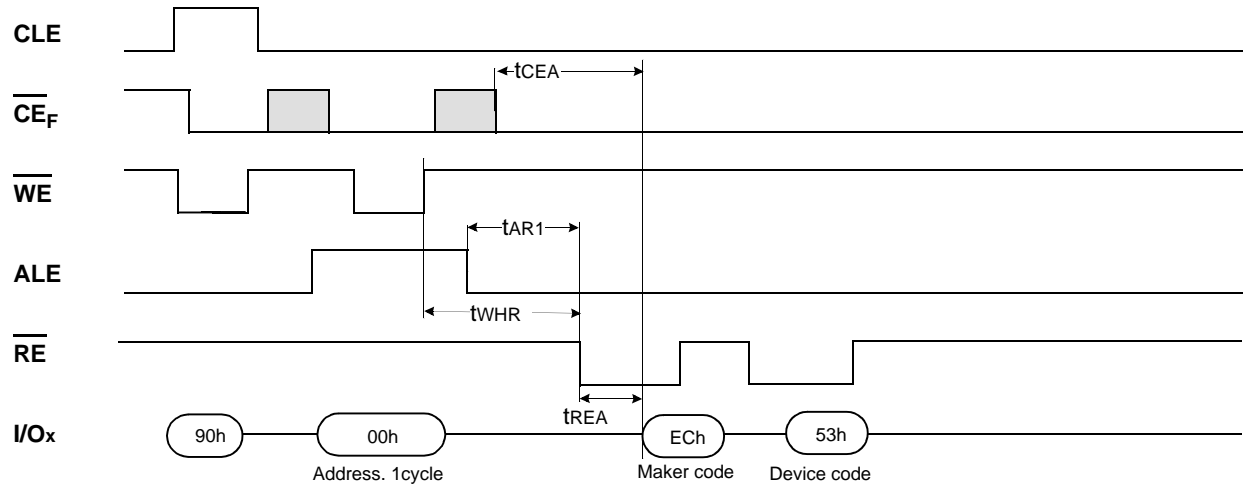

Table 16. Read Status Register Definition

DQ #	Status	Definition
DQ0	Program / Erase	"0" : Successful Program / Erase
		"1" : Error in Program / Erase
DQ1	Reserved for Future Use	"0"
DQ2		"0"
DQ3		"0"
DQ4		"0"
DQ5		"0"
DQ6	Device Operation	"0" : Busy      "1" : Ready
DQ7	Write Protect	"0" : Protected      "1" : Not Protected
DQ8~15	Not use	Don't care

## READ ID

The device contains a product identification mode, initiated by writing 90h to the command register, followed by an address input of 00h. Two read cycles sequentially output the manufacture code(ECh), and the device code (53h) respectively. The command register remains in Read ID mode until further commands are issued to it. Figure 18 shows the operation sequence.

**Figure 18. Read ID Operation**

## RESET

The device offers a reset feature, executed by writing FFh to the command register. When the device is in Busy state during random read, program or erase mode, the reset operation will abort these operations. The contents of memory cells being altered are no longer valid, as the data will be partially programmed or erased. The command register is cleared to wait for the next command, and the Status Register is cleared to value C0h when WP is high. Refer to table 17 for device status after reset operation. If the device is already in reset state, new reset command will not be accepted by the command register. The R/B pin transitions to low for t<sub>RST</sub> after the Reset command is written. Reset command is not necessary for normal operation. Refer to Figure 19 below.

**Figure 19. RESET Operation**

**Table 17. Device Status**

	After Power-up	After Reset
Operation Mode	Read 1	Waiting for next command

**READY/BUSY**

The device has a  $\overline{R/B_F}$  output that provides a hardware method of indicating the completion of a page program, erase and random read completion. The  $\overline{R/B_F}$  pin is normally high but transitions to low after program or erase command is written to the command register or random read is started after address loading. It returns to high when the internal controller has finished the operation. The pin is an open-drain driver thereby allowing two or more  $\overline{R/B_F}$  outputs to be Or-tied. Because pull-up resistor value is related to  $t_r(\overline{R/B_F})$  and current drain during busy( $i_{busy}$ ), an appropriate value can be obtained with the following reference chart(Fig 20). Its value can be determined by the following guidance.

**Figure 20.  $R_p$  vs  $t_r, t_f$  &  $R_p$  vs  $i_{busy}$**

@  $V_{cc} = 3.3V$ ,  $T_a = 25^\circ C$ ,  $C_L = 100pF$

 **$R_p$  value guidance**

$$R_p = \frac{V_{cc}(\text{Max.}) - V_{OL}(\text{Max.})}{I_{OL} + \sum I_L} = \frac{2.7V}{8mA + \sum I_L}$$

where  $I_L$  is the sum of the input currents of all devices tied to the  $\overline{R/B}$  pin.

$R_p(\text{max})$  is determined by maximum permissible limit of  $t_r$

### Data Protection & Powerup sequence

The device is designed to offer protection from any involuntary program/erase during power-transitions. An internal voltage detector disables all functions whenever  $V_{CCF}$  is below about 1.3V.  $\overline{WP}$  pin provides hardware protection and is recommended to be kept at  $V_{IL}$  during power-up and power-down and recovery time of minimum  $1\mu s$  is required before internal circuit gets ready for any command sequences as shown in Figure 21. The two step command sequence for program/erase provides additional software protection.

**Figure 21. AC Waveforms for Power Transition**

**NAND Flash Technical Notes****Invalid Block(s)**

Invalid blocks are defined as blocks that contain one or more invalid bits whose reliability is not guaranteed by Samsung. The information regarding invalid block(s) is so called as the invalid block information. Devices, regardless of having invalid block(s), have the same quality level because all valid blocks have same AC and DC characteristics. An invalid block(s) does not affect the performance of valid block(s) because its bit line and common source line is isolated by a select transistor. The system design must be able to mask out invalid block(s) via address mapping. The 1st block, which is placed on 00h block address, is fully guaranteed to be a valid block, does not require Error Correction.

**Identifying Invalid Block(s)**

All device locations are erased(FFh) except locations where the invalid block(s) information is written prior to shipping. The invalid block(s) status is defined by the 1st and 6th word in the spare area. Samsung makes sure that either 1st and 2nd page of every invalid block has non-FFFFh data at the column address of 256 and 261. Since invalid block information is also erasable in most cases, it is impossible to recover the information once it was erased. Therefore, system must be able to recognize the invalid block(s) based on the original invalid block information and create invalid block table via the following suggested flow chart(Figure 22). Any intentional erasure of the original invalid block information is prohibited.

