The S-8321/8322 Series is a CMOS PFM-control step-up switching regulator which mainly consists of a reference voltage source, an oscillation circuit, a power MOS FET, and a comparator. The new method PFM control circuit automatically switches the duty ratio according to load, offering products of low ripple over a wide range, high efficiency, high output current. A step-up switching regulator is constructed by externally connecting only a coil, a capacitor and a diode to the S-8321/8322 Series. This feature, along with its small package and low current consumption, makes the S-8321/8322 Series ideal for the power supply of portable equipment. A built-in protection circuit prevents damage to the IC by turning off the MOS FET when the voltage at CONT pin exceeds the limit during ON of the built-in MOS FET. For applications requiring a high output current, products used with an external transistor are also available in S-8322 Series.

#### ■ Features

- Low voltage operation: 0.9 V min. ( $I_{OUT} = 1 \text{ mA}$ )
- Low input current:
  - During operation:  $6.8 \mu\text{A}$  ( $V_{OUT} = 3 \text{ V}$ , no load, typ.)
  - During shutdown:  $0.5 \mu\text{A}$  (max.)
- Duty ratio: auto-switching PFM control circuit type
- External parts: coil, diode, and capacitor only
- Output voltage: accuracy of  $\pm 2.4\%$
- Shutdown function
- External transistor type is available (S-8322 Series)
- A Series : SOT-23-5 package
- B Series : SOT-23-3 package

### Selection Guide

#### 1. Name of the Product

#### 2. List of the Product

Products	S-8321A Series	S-8322A Series	S-8321B Series	S-8322B Series
Output voltage (V)				
2.5	S-8321AJMP-DNJ-T2	S-8322AJMP-DOJ-T2	_____	_____
2.7	S-8321ALMP-DNL-T2	_____	S-8321BLMP-DTL-T2	_____
3.0	S-8321AIMP-DNI-T2	S-8322AIMP-DOI-T2	S-8321BIMP-DTI-T2	S-8322BIMP-DUI-T2
3.3	S-8321AGMP-DNG-T2	S-8322AGMP-DOG-T2	S-8321BGMP-DTG-T2	_____
3.5	S-8321AFMP-DNF-T2	S-8322AFMP-DOF-T2	_____	_____
5.0	S-8321AAMP-DNA-T2	S-8322AAMP-DOA-T2	S-8321BAMP-DTA-T2	S-8322BAMP-DUA-T2

Consult our sales person for products with an output voltage other than specified above.

### Pin Assignment

(1) SOT-23-5  
Top view

- 1 ON / OFF
- 2 V<sub>OUT</sub>
- 3 NC
- 4 V<sub>SS</sub>
- 5 CONT / EXT

(2) SOT-23-3  
Top view

- 1 V<sub>SS</sub>
- 2 V<sub>OUT</sub>
- 3 CONT / EXT

Pin name	Functions
ON / OFF	Shutdown pin "H": normal operation (stepping up operation) "L": stop stepping up (circuit stop)
V <sub>OUT</sub>	Output voltage pin and IC power supply
V <sub>SS</sub>	GND
CONT	External inductor connection Note 1
EXT	External transistor connection Note 2

