

High Efficiency Charge Pump Regulator for White LEDs

FEATURES

- Ideal For White LED Driver
- Low Profile, Inductorless Regulator
- X1.5 and X2 Modes for Highest Efficiency
- +2.7V to +5.5V Input Voltage Range
- Fast Turn-On Time, 175 μ S
- 1mA Quiescent Current
- <1.5 μ A Shutdown Current
- Built-in 600kHz Oscillator
- Programmable Output Current or Voltage
- PWM Dimming Control with Enable Pin
- Shutdown to Disconnect Output from Input
- Soft Start to Eliminate In-Rush Current
- Industry Standard 10-pin MSOP Package and Small 10-pin DFN Package

Now Available in Lead Free Packaging

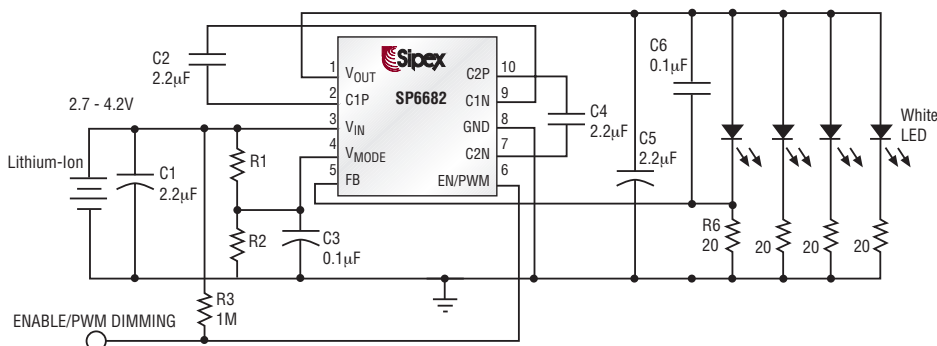

APPLICATIONS

- Next Generation Mobile Phones
- PDAs
- 3.3V to 5.0V Conversion
- Digital Still Cameras
- Digital Camcorders
- Palmtop Computers
- Color LCD Modules

DESCRIPTION

The SP6682 is a current regulated charge pump ideal for converting a Li-Ion battery input for driving white LED used in backlighting color displays. The charge pump automatically switches between X1.5 and X2 modes based on the input voltage, providing improved efficiency over traditional methods using charge pump doubler followed by LDO. This input voltage threshold can be externally programmed for optimized efficiency at specific output voltages and currents. The SP6682 operates with an internal 600kHz clock, enabling the use of small external components. Output current or voltage can be accurately regulated by modulating the switcher between the charge pump and output capacitor. In shutdown mode, the IC disconnects the output from the input and draws less than 1.5 μ A current. The SP6682 is offered in a 10-pin MSOP package, and a small 10-Pin DFN Package.

TYPICAL APPLICATION SCHEMATIC

ABSOLUTE MAXIMUM RATINGS

V_{IN} , V_{MODE} , V_{OUT} and EN/PWM -0.3V to 6V
 $V_{IN} - V_{OUT}$ 0.7V
 Output Current (I_{OUT}) 120mA
 Power Dissipation per Package - 10-pin MSOP
 (derate 8.84mW/°C above +70°C) 720mW
 Junction Temperature +125°C
 Storage Temperature -65°C to +150°C
 ESD Rating. 2kV HBM