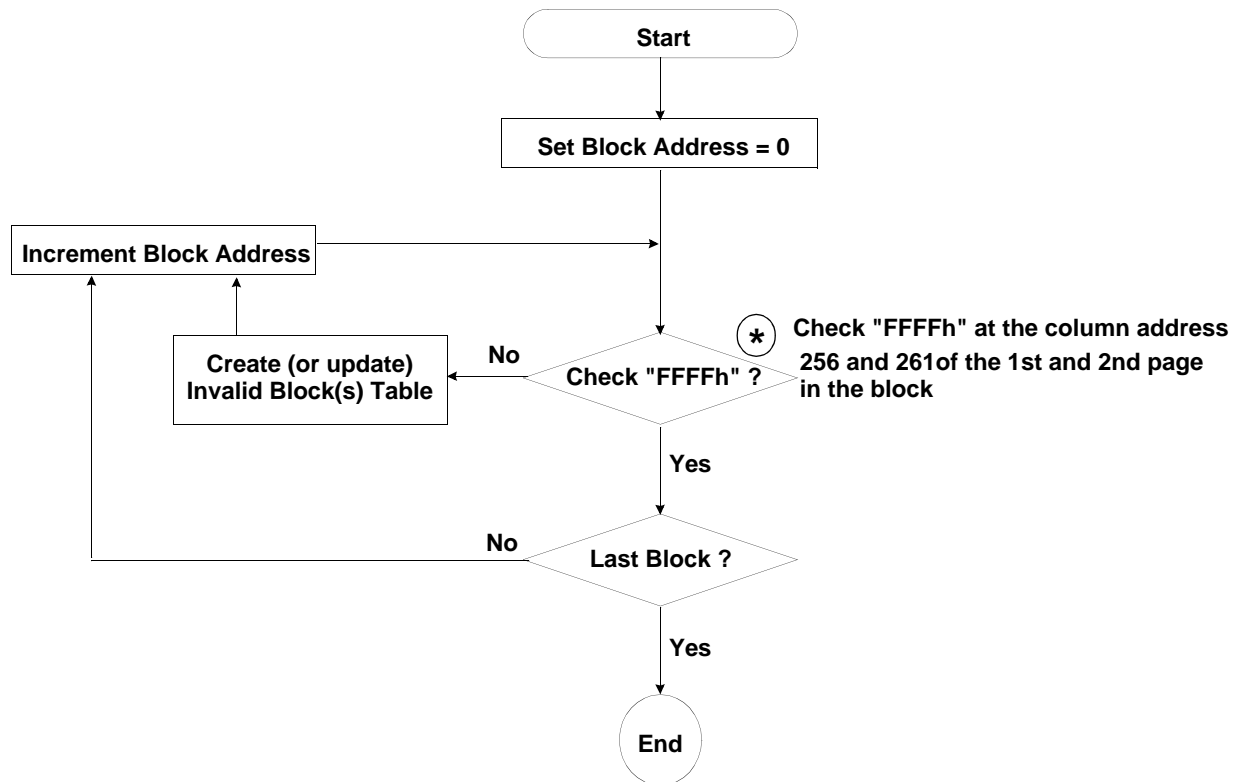

Figure 22. Flow chart to create invalid block table

## NAND Flash Technical Notes

### Error in write operation

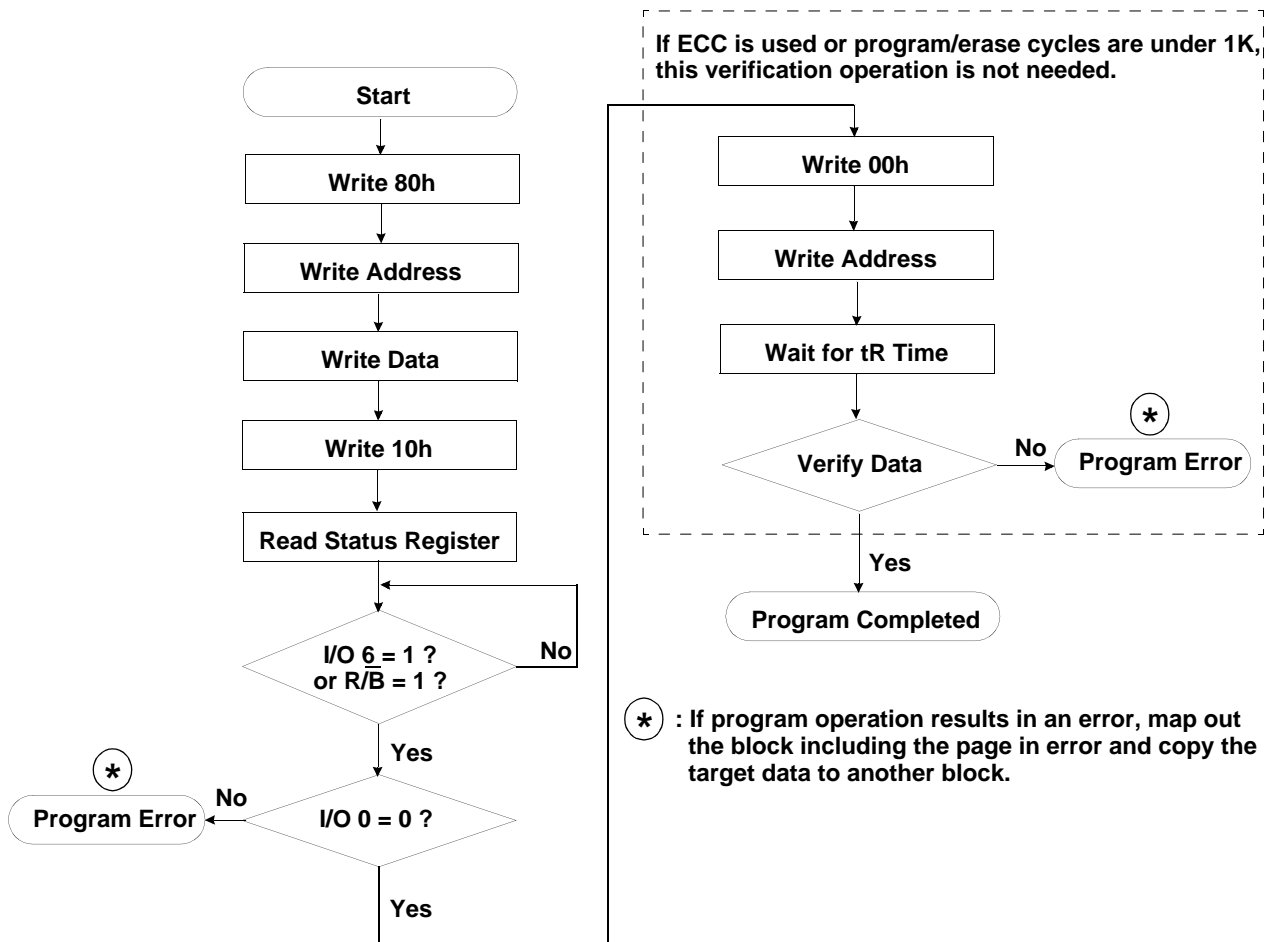

Over its life time, the additional invalid blocks may develop with NAND Flash memory. Refer to the qualification report for actual data. The following possible failure modes should be considered to implement a highly reliable system. In the case of status read failure after erase or program, block replacement should be done. Because program status fail during a page program does not affect the data of the other pages in the same block, block replacement can be executed with a page-sized buffer by finding an erased empty block and reprogramming the current target data and copying the rest of the replaced block. The said additional block failure rate does not include those reclaimed blocks.

