

1Mx36 Synchronous Pipeline Burst NBL SRAM

FEATURES

- Fast clock speed: 166, 150, 133, and 100MHz
- Fast access times: 3.5ns, 3.8ns, 4.2ns, and 5.0ns
- Fast OE# access times: 3.5ns, 3.8ns, 4.2ns, and 5.0ns
- Single +3.3V \pm 5% power supply (Vcc)
- Snooze Mode for reduced-standby power
- Individual Byte Write control
- Clock-controlled and registered addresses, data I/Os and control signals
- Burst control (interleaved or linear burst)
- Packaging:
 - 119-bump BGA package
- Low capacitive bus loading

DESCRIPTION

The WEDC SyncBurst — SRAM family employs high-speed, low-power CMOS designs that are fabricated using an advanced CMOS process. WEDC's 32Mb SyncBurst SRAMs integrate two 1M x 18 SRAMs into a single BGA package to provide 1M x 36 configuration. All synchronous inputs pass through registers controlled by a positive-edge-triggered single-clock input (CLK). The NBL or No Bus Latency Memory utilizes all the bandwidth in any combination of operating cycles. Address, data inputs, and all control signals except output enable and linear burst order are synchronized to input clock. Burst order control must be tied "High or Low." Asynchronous inputs include the sleep mode enable (ZZ). Output Enable controls the outputs at any given time. Write cycles are internally self-timed and initiated by the rising edge of the clock input. This feature eliminates complex off-chip write pulse generation and provides increased timing flexibility for incoming signals.

FUNCTION DESCRIPTION

The WED2ZL361MV is an NBL SSRAM designed to sustain 100% bus bandwidth by eliminating turnaround cycle when there is transition from Read to Write, or vice versa. All inputs (with the exception of OE#, LBO and ZZ) are synchronized to rising clock edges.

All read, write and deselect cycles are initiated by the ADV# input. Subsequent burst addresses can be internally generated by the burst advance pin (ADV#). ADV# should be driven to Low once the device has been deselected in order to load a new address for next operation.

Clock Enable (CKE) pin allows the operation of the chip to be suspended as long as necessary. When CKE is high, all synchronous inputs are ignored and the internal device registers will hold their previous values. NBL SSRAM latches external address and initiates a cycle when CKE and ADV are driven low at the rising edge of the clock.

Output Enable (OE) can be used to disable the output at any given time. Read operation is initiated when at the rising edge of the clock, the address presented to the address inputs are latched in the address register, CKE is driven low, the write enable input signals WE# are driven high, and ADV# driven low. The internal array is read between the first rising edge and the second rising edge of the clock and the data is latched in the output register. At the second clock edge the data is driven out of the SRAM. During read operation OE# must be driven low for the device to drive out the requested data.

Write operation occurs when WE# is driven low at the rising edge of the clock. BW#[d:a] can be used for byte write operation. The pipe-lined NBL SSRAM uses a late-late write cycle to utilize 100% of the bandwidth. At the first rising edge of the clock, WE# and address are registered, and the data associated with that address is required two cycle later.

Subsequent addresses are generated by ADV High for the burst access as shown below. The starting point of the burst sequence is provided by the external address. The burst address counter wraps around to its initial state upon completion. The burst sequence is determined by the state of the LBO pin. When this pin is low, linear burst sequence is selected. And when this pin is high, Interleaved burst sequence is selected.

During normal operation, ZZ must be driven low. When ZZ is driven high, the SRAM will enter a Power Sleep Mode after 2 cycles. At this time, internal state of the SRAM is preserved. When ZZ returns to low, the SRAM operates after 2 cycles of wake up time.

NOTES:

1. All Address inputs must meet the specified setup and hold times for all rising clock (CLK) edges when ADV# is sampled low and CEx# is sampled valid. All other synchronous inputs must meet the specified setup and hold times whenever this device is chip selected.
2. Chip enable must be valid at each rising edge of CLK (when ADV# is Low) to remain enabled.
3. A write cycle is defined by WE# low having been registered into the device at ADV Low. A Read cycle is defined by WE# High with ADV# Low. Both cases must meet setup and hold times.

SNOOZE MODE

SNOOZE MODE is a low-current, “power-down” mode in which the device is deselected and current is reduced to I_{SBZZ} . The duration of SNOOZE MODE is dictated by the length of time Z is in a HIGH state. After the device enters SNOOZE MODE, all inputs except ZZ become gated inputs and are ignored. ZZ is an asynchronous, active HIGH input that causes the device to enter SNOOZE MODE.

When ZZ becomes a logic HIGH, I_{SBZZ} is guaranteed after the setup time t_{zz} is met. Any READ or WRITE operation pending when the device enters SNOOZE MODE is not guaranteed to complete successfully. Therefore, SNOOZE MODE must not be initiated until valid pending operations are completed.