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

ELECTRICAL CHARACTERISTICS

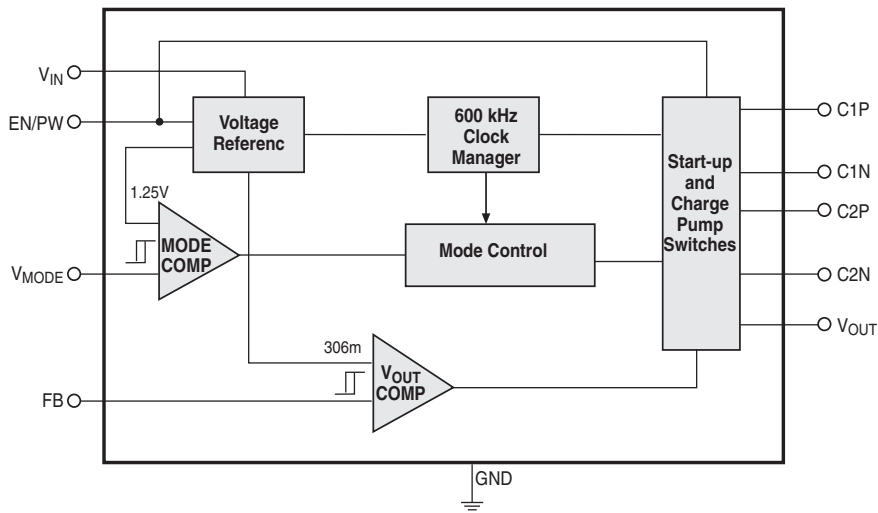

Unless otherwise specified: $V_{IN} = +2.7V$ to $+5.0V$, $C1=C2=C4=C5=2.2\mu F$ (ceramic, ESR=0.03Ω), $C3=0.1\mu F$ (ceramic) and $T_{AMB} = -40^{\circ}C$ to $+85^{\circ}C$ unless otherwise noted.

| PARAMETER | MIN | TYP | MAX | UNITS | CONDITIONS |
|--|-------|-------|-------|------------------|---|
| Input Voltage | 2.7 | | 5.5 | V | |
| Quiescent Current | | 1.2 | 3 | mA | $V_{IN} = 4.2V$, $V_{OUT} = 3.6V$, $I_{OUT} = 100\mu A$ |
| Shutdown Current | | | 1.5 | μA | EN/PWM = 0V, $V_{IN} = 5.5V$ |
| Oscillator Frequency | 0.42 | 0.60 | 0.78 | MHz | $V_{IN} = 3.6V$ |
| V_{FB} Reference Voltage | 0.275 | 0.306 | 0.337 | V | |
| Charge Pump Output Resistance | | 11 | 18 | Ω | FB = 0V, $V_{IN} = 3.6V$, $I_{OUT} = 20mA$, $V_{MODE} = High$ |
| V_{MODE} Threshold Voltage | 1.15 | 1.25 | 1.35 | V | V_{IN} Falling @ 25°C |
| Hysteresis for Mode Transition Voltage | | 30 | | mV _{PP} | $V_{IN} = 3.6V$ @ 25°C |
| V_{MODE} Pin Current | | 0.01 | 0.5 | μA | $V_{MODE} = 1.25$ |
| EN/PWM Logic Low | | | 0.4 | V | |
| EN/PWM Logic High | 1.6 | | | V | |
| EN/PWM Pin Current | | 0.01 | 0.5 | μA | $V_{EN/PWM} = 4.2V$ |
| FB Pin Current | | | 0.5 | μA | $V_{FB} = 1V$ |
| V_{OUT} Turn-On Time | | 175 | 500 | μs | $V_{IN} = 3.6V$, FB within 90% regulation |

PIN DESCRIPTION

| PIN NUMBER | PIN NAME | DESCRIPTION |
|------------|-------------------|---|
| 1 | V _{OUT} | Regulated charge pump output. |
| 2 | C1P | Positive terminal to the charge pump flying capacitor C2. |
| 3 | V _{IN} | Input pin for the 2.7V to 5.5V supply voltage. |
| 4 | V _{MODE} | Charge pump mode program pin. When V _{MODE} is greater than 1.25V, X1.5 charge pump is used. Otherwise, charge pump switches to X2 mode. A voltage divider shown in typical application circuit programs the V _{IN} threshold for charge pump mode switching. |
| 5 | FB | This is the feedback pin for output current or voltage regulation. The voltage of this pin is compared with an internal 306mV reference. |
| 6 | EN/PWM | Enable and PWM dimming control input. Pull this pin low to disconnect V _{OUT} from V _{IN} and shutdown the SP6682. |
| 7 | C2N | Negative terminal to the charge pump flying capacitor, C4. |
| 8 | GND | Ground reference. |
| 9 | C1N | Negative terminal to the charge pump flying capacitor, C2. |
| 10 | C2P | Positive terminal to the charge pump flying capacitor C4. |

FUNCTIONAL DIAGRAM

PERFORMANCE CHARACTERISTICS

Refer to the typical application circuit, $T_{AMB} = 25^{\circ}\text{C}$, $I_O = 60\text{mA}$ unless otherwise specified.