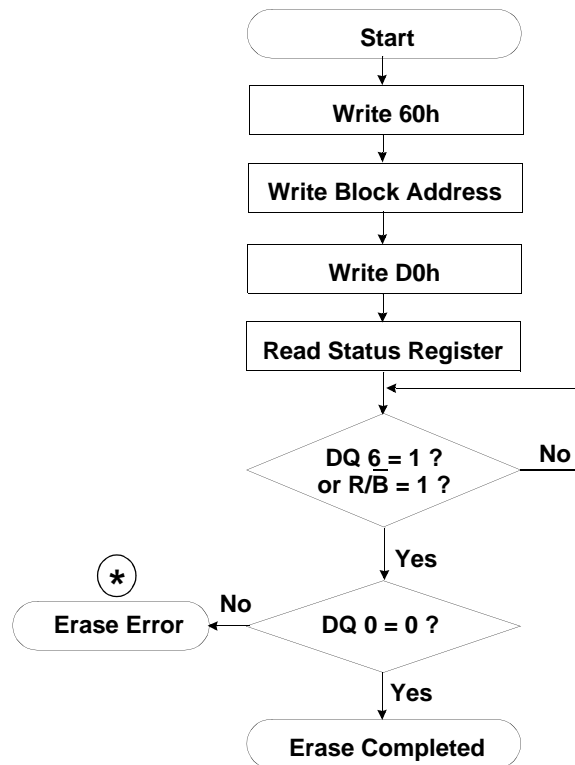

Failure Mode		Detection and Countermeasure sequence
Write	Erase Failure	Status Read after Erase --> Block Replacement
	Program Failure	Status Read after Program --> Block Replacement Read back ( Verify after Program ) --> Block Replacement
Read	Single Bit Failure (1)	Verify ECC -> ECC Correction (2)

**NOTE:** 1. If Program/Erase Cycles is under 1K, Single Bit Failure do not occur. Therefore there is no need to provide ECC.

2. ECC -> Error Correction Code -> Hamming Code etc.  
Example) 1bit error correction and 2 bit error detection

**Figure 24. Flash Program Flow Chart**

**NAND Flash Technical Notes****Figure 24. Flash Erase Flow Chart**

\* : If erase operation results in an error, map out the failing block and replace it with another block.

**Figure 25. Block Replacement**

\* Step1

When an error happens in the nth page of the Block 'A' during erase or program operation.

\* Step2

Copy the nth page data of the Block 'A' in the buffer memory to the nth page of another free block. (Block 'B')

\* Step3

Then, Copy the 1st ~ (n-1)th data to the same location of the Block 'B'.

\* Step4

Do not further erase Block 'A' by creating a 'invalid Block' table or other appropriate scheme.

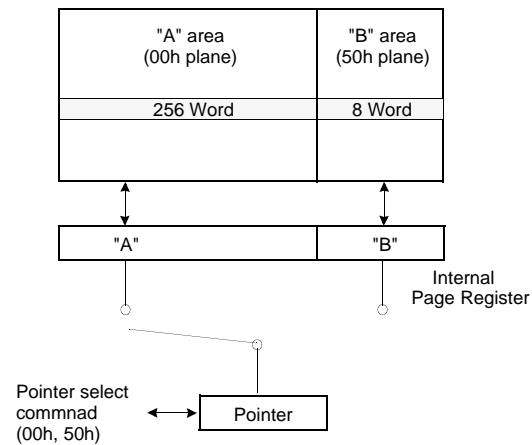

## NAND Flash Technical Notes

### Pointer Operation of NAND Flash

Samsung NAND Flash(x16) has two address pointer commands as a substitute for the two most significant column addresses. '00h' command sets the pointer to 'A' area(0~255word), and '50h' command sets the pointer to 'B' area(256~263word). With these commands, the starting column address can be set to any of a whole page(0~263word). '00h' or '50h' is sustained until another address pointer command is inputted. To program data starting from 'A' or 'B' area, '00h' or '50h' command must be inputted before '80h' command is written. A complete read operation prior to '80h' command is not necessary.

**Table 18. Destination of the pointer**

Command	Pointer position	Area
00h	0 ~ 255 word	main array(A)
50h	256 ~ 263 word	spare array(B)