Note 1: S-8321 Series : Open drain output

Note 2: S-8322 Series: CMOS output

## Test Circuits

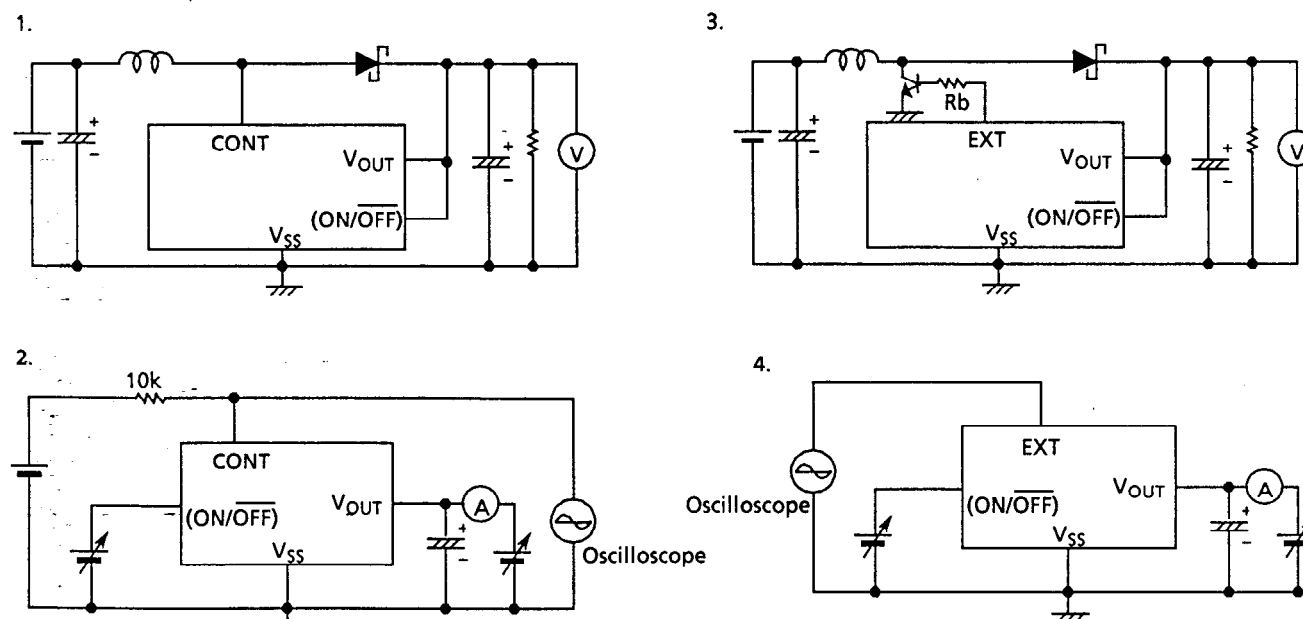

Figure 3

### ■ Operation

#### 1. Step-Up DC/DC Converter

The S-8321/8322 Series is a DC/DC converter using a pulse frequency modulation method (PFM) with a low current consumption. Especially in the region of 100 $\mu$ A output load current, a high-efficiency DC/DC converter is obtained.

In conventional fixed-duty type PFM DC/DC converters, pulses are skipped at low output load current, causing fluctuation in ripple frequency of the output voltage, with the result of increase in ripple voltage. The S-8321/8322 Series ensures load drive capacity in the region of large output load current by making duty ratio 75%, whereas in the region of small output load current the S-8321/8322 Series lowers the load drive capacity by automatically switching the duty ratio to 50% (It may range from 50% to less than 75% depending upon coil and load conditions.) and thereby reduces pulse skip. This controls drop in ripple frequency and limits the increase in ripple voltage.

Figure 4 and Figure 5 show ripple voltage vs. output current characteristic. For example in the S-8321 AIMP, at  $V_{IN} = 2.0$  V, a sudden change in ripple voltage around  $I_{OUT} = 40$  mA is seen in Figure 4. This means that if the load switches from large current to small current, ripple voltage does not decrease in conventional fixed-duty type converter, whereas ripple voltage significantly decreases in duty ratio automatic switching type PFM type converter.

Figure4

Figure5

Shutdown pin: Stops or starts step-up operation.

(A series only) Turning the shutdown pin low stops operation of all the internal circuits and reduces current consumption significantly. Do NOT use the shutdown pin in floating state because it has a structure shown in Figure 6 and is not pulled up or pulled down internally. Do NOT apply voltage of between 0.3 V and 0.75 V to the shutdown pin because applying such voltage increases the current consumption. If the shutdown pin is not used, connect it to VOUT pin.

The shutdown pin doesn't have hysteresis.

Shutdown pin	CR oscillation circuit	Output voltage
"H"	Operation	Fixed
"L"	Stop	$\approx V_{IN}^*$

\* Voltage obtained by extracting the voltage drop due to DC resistance of the inductor and the diode forward voltage from  $V_{IN}$ .

Figure 6

Figure 7

The following are basic equations [(1) through (7)] of the step-up switching regulator (see Figure 7).

Voltage at CONT pin the moment M1 is turned ON (current  $I_L$  flowing through L is zero):

$$V_A = V_S \quad \dots \quad (1)$$

( $V_S$ : Non-saturated voltage of M1)

The change in  $I_L$  over time:

$$\frac{dI_L}{dt} = \frac{V_L}{L} = \frac{V_{IN} - V_S}{L} \quad \dots \quad (2)$$

Integration of the above equation ( $I_L$ ):

$$I_L = \left( \frac{V_{IN} - V_S}{L} \right) \cdot t \quad \dots \quad (3)$$

$I_L$  flows when M1 is turned ON ( $t_{ON}$ ). The time of  $t_{ON}$  is determined by the oscillation frequency of the OSC.