General Overview

The SP6682 is a current regulated charge pump ideal for converting a Li-Ion battery input for driving white LEDs used in backlighting color displays in cellular phones, PDAs, digital cameras and MP3 players. The SP6682's proprietary AutoBoost feature enables the IC to automatically transition from X1.5 boost mode to X2 boost mode based on battery input voltage for optimal efficiency and performance. The SP6682 is able to efficiently drive up to six 20mA white LEDs in parallel and maintain a constant brightness over a very wide operating voltage range (2.7V to 5.5V). The SP6682 operates with an internal 600kHz clock, enabling the use of small external components. Other features of SP6682 include PWM dimming control as well as complete input/out disconnect in shutdown. In shut down mode the IC draws less than 1.5 μA current. The output regulation is achieved by sensing the voltage at the feedback pin and modulating the switcher between the charge pump and output capacitor.

Theory of Operation

The SP6682 regulated charge pump block diagram consists of four main blocks (Voltage Reference, Mode Control, Clock Manager, Start-up and Charge-Pump Switches) and two com-

parators (V_{MODE} Comparator and V_{OUT} Comparator).

1) Voltage Reference. This block provides the 306mV and 1.25V reference voltages needed for the two comparators.

2) Mode Control. An external voltage divider connected to the V_{MODE} pin will define an input voltage to the mode comparator which sets the logic state of the mode selection outputs to the X2 or X1.5 modes. V_{MODE} is compared to a 1.25V bandgap voltage. For example, if one makes a 158K/100K divider, the mode will change at $2.58 \times 1.25 \text{ V} = 3.23\text{V}$. A comparator-based cycle by cycle regulation ensures that no mode change occurs during cycles.

3) Clock Manager. An internal 600 kHz clock is generated in this block. Depending on the mode control, the appropriate clock phasing is generated here and sent to the start-up and charge-pump switches block.

4) Start-up and Charge Pump Switches. During start-up, until the reference is established, this block keeps the charge pump inactive. During this period the output stays floating, by consequence the charge pump drivers are now referenced to V_{OUT} . Charging of the output will occur (e.g. when V_{IN} is ramped up to 4.2V, V_{OUT} ramps only up to about 3V), but not to the value of V_{IN} , protecting the White LED from experi-

encing high input voltages. Another important operation of this block is the PWM/EN dimming control, which is implemented in the delay of each pump driver, so that the enable high pulse width is proportional to the delay of the individual pump switches.

5) V_{OUT} Comparator and Output Control. A 306mV reference voltage is compared to feed-

back output voltage to control the V_{out} needed for the application. Output current is set by a bias resistor from FB pin to GND pin chosen by the relationship:

$$I_{OUT} = \frac{V_{FB}}{R_{FB}}$$

where V_{FB} = 306mV.

APPLICATION INFORMATION

Configuring the SP6682 as Voltage or Current Source

The white LED load configuration used by customers can be discrete white LEDs or a white LED module. Inside the white LED module, there may or may not be resistors in series with the white LEDs. According to the different application requirements, the SP6682 can be configured to provide solutions for these different applications, as shown in figure 9~12. Figure 9 shows using the SP6682 to drive discrete white LEDs as a current source.

The current in one white LED current is set by the ratio of the feedback pin voltage (306mV) and the bias resistor R_B. To set the operating current, R_B can be selected by:

$$R_B = \frac{V_{FB}}{I_{LED}}$$

Figure 9. Driving discrete white LEDs as current source

The current of the remaining white LEDs is set according to the similarity of the white LEDs. 3-wire white LED module with internal series resistors as shown in figure 10 can also be driven in this way.