**Figure 26. Block Diagram of Pointer Operation**

#### (1) Command input sequence for programming 'A' area

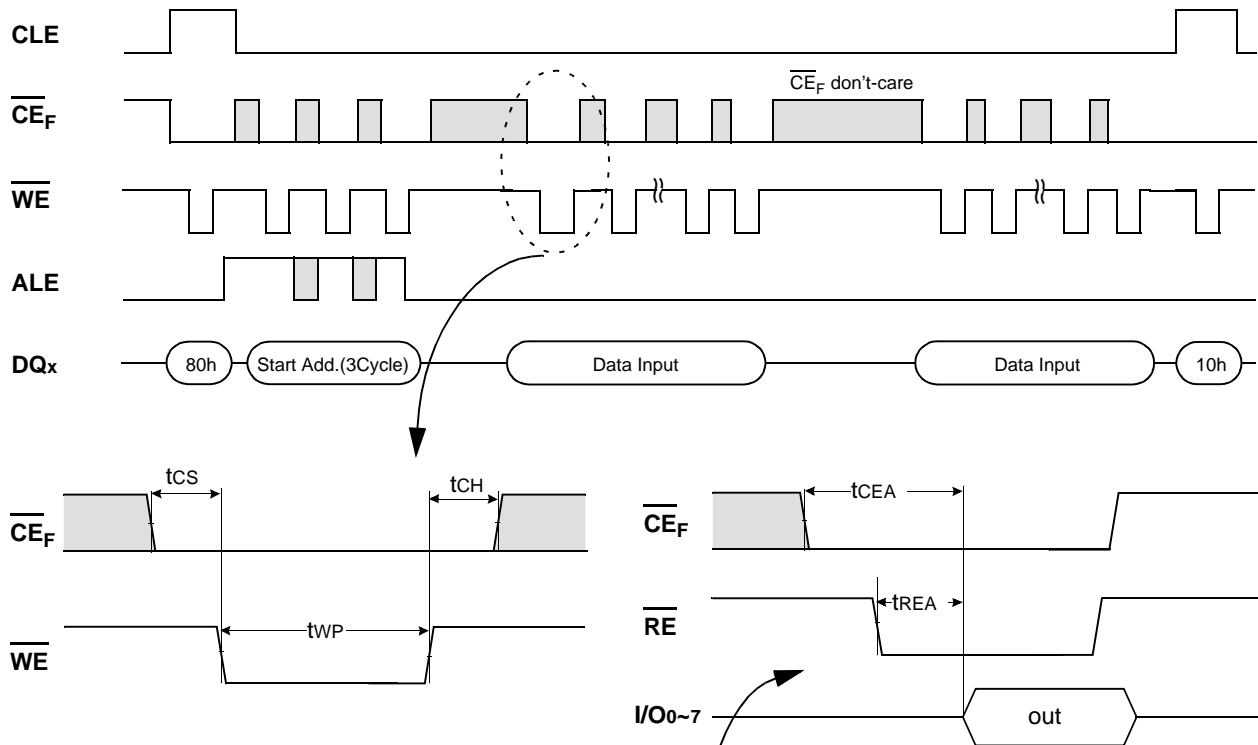

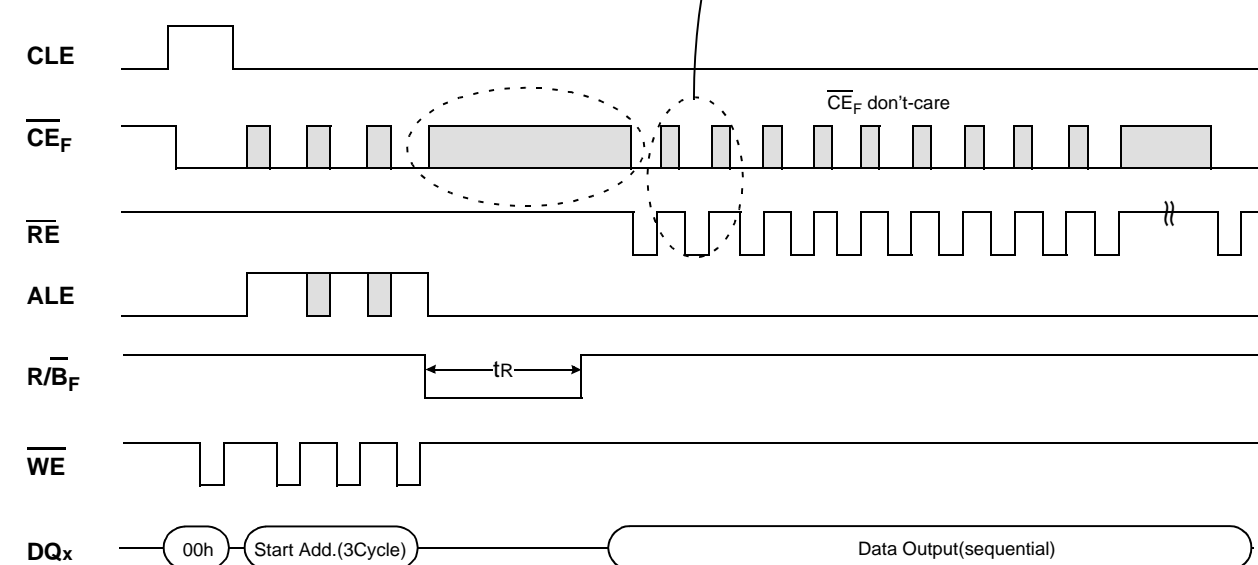

#### (2) Command input sequence for programming 'B' area

**NAND Flash Technical Notes****System Interface Using  $\overline{CE}_F$  don't-care.**

For an easier system interface,  $\overline{CE}_F$  may be inactive during data-loading or sequential data-reading as shown below. The internal 264word page registers are utilized as separate buffers for this operation and the system design gets more flexible. In addition, for voice or audio applications which use slow cycle time on the order of u-seconds, de-activating  $\overline{CE}_F$  during the data-loading and reading would provide significant saving in power consumption.

**Figure 27. Program Operation with  $\overline{CE}_F$  don't-care.****Figure 28. Read Operation with  $\overline{CE}_F$  don't-care.**

## ABSOLUTE MAXIMUM RATINGS

Parameter	Symbol	Rating	Unit
Voltage on any pin relative to Vss	Vcc	$V_{CCR}, V_{CCF}, V_{CCU}, V_{CCQU}$	-0.2 to Vcc+0.3
	RESET	VIN	-0.2 to 12.5V
	WP/ACC		-0.2 to 12.5V
	Other Balls		-0.2 to 3.6V
Temperature Under Bias	TBIAS	-40 to + 125	°C
Storage Temperature	TSTG	-65 to + 150	
Operating Temperature	TA	-25 to + 85	

## NOTE:

1. Minimum DC voltage is -0.2V on input/output balls. During transitions, this level may undershoot to -1.0V for periods <20ns.  
Maximum DC voltage on input/output balls is Vcc+0.3V which, during transitions, may overshoot to Vcc+1.0V for periods <20ns.
2. Minimum DC voltage is -0.2V on Reset and WP/ACC balls. During transitions, this level may undershoot to -1.0V for periods <20ns.  
Maximum DC voltage on on Reset and WP/ACC balls is 12.5V which, during transitions, may overshoot to 14.0V for periods <20ns.
3. Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to the conditions as detailed in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

## RECOMMENDED OPERATING CONDITIONS

(Voltage reference to Vss, TA=-25 to 85°C)

Parameter	Symbol	Min	Typ.	Max	Unit
Supply Voltage	$V_{CCR}, V_{CCF}, V_{CCU}, V_{CCQU}$	2.7	2.9	3.1	V
Supply Voltage	Vss	0	0	0	V

## DC AND OPERATING CHARACTERISTICS (Recommended operating conditions otherwise noted.)

Parameter	Symbol	Test Conditions	Min	Max	Unit
Input LeakAge Current	ILI	VIN=Vss to Vcc, Vcc=VCCmax	-10	10	μA
Output LeakAge Current	ILO	VOUT=Vss to Vcc, Vcc=VCCmax, OE=VIH	-10	10	μA
Input Low Voltage Level	VIL		-0.3	0.5	V
Input High Voltage Level	VIH		2.2	Vcc+0.3	
Output Low Voltage Level	VOL	IOL= 2.1mA, Vcc = VCCmin	-	0.4	
Output High Voltage Level	VOH	IOH= -1.0mA, Vcc = VCCmin	2.3	-

	Deep Power Down	ISBD	$\overline{ZZ} \leq 0.2V$ , Other input =0~ $V_{CCQ_U}$	-	5	10	$\mu A$	

## NOTES:

1. The Icc current listed includes both the DC operating current and the frequency dependent component(at 5 MHz).

The read current is typically 14 mA (@  $V_{CCR}=2.9V$ ,  $\overline{OE}$  at  $V_{IH}$ .)