The peak current ( $I_{PK}$ ) after M1 is turned ON ( $t_{ON}$ ):

$$I_{PK} = \left( \frac{V_{IN} - V_S}{L} \right) \cdot t_{ON} \quad \dots \quad (4)$$

The energy stored in L is represented with  $\frac{1}{2} L (I_{PK})^2$ .

When M1 is turned OFF ( $t_{OFF}$ ), the energy stored in L is transmitted through a diode to the output capacitor. Then reverse voltage ( $V_L$ ) is generated.

$$V_L = (V_{OUT} + V_D) - V_{IN} \quad \dots \quad (5)$$

( $V_D$ : Diode forward voltage)

The voltage at CONT pin rises only by the voltage corresponding to  $V_{OUT} + V_D$ .

The change in the current flowing through the diode into  $V_{OUT}$  during  $t_{OFF}$ :

$$\frac{dI_L}{dt} = \frac{V_L}{L} = \frac{V_{OUT} + V_D - V_{IN}}{L} \quad \dots \quad (6)$$

Integration of the above equation is as follows:

$$I_L = I_{PK} - \left( \frac{V_{OUT} + V_D - V_{IN}}{L} \right) \cdot t \quad \dots \quad (7)$$

During  $t_{ON}$ , the energy is stored in  $L$  and is not transmitted to  $V_{OUT}$ . When receiving output current ( $I_{OUT}$ ) from  $V_{OUT}$ , the energy of the capacitor ( $C_{OUT}$ ) is consumed. As a result, the pin voltage of  $C_{OUT}$  is reduced, and goes to the lowest level after  $M1$  is turned ON ( $t_{ON}$ ). When  $M1$  is turned OFF, the energy stored in  $L$  is transmitted through the diode to  $C_{OUT}$ , and the voltage of  $C_{OUT}$  rises drastically.  $V_{OUT}$  is a time function that indicates the maximum value (ripple voltage:  $V_{P-P}$ ) when the current flowing through the diode into  $V_{OUT}$  and load current ( $I_{OUT}$ ) match.

Next, the ripple voltage is found out as follows:

$I_{OUT}$  vs  $t_1$  (time) from when  $M1$  is turned ON ( $t_{ON}$ ) to when  $V_{OUT}$  reaches the maximum level:

$$I_{OUT} = I_{PK} - \left( \frac{V_{OUT} + V_D - V_{IN}}{L} \right) \cdot t_1 \quad \dots \quad (8)$$

$$\therefore t_1 = (I_{PK} - I_{OUT}) \left( \frac{L}{V_{OUT} + V_D - V_{IN}} \right) \quad \dots \quad (9)$$

When  $M1$  is turned OFF ( $t_{OFF}$ ),  $I_L = 0$  (when the energy of the inductor is completely transmitted). Based on equation (7),

$$\left( \frac{L}{V_{OUT} + V_D - V_{IN}} \right) = \frac{t_{OFF}}{I_{PK}} \quad \dots \quad (10)$$

When substituting equation (10) for equation (9),

$$t_1 = t_{OFF} - \left( \frac{I_{OUT}}{I_{PK}} \right) \cdot t_{OFF} \quad \dots \quad (11)$$

Electric charge  $\Delta Q_1$  which is charged in  $C_{OUT}$  during  $t_1$ :

$$\begin{aligned} \Delta Q_1 &= \int_0^{t_1} I_L dt = I_{PK} \cdot \int_0^{t_1} dt - \frac{V_{OUT} + V_D - V_{IN}}{L} \cdot \int_0^{t_1} t dt \\ &= I_{PK} \cdot t_1 - \frac{V_{OUT} + V_D - V_{IN}}{L} \cdot \frac{1}{2} t_1^2 \quad \dots \quad (12) \end{aligned}$$

When substituting equation (9) for equation (12):

$$\Delta Q_1 = I_{PK} - \frac{1}{2} (I_{PK} - I_{OUT}) \cdot t_1 = \frac{I_{PK} + I_{OUT}}{2} \cdot t_1 \quad \dots \quad (13)$$

A rise in voltage ( $V_{P-P}$ ) due to  $\Delta Q_1$ :

$$V_{P-P} = \frac{\Delta Q_1}{C_{OUT}} = \frac{1}{C_{OUT}} \cdot \left( \frac{I_{PK} + I_{OUT}}{2} \right) \cdot t_1 \quad \dots \quad (14)$$