Fig 10. 3-wire white LED module

In figure 11, SP6682 was used to drive a 2-wire white LED module without internal series resistors as a current source. The bias resistor R_B is selected to regulate the total current of the white LED module instead of the current of single LED as in figure 9.

Figure 11. Driving 2-wire white LED module as current source

In this application, the bias resistor can be selected by:

$$R_B = \frac{V_{FB}}{I_{LED(TOTAL)}}$$

where $I_{LED(TOTAL)}$ is the total operating current of all the white LEDs.

To use SP6682 as a voltage source for fixed voltage applications, a voltage divider is need to program the outup voltage, as shown in figure 12.

The output voltage is set by the ratio of the two

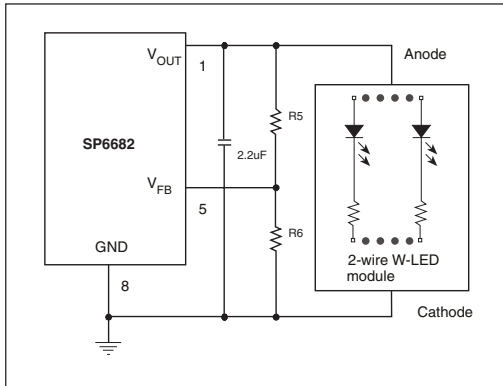

Figure 12. Driving 2-wire white LED module as voltage source

resistors and the feedback control voltage as shown by:

$$V_{OUT} = (1 + \frac{R_5}{R_6}) \cdot V_{FB}$$

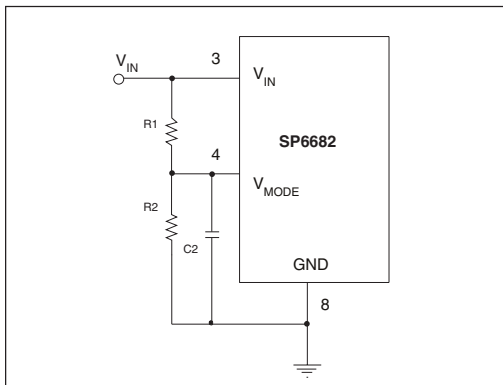

Figure 13. Programming the Vmode Resistors

Programming the Operating Mode

SP6682 can automatically change from X1.5 mode to X2 mode for highest efficiency. To use this feature, divider resistors should be chosen according to the specific application, as shown in figure 13.

The guideline for divider resistor selections is as follows. For high input voltage, the SP6682 will work in X1.5 mode. When the input voltage drops to V_{th} threshold voltage, it will switch to X2 mode automatically. The V_{th} threshold voltage for mode change can be calculated by:

$$V_{TH} = (V_F + 0.306 + m \cdot I_{LED} \cdot R_{OUT})/1.5$$

Where V_F and m are the forward voltage and number of the white LEDs, R_{out} is the output resistance of the SP6682.

The equation for the voltage divider R_1 and R_2 with $V_{MODE} = 1.25V$ is:

$$V_{TH} = 1.25V \cdot (1 + R_1/R_2)$$

which can be expressed as R_1 :

$$R_1 = (V_{TH} / 1.25 - 1) \cdot R_2$$

For the typical SP6682 application, Using $V_F=3.6V$, $m=4$, $I_{LED}=15mA$, $R_{OUT}=16\Omega$, the V_{TH} will be $3.24V$. Select $R_2=100k\Omega$, then $R_1=158k\Omega$.

Capacitor Selection

Ceramic capacitors are recommended for their inherently low ESR, which will help produce low peak to peak output ripple, and reduce high frequency spikes.

The fly capacitor controls the strength of the charge pump. Selection of the fly capacitor is a trade-off between the output voltage ripple and the output current capability. Decreasing the fly capacitor will reduce the output voltage ripple because less charge will be delivered to the output capacitor. However, smaller fly capaci-

tor leads to larger output resistance, thus decreasing the output current capability and the circuit efficiency. Place all the capacitors as close to the SP6682 as possible for layout. Increasing the value of the input and output

capacitors could further reduce the input and output ripple.