2. Icc active during Internal Routine(program or erase) is in progress.

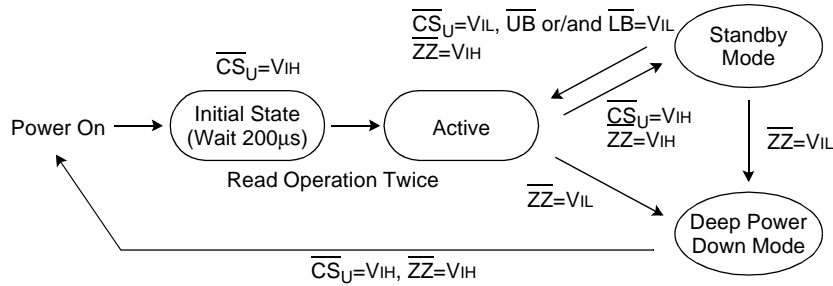

3. Icc active during Read while Write is in progress.

4. The high voltage (  $V_{HH}$  or  $V_{ID}$  ) must be used in the range of  $V_{CCR}=2.9V \pm 0.2V$

5. Not 100% tested.

6. Typical values are measured at  $V_{CC}=2.9V$ ,  $T_a=25^\circ C$ , not 100% tested.

## Standby Mode State Machines(UtRAM)

## Standby Mode Characteristic(UtRAM)

Power Mode	Memory Cell Data	Standby Current(μA)	Wait Time(μs)
Standby	Valid	100	0
Deep Power Down	Invalid	10	200

CAPACITANCE ( $T_A = 25^\circ\text{C}$ ,  $V_{CC} = 2.9\text{V}$ ,  $f = 1.0\text{MHz}$ )

Item	Symbol	Test Condition	Min	Max	Unit
Input Capacitance	$C_{IN}$	$V_{IN}=0\text{V}$	-	28	pF
Input/Output Capacitance	$C_{IO}$	$V_{IO}=0\text{V}$	-	30	pF

**NOTE:** Capacitance is periodically sampled and not 100% tested.

## VALID BLOCK OF NAND FLASH MEMORY

Parameter	Symbol	Min	Typ.	Max	Unit
Valid Block Number	NvB	1004	-	1024	Blocks

**NOTE:**

- The NAND Flash memory may include invalid blocks when first shipped. Additional invalid blocks may develop while being used. The number of valid blocks is presented with both cases of invalid blocks considered. Invalid blocks are defined as blocks that contain one or more bad bits.

**Do not try to access these invalid blocks for program and erase.**

Refer to the attached technical notes for a appropriate management of invalid blocks.

- The 1st block, which is placed on 00h block address, is fully guaranteed to be a valid block, does not require Error Correction.

## AC TEST CONDITION

Parameter	Value
Input Pulse Levels	0V to $V_{CC}$
Input Rise and Fall Times	5ns
Input and Output Timing Levels	$V_{CC}/2$ or $V_{CC}Q_U/2$
Output Load	$C_L = 30\text{pF}$

**NOTE:** AC test inputs are driven at  $V_{CC_R}$ ,  $V_{CC_F}$  or  $V_{CC_U}$  for a logic "1" and 0V for a logic "0". Input timing begins, and output timing ends, at  $V_{CC_R}/2$ ,  $V_{CC_F}/2$  or  $V_{CC_U}/2$ . Input rise and fall times (10% - 90%) < 5ns. Worst case speed condition are when  $V_{CC_R} = V_{CC_{Rmin}}$ ,  $V_{CC_F} = V_{CC_{Fmin}}$  or  $V_{CC_U} = V_{CC_{Umin}}$ .

## **ERASE AND PROGRAM PERFORMANCE**

Parameter		Limits			Unit	Comments
		Min	Typ	Max		
Block Erase Time		-	0.7	15	sec	Excludes 00H programming prior to erasure
Chip Erase Time		-	98	-	sec	
Word Programming Time		-	14	330	μs	Excludes system-level overhead
Byte Programming Time		-	9	210	μs	Excludes system-level overhead
Accelerated Byte/Word Program Time	Word Mode	-	9	210	μs	Excludes system-level overhead
	Byte Mode	-	7	150	μs	Excludes system-level overhead
Chip Programming Time	Word Mode	-	59	177	sec	Excludes system-level overhead
	Byte Mode	-	75	225	sec	
Erase/Program Endurance		100,000	-	-	cycles	Minimum 100,000 cycles guaranteed

**NOTES:** 1. 25 °C, V<sub>CC</sub><sub>R</sub> = 2.9V 100,000 cycles, typical pattern.  
2. System-level overhead is defined as the time required to execute the four bus cycle command necessary to program each byte. In the preprogramming step of the Internal Erase Routine, all bytes are programmed to 00H before erasure.

# NAND Flash Command Latch Cycle

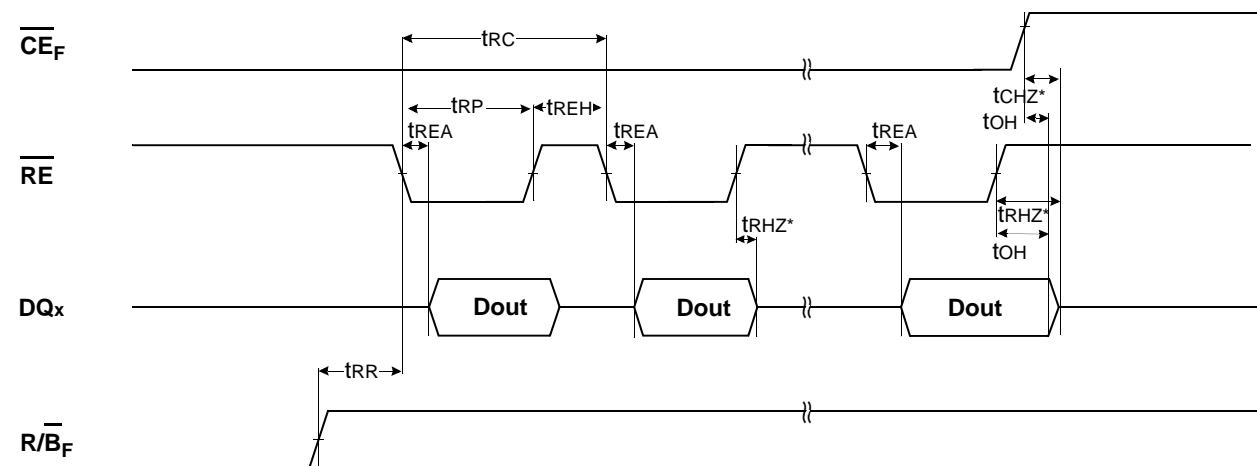

# NAND Flash Address Latch Cycle

NAND Flash Input Data Latch Cycle

NAND Flash Sequential Out Cycle after Read (CLE=L,  $\overline{WE}$ =H, ALE=L)