When taking into consideration  $I_{OUT}$  to be consumed during  $t_1$  and ESR (Electric Series Resistance) of  $C_{OUT}$ , namely  $R_{ESR}$ :

$$V_{P-P} = \frac{\Delta Q_1}{C_{OUT}} = \frac{1}{C_{OUT}} \cdot \left( \frac{I_{PK} + I_{OUT}}{2} \right) \cdot t_1 + \left( \frac{I_{PK} + I_{OUT}}{2} \right) R_{ESR} - \frac{I_{OUT} \cdot t_1}{C_{OUT}} \quad \dots \quad (15)$$

When substituting equation (15) for equation (11):

$$V_{P-P} = \frac{(I_{PK} - I_{OUT})^2}{2I_{PK}} \cdot \frac{t_{OFF}}{C_{OUT}} + \left( \frac{I_{PK} + I_{OUT}}{2} \right) \cdot R_{ESR} \quad \dots \quad (16)$$

Therefore to reduce the ripple voltage, it is important that the capacitor connected to the output pin has a large capacity and a small ESR.

## ■ External Part Selection

### 1. Inductor

To minimize a loss due to inductor DC resistance, select an inductor with a smallest possible DC resistance (less than 1  $\Omega$ ). Set the inductance value around 22  $\mu\text{H}$  to 1 mH.

To make the average value of the output voltage ( $V_{\text{OUT}}$ ) constant, it is necessary to supply the energy corresponding to the output current ( $I_{\text{OUT}}$ ) from the inductor. The amount of charge required for  $I_{\text{OUT}}$  is  $I_{\text{OUT}} \times (t_{\text{ON}} + t_{\text{OFF}})$ . Because the inductor can supply the energy only during  $t_{\text{OFF}}$ , the charge is obtained by integrating equation (7) with  $0 \rightarrow t_{\text{OFF}}$ , namely,

$\frac{I_{\text{PK}}}{2} \cdot t_{\text{OFF}}$ . Thus,

$$\frac{I_{\text{PK}}}{2} \cdot t_{\text{OFF}} = I_{\text{OUT}} \times (t_{\text{ON}} + t_{\text{OFF}}) \quad \dots\dots\dots (17)$$

$$\therefore I_{\text{PK}} = 2 \cdot \frac{t_{\text{ON}} + t_{\text{OFF}}}{t_{\text{OFF}}} \cdot I_{\text{OUT}} \quad \dots\dots\dots (18)$$

When the duty ratio of the OSC is 75%,  $I_{\text{PK}} = 8 \cdot I_{\text{OUT}}$ . Therefore, an  $I_{\text{PK}}$  current which is eight times  $I_{\text{OUT}}$  flows into transistor M1.

The S-8321 Series includes a switching current control circuit which monitors the current flowing into the CONT pin by the voltage (CONT control voltage) and controls the current. This circuit prevents the IC destruction due to excess current.

If an inductor with a large value of L is selected, both  $I_{\text{PK}}$  and  $I_{\text{OUT}}$  decrease. Since the energy stored in the inductor is equal to  $\frac{1}{2}L \cdot (I_{\text{PK}})^2$ , the energy decreases because  $I_{\text{PK}}$  decreases in steps of squares offsetting the increase of L. As a result, stepping up at low voltage becomes difficult and the minimum operating input voltage becomes high. However, DC resistance loss in L and the M1 transistor becomes small because of decreased  $I_{\text{PK}}$ , and inductance efficiency improves.

On the other hand, if an inductor with a smaller value of L is selected, both  $I_{\text{PK}}$  and  $I_{\text{OUT}}$  increase. Accordingly the minimum operating input voltage becomes low but the inductance efficiency deteriorates.

[ CAUTION ] An excessively large  $I_{\text{PK}}$  may cause magnetic saturation for some core materials, leading to the destruction of the IC. Use a core of material satisfies  $I_{\text{sat}} > I_{\text{PK}}$  ( $I_{\text{sat}}$ : level of current that causes magnetic saturation).

### 2. Diode

Use an external diode that meets the following requirements:

- Low forward voltage ( $V_F < 0.3\text{V}$ )
- High switching speed (500 ns max.)
- Reverse voltage:  $V_{\text{OUT}} + V_F$  or more
- Rated current:  $I_{\text{PK}}$  or more

### 3. Capacitors ( $C_{\text{IN}}$ , $C_{\text{OUT}}$ )

A capacitor at the input side ( $C_{\text{IN}}$ ) improves the efficiency by reducing the power impedance and stabilizing the input current. Select a  $C_{\text{IN}}$  value according to the impedance of the power supply used. The capacitor value should be around 10  $\mu\text{F}$ .