Refer to Table 1 for some suggested low ESR capacitors.

Table: 1

SUGGESTED LOW ESR CAPACITORS

| MANUFACTURERS/ TELEPHONE# | PART NUMBER | CAPACITANCE/ VOLTAGE | CAPACITOR/ SIZE/TYPE | ESR AT 100kHz |
|------------------------------|--------------------|-------------------------|-------------------------|------------------|
| TDK/847-803-6100 | C2012X5R1A225K | 2.2μF/10V | 0805/X5R | 0.030Ω |
| TDK/847-803-6100 | C2012X5R0J475K | 4.7μF/6.3V | 0805/X5R | 0.020Ω |
| MURATA/770-436-1300 | GRM188R60J225KE01D | 2.2μF/6.3V | 0603/X5R | 0.030Ω |
| MURATA/770-436-1300 | GRM219R60J475KE01D | 4.7μF/6.3V | 0805/X5R | 0.020Ω |

Brightness Control Using PWM

Dimming control can be achieved by applying a PWM control signal to the EN/PWM pin. The brightness of the white LEDs is controlled by increasing and decreasing the duty cycle of the PWM signal. While the operating frequency range of the PWM control is from 60Hz to 700Hz, the recommended maximum brightness frequency range of the PWM signal is from 60Hz to 200Hz. A repetition rate of at least 60Hz is required to prevent flicker.

Brightness Matching

For white LEDs, the forward voltage drop is a function of the operating current. However, for a given current, the forward voltage drops do not always match due to normal manufacturing tolerance, thus causing uneven brightness of the white LEDs.

In figure 14, assume high-precision bias resistors were used, the operating current ratio of two different branches can be easily derived as shown by:

$$\frac{I_1}{I_2} = \frac{V_{OUT} - V_{F1}}{V_{OUT} - V_{F2}}$$

where I_1 , I_2 are the operating current of the white LEDs, V_{F1} , V_{F2} are the forward voltage of the white LEDs.

Since the brightness of the white LED is propor-

tional to the operating current, for better brightness matching, a higher output voltage could be used. This could be done by using larger resistor, as shown in figure 14. R_{b2} is used to bias the operating current of the white LED, R_{b1} is use to increase the output voltage. Better brightness matching was achived at the cost of the power wasted on the bias resistor.

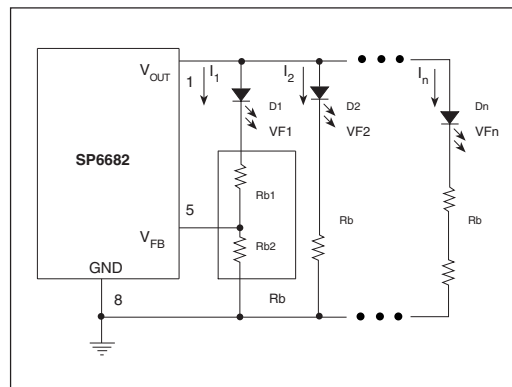

Figure 14. Increasing brightness matching

Power Efficiency

The efficiency of driving the white LEDs can be calculated by:

$$\eta = \frac{V_F \cdot I_F}{V_i \cdot I_i} = \frac{V_F \cdot I_F}{V_i \cdot (n \cdot I_F + I_Q)} \approx \frac{V_F}{V_i \cdot n}$$

Where V_i , I_i are input voltage and current V_F , I_F are the forward voltage and operating current of White LEDs I_Q is quiescent current, which is considered small compared with I_F .

n is the boost ratio (X1.5 or X2)

SP6682 High Voltage White LED Driver

The SP6682 can also be configured as a high voltage boost converter to drive more than 10 white LEDs. Figure 15 shows the schematic of

this application as well as actual data showing efficiency of >85%. By using an external inductor, MOSFET and diode, high output voltage can be generated to drive 12 white LEDs (2 branches, each branch has 6 white LEDs in series). The current through the white LEDs is determined by:

$$I_{LED} = \frac{V_{FB}}{R_1}$$