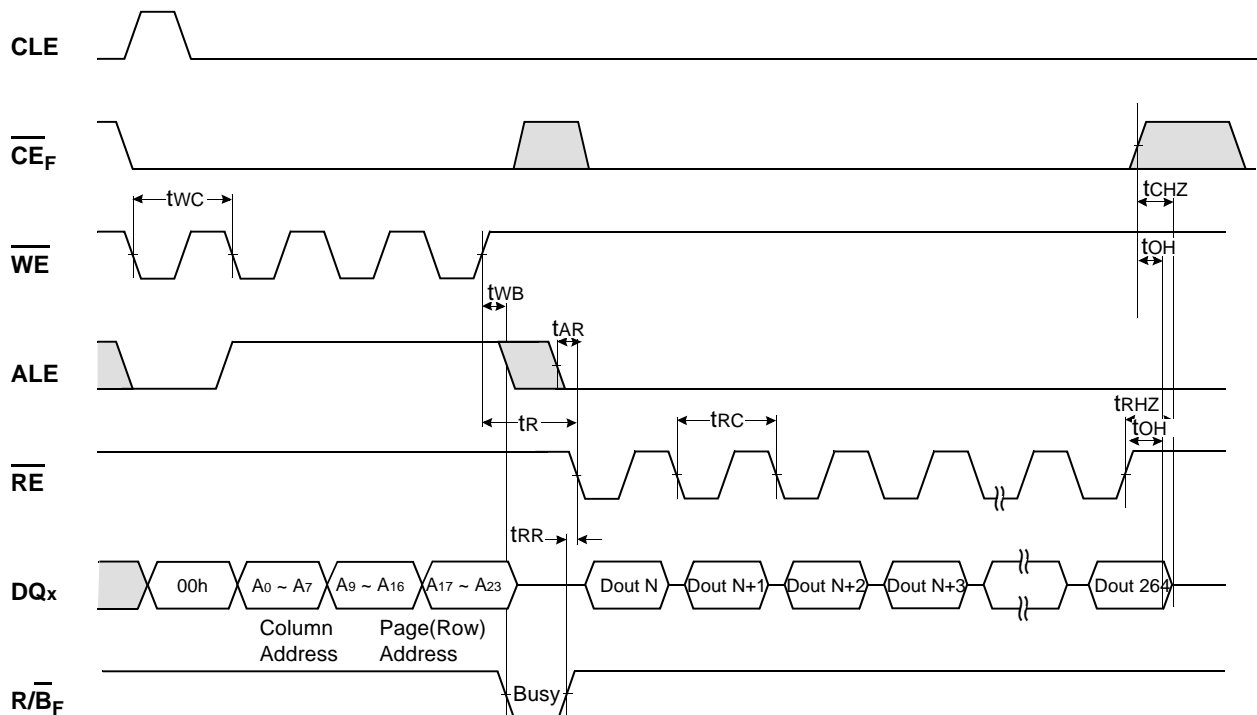

**NOTES :** Transition is measured  $\pm 200\text{mV}$  from steady state voltage with load.  
This parameter is sampled and not 100% tested.

# NAND Flash Status Read Cycle

# NAND FLASH READ1 OPERATION(READ ONE PAGE)

The timing diagram illustrates the sequence of operations for the 74VHC163 32-bit counter. The signals shown are CLE, CE\_F, WE, ALE, RE, DQx, and R/B\_F. The diagram shows the sequence of operations: address loading (A0-A7, A9-A16, A17-A23) and data output (Dout 256+M). Key timing parameters are labeled: tR (Read delay), tWB (Write delay), tAR (Address delay), and tRR (Read delay). A diagram at the bottom shows the selected row in the 256x8 memory array.

The timing diagram for the 28C64 EPROM shows the following signals and their waveforms:

- CLE**: Chip Latch Enable, active-low pulse.
- $\overline{\text{CE}}_{\text{F}}$** : Flash Chip Enable, active-low pulse.
- $\overline{\text{WE}}$** : Write Enable, active-low signal with multiple pulses. The width of each pulse is  $t_{\text{WC}}$ .
- ALE**: Address Latch Enable, active-low pulse.
- $\overline{\text{RE}}$** : Read Enable, active-low signal.
- DQ<sub>x</sub>**: Data/Address/Status bus. The sequence of operations is:
  - Sequential Data Input Command (80h)
  - Column Address (A0 ~ A7)
  - Page(Row) Address (A9 ~ A16, A17 ~ A23)
  - 1 up to 264 Word Data Serial Input (Din N, Din N+1, ..., Din 264)
  - Program Command (10h)
  - Read Status Command (70h)
  - DQ<sub>0</sub> output
- $\text{R}/\overline{\text{B}}_{\text{F}}$** : Read/Byte Flash Enable, active-low signal.