A capacitor at the output side ( $C_{\text{OUT}}$ ) is used for smoothing the ripple voltage. Therefore select a capacitor with a small ESR (Electric Series Resistance) and a large capacitance. The capacitor value should be 10  $\mu\text{F}$  min. A tantalum electrolytic capacitor and an organic semiconductor capacitor are especially recommended because of their superior low-temperature characteristic and leakage current characteristic.

#### 4. External transistor (S-8322 Series)

For the S-8322 Series, connecting an external transistor increases the output current. A bipolar transistor or an enhancement MOS FET transistor can be used as external transistor.

##### 4.1. Bipolar transistor

A circuit example using a bipolar transistor (NPN), Sanyo 2SD1628G is shown in Figure 11. The  $R_b$  value determines the driving capacity to increase the output current using a bipolar transistor. A peripheral circuit example of the transistor is shown in Figure 8 to determine the  $R_b$  value.

**Figure 8 External transistor peripheral circuit**

Stepping up capacity characteristics does not show much difference with the  $R_b$  value between 100 and 750  $\Omega$ , but 300  $\Omega$  is recommended. The current flows pulsating and there is voltage drop due to wiring resistance in an actual circuit, therefore optimum  $R_b$  value should be determined by experiment.

A speed-up capacitor connected in parallel with  $R_b$  resistance as shown in Figure 8 decreases the switching loss and improves the efficiency.

##### 4.2. Enhancement MOS FET type

Figure 9 is a circuit example using NEC 2SK1959 MOS FET transistor (N-channel).

For a MOS FET, an N-channel power MOS FET should be used. In particular the EXT pin of the S-8322 can drive a MOS FET with a gate capacity of around 1000 pF. Because the gate voltage and current of the external power MOS FET are supplied from the stepped out output voltage  $V_{OUT}$ , the MOS FET is driven more effectively.

Since the ON resistor of the MOS FET might affect the output amperage as well as the efficiency, the threshold voltage should be low. When the output voltage is as low as 2.5 V the same as in the S-8322AJMP, the circuit operates only when the MOS FET has the threshold voltage lower than 2.5 V.

(2) 8322 Series

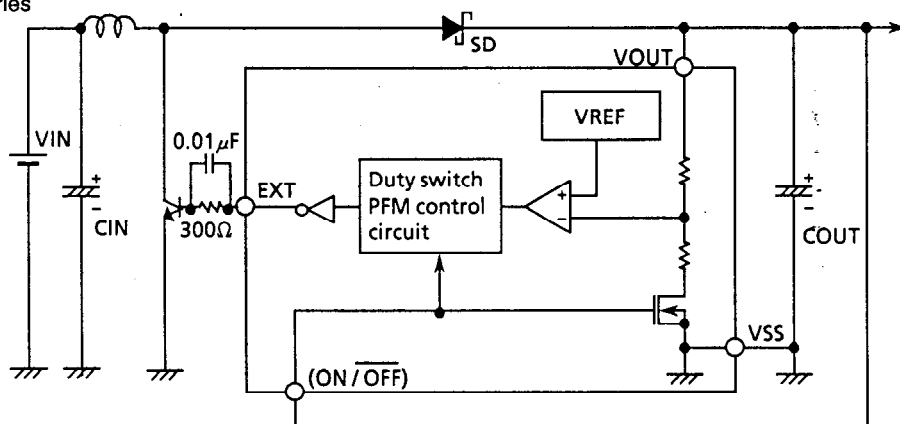

Figure 11

## Precautions

- Mount external capacitors, a diode, and a coil as near as possible to the IC.
- Ripple voltage and spike noise occur in switching regulators. Because they largely depend on the coil and the capacitor used, check them using an actually mounted model.
- Seiko Instruments shall not be responsible for any patent infringement by products including S-8321/8322 Series in connection with the method of using S-8321/8322 Series in such products, the specification of such products, or the country of destination thereof.
- Make sure dissipation of the switching transistor (especially at a high temperatures) does not exceed the allowable power dissipation of the package.

Figure 12 Power dissipation of the package (before mounting)

- When the impedance of the power supply is high, the shutdown pin is turned from "L" to "H" or VIN is connected to the power supply, note that the power supply voltage drops temporarily because the rush current flows into the power supply.