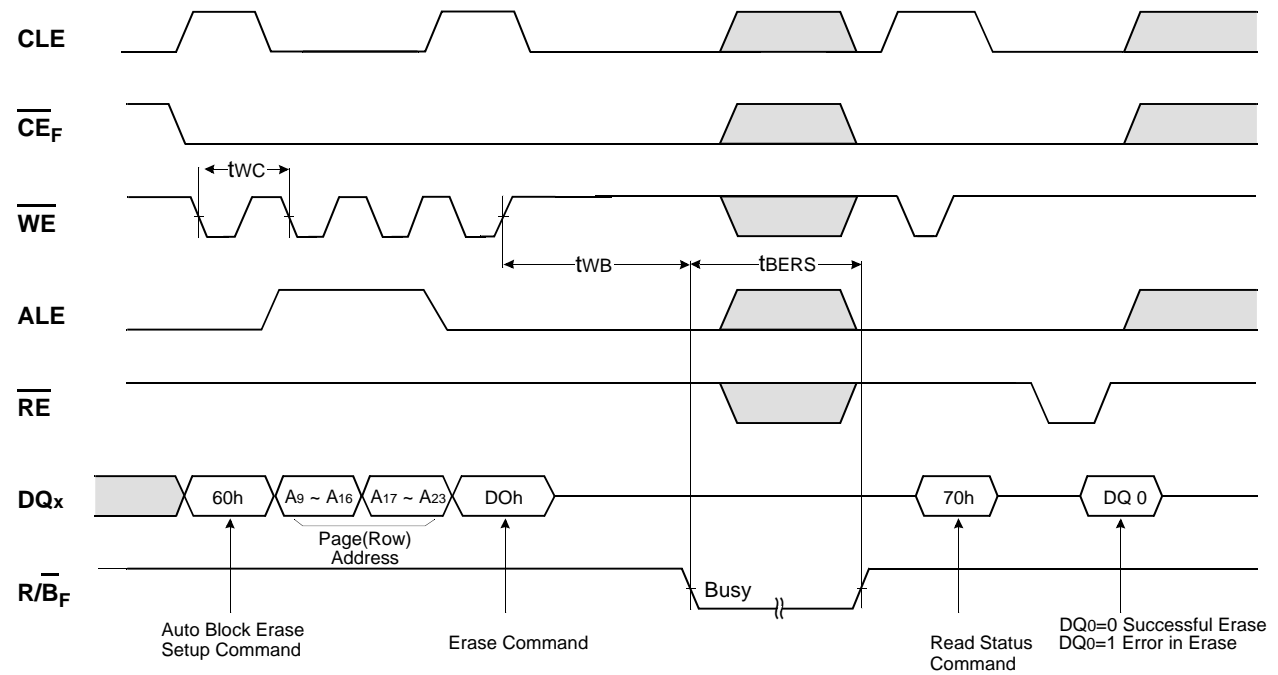

Key timing parameters are indicated:

- $t_{\text{WC}}$ : Write Enable pulse width.
- $t_{\text{WB}}$ : Write Burst time.
- $t_{\text{PROG}}$ : Programming time.

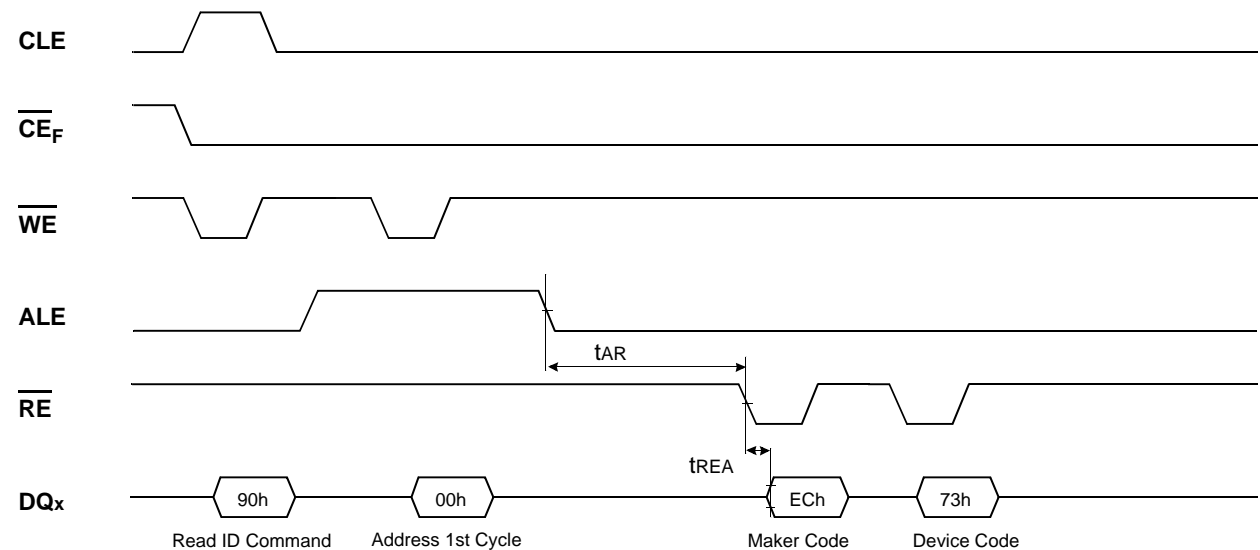

Legend for DQ<sub>0</sub> status:

- DQ<sub>0</sub>=0 Successful Program
- DQ<sub>0</sub>=1 Error in Program

1. The limitation in continuous write operation is up to 50 times. If you want to write continuously over 50 times, please refer to the technical note.

U<sub>t</sub>RAM TIMING DIAGRAMSTIMING WAVEFORM OF READ CYCLE(1)(Address Controlled,  $\overline{CS}_U = \overline{OE} = V_{IL}$ ,  $\overline{ZZ} = \overline{WE} = V_{IH}$ ,  $\overline{UB}$  or/and  $\overline{LB} = V_{IL}$ )TIMING WAVEFORM OF READ CYCLE(2)( $\overline{ZZ} = \overline{WE} = V_{IH}$ )

## (READ CYCLE)

1.  $t_{HZ}$  and  $t_{OHZ}$  are defined as the time at which the outputs achieve the open circuit conditions and are not referenced to output voltage levels.
2. At any given temperature and voltage condition,  $t_{HZ}(\text{Max.})$  is less than  $t_{LZ}(\text{Min.})$  both for a given device and from device to device interconnection.
3. The minimum read cycle( $t_{RC}$ ) is determined later one of the  $t_{RC1}$  and  $t_{RC2}$ .
4.  $t_{OE}(\text{max})$  is met only when  $\overline{OE}$  becomes enable after  $t_{AA}(\text{max})$ .

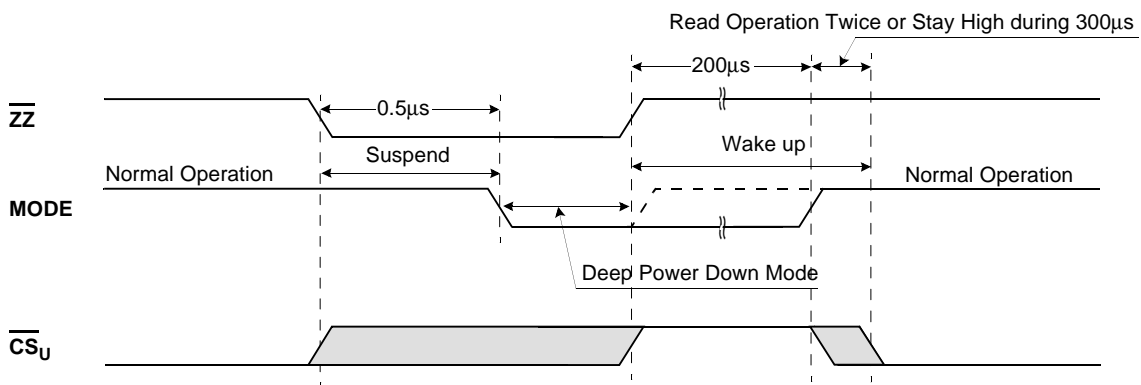

TIMING WAVEFORM OF WRITE CYCLE(1) ( $\overline{WE}$  Controlled,  $\overline{ZZ}=V_{IH}$ )TIMING WAVEFORM OF WRITE CYCLE(2) ( $\overline{CS}_U$  Controlled,  $\overline{ZZ}=V_{IH}$ )

TIMING WAVEFORM OF WRITE CYCLE(3)( $\overline{UB}$ ,  $\overline{LB}$  Controlled,  $\overline{ZZ}=V_{IH}$ )

## (WRITE CYCLE)

1. A write occurs during the overlap( $t_{WP}$ ) of low  $\overline{CS}_U$  and low  $\overline{WE}$ . A write begins when  $\overline{CS}_U$  goes low and  $\overline{WE}$  goes low with asserting  $\overline{UB}$  or  $\overline{LB}$  for single byte operation or simultaneously asserting  $\overline{UB}$  and  $\overline{LB}$  for double byte operation. A write ends at the earliest transition when  $\overline{CS}_U$  goes high and  $\overline{WE}$  goes high. The  $t_{WP}$  is measured from the beginning of write to the end of write.
2.  $t_{CW}$  is measured from the  $\overline{CS}_U$  going low to the end of write.
3.  $t_{AS}$  is measured from the address valid to the beginning of write.
4.  $t_{WR}$  is measured from the end of write to the address change.  $t_{WR}$  applied in case a write ends as  $\overline{CS}_U$  or  $\overline{WE}$  going high.

## TIMING WAVEFORM OF DEEP POWER DOWN MODE

## (DEEP POWER DOWN MODE)

1. When you toggle  $\overline{ZZ}$  pin low, the device gets into the Deep Power Down mode after 0.5μs suspend period.
2. To return to normal operation, the device needs Wake Up period.
3. Wake Up sequence is just the same as Power up sequences.

## TIMING WAVEFORM OF POWER UP(1)

## (POWER UP(1))

1. After  $V_{CCU}$  reaches  $V_{CCU}(\text{Min.})$  following power application, wait 200  $\mu\text{s}$  with  $\overline{CS_U}$  high and then toggle  $\overline{CS_U}$  low and commit Read Operation at least twice. Then you get into the normal operation.
2. Read operation should be executed by toggling  $\overline{CS_U}$  pin low.
3. The read operation must satisfy the specified  $t_{RC}$ .
4.  $\overline{ZZ}$  pin should be kept high during whole power up sequence.

## TIMING WAVEFORM OF POWER UP(2)(No Dummy Cycle)

## (POWER UP(2))

1. After  $V_{CCU}$  reaches  $V_{CCU}(\text{Min.})$  following power application, wait 200  $\mu\text{s}$  and wait another 300  $\mu\text{s}$  with  $\overline{CS_U}$  high if you don't want to commit dummy read cycle. After total 500  $\mu\text{s}$  wait, toggle  $\overline{CS_U}$  low, then you get into the normal mode.
2.  $\overline{ZZ}$  pin should be kept high during whole power up sequence.

## TECHNICAL NOTE

## U $\bar{t}$ RAM USAGE AND TIMING

### INTRODUCTION

U $\bar{t}$ RAM is based on single-transistor DRAM cells. As with any other DRAM, the data in these cells must be periodically refreshed to prevent data loss. What makes the U $\bar{t}$ RAM unique is that it offers a true SRAM style interface that hides all refresh operations from the memory controller.

### START WITH A DRAM TECHNOLOGY

The key point of U $\bar{t}$ RAM is its high speed and low power. This high speed comes from the use of many small blocks such as 32Kbits each to create U $\bar{t}$ RAM arrays. The small blocks have short word lines thus with little capacitance eliminating a major factor of operating current dissipation in conventional DRAM blocks.

Each independent macro-cell on a U $\bar{t}$ RAM device consists of a number of these blocks. Each chip has one or more macro.

The address decoding logic is also fast. U $\bar{t}$ RAM performs a complete read operation in every tRC, but U $\bar{t}$ RAM needs power up sequence like DRAM.

#### Power Up Sequence and Diagram

1. Apply power.
2. Maintain stable power for a minimum 200 $\mu$ s with  $\overline{CS_U}$ =high.
3. Issue read operation at least 2 times.

Figure 29.

Figure 30.

### DESIGN ACHIEVES SRAM SPECIFIC OPERATIONS

The U $\bar{t}$ RAM was designed to work just like an SRAM - without any waits or other overhead for precharging or refreshing its internal DRAM cells. SAMSUNG Electronics(SAMSUNG) hides these operations inside with advanced design technology - those are not to be seen from outside. Precharging takes place during every access, overlapped between the end of the cycle and the decoding portion of the next cycle.

Hiding refresh is more difficult. Every row in every block must be refreshed at least once during the refresh interval to prevent data loss. SAMSUNG provides an internal refresh controller for devices. When all accesses within refresh interval are directed to one macro-cell, as can happen in signal processing applications, a more sophisticated approach is required to hide refresh. The pseudo SRAM is sometimes used on these applications, which requires a memory controller that can hold off accesses when a refresh operation is needed. SAMSUNG's unique qualitative advantage over these parts(in addition to quantitative improvements in access speed and power consumption) is that the U $\bar{t}$ RAM never need to hold off accesses, and indeed it has no hold off signal. The circuitry that gives SAMSUNG this advantage is fairly simple but has not previously been disclosed.

### AVOID TIMING

Following figures show you an abnormal timing which is not supported on U $\bar{t}$ RAM and its solution.

If your system has a timing which sustains invalid states over 4 $\mu$ s at read mode like Figure 29, there are some guide lines for proper operation of U $\bar{t}$ RAM.

When your system has multiple invalid address signals shorter than tRC on the timing shown in Figure 1, U $\bar{t}$ RAM needs a normal read timing(tRC) during that cycle(Figure 30) or needs to toggle  $\overline{CS_U}$  once to 'high' for about 'tRC'(Figure 31).

Figure 31.

Write operation has similar restriction to Read operation. If your system has a timing which sustains invalid states over  $4\mu s$  at write mode and has continuous write signals with length of Min.  $t_{WC}$  over  $4\mu s$  like Figure 32, you must toggle  $\overline{WE}$  once to high

and make it stay high at least for  $t_{RC}$  every  $4\mu s$  or toggle  $\overline{CS}_U$  once to high for about  $t_{RC}$ .
